**The Solid-Liquid Line for Water** The phase diagram for water differs from others in one major respect that reveals a key property. Unlike almost any other substance, the solid form is *less dense* than the liquid; that is, *water expands upon freezing*. Thus, the solid-liquid line has a *negative* slope (slants to the *left* with increasing pressure): an increase in pressure converts the solid to the liquid, and the higher the pressure, the lower the temperature at which water freezes (Figure 12.11). The

vertical dashed line at  $-1^{\circ}\text{C}$  crosses the solid-liquid line, which means that ice melts with only an increase in pressure.

The triple point of water occurs at low pressure (0.006 atm). Therefore, when solid water is heated at 1.0 atm (*horizontal dashed line*), the solid-liquid line is crossed at  $0^{\circ}\text{C}$ , the normal melting point. Thus, ice melts rather than sublimes. The horizontal dashed line crosses the liquid-gas curve at  $100^{\circ}\text{C}$ , the normal boiling point.

### SAMPLE PROBLEM 12.3

### Using a Phase Diagram to Predict Phase Changes

**Problem** Use the phase diagram for carbon (*shown at right*) to describe the phase changes that a sample of carbon undergoes during the following:

(a) The sample is heated at  $10^2$  bar (99 atm) from 1000 K to 5000 K.

(b) The sample is then compressed at 5000 K to  $10^6$  bar (990,000 atm).

**Plan** We have to describe the phase changes due to heating at constant pressure ( $10^2$  bar) and then compressing at constant temperature (5000 K).

(a) Using the phase diagram, we find the starting conditions ( $10^2$  bar and 1000 K), the point labeled *a*, and draw a horizontal line from there to point *b*, at the ending conditions ( $10^2$  bar and 5000 K). We note any phase-transition curves that the line crosses.

(b) Then, from the new starting conditions at point *b* ( $10^2$  bar and 5000 K), we draw a vertical line to the ending pressure ( $10^6$  bar) and note any phase-transition curves that this line crosses.

**Solution** (a) At  $10^2$  bar and 1000 K, the sample is in the form of solid graphite. As it is heated, the graphite sublimates and becomes carbon gas (at around 4400 K).

(b) As it is compressed at 5000 K, the gas first condenses to liquid carbon (at around 300 bar), which then solidifies to diamond (at around  $3 \times 10^5$  bar).

**Check** (a) From the phase diagram, the first triple point occurs above  $10^2$  bar, so graphite will vaporize before it liquefies. (b) The liquid carbon will solidify to diamond because graphite does not exist at 5000 K under any pressure.

**Comment** Synthetic diamonds are made by compressing graphite at approximately  $7 \times 10^4$  bar and 2300 K. The process occurs at a commercially useful rate when carried out in molten nickel. Traces of nickel remain in the diamonds, which are used for grinding tools and are not of gem quality.

### FOLLOW-UP PROBLEMS

**12.3A** Describe the phase changes that a sample of carbon undergoes when it is heated at  $3 \times 10^2$  bar from 2000 K (point *c* on the phase diagram in the sample problem) to 6000 K.

**12.3B** Describe the phase changes that a sample of carbon undergoes when it is compressed at 4600 K from  $10^4$  bar (point *d* on the phase diagram in the sample problem) to  $10^6$  bar.

**SOME SIMILAR PROBLEMS** 12.27 and 12.28

## › Summary of Section 12.2

- › A heating-cooling curve depicts the change in temperature when a substance absorbs or releases heat at a constant rate. Within a phase, temperature (and average  $E_k$ ) changes. During a phase change, temperature (and average  $E_k$ ) is constant, but  $E_p$  changes. The total enthalpy change for the system is found using Hess's law.
- › In a closed container, the liquid and gas phases of a substance reach equilibrium. The vapor pressure, the pressure of the gas at equilibrium, *increases* with temperature and *decreases* with the strength of the intermolecular forces.
- › The Clausius-Clapeyron equation relates the vapor pressure to the temperature and is often used to find  $\Delta H_{\text{vap}}$ .

- › A liquid in an open container boils when the vapor pressure inside bubbles forming in the liquid equals the external pressure.
- › Solid-liquid equilibrium occurs at the melting point. Some solids sublime because they have very weak intermolecular forces.
- › The phase diagram of a substance shows the phase that is stable at any  $P$  and  $T$ , the conditions at which phase changes occur, and the conditions at the critical point and the triple point. Water differs from most substances in that its solid phase is less dense than its liquid phase, so its solid-liquid line has a negative slope.

## 12.3 TYPES OF INTERMOLECULAR FORCES

In Chapter 9, we saw that bonding (*intramolecular*) forces are due to the attraction between cations and anions (ionic bonding), nuclei and electron pairs (covalent bonding), or metal cations and delocalized electrons (metallic bonding). But the physical nature of the phases and their changes are due primarily to *intermolecular* (nonbonding) forces, which arise from the attraction between molecules with partial charges or between ions and molecules. Coulomb's law explains the relative strength of these forces:

- *Bonding forces are relatively strong* because larger charges are closer together.
- *Intermolecular forces are relatively weak* because smaller charges are farther apart.

### How Close Can Molecules Approach Each Other?

To see the minimum distance *between* molecules, consider solid  $\text{Cl}_2$ . When we measure the distances between two Cl nuclei, we obtain two different values (Figure 12.12A):

- *Bond length and covalent radius.* The shorter distance, called the *bond length*, is between *two bonded Cl atoms in the same molecule*. One-half this distance is the *covalent radius*.
- *Van der Waals distance and radius.* The longer distance is between *two nonbonded Cl atoms in adjacent molecules*. It is called the *van der Waals (VDW) distance*. At this distance, intermolecular attractions balance electron-cloud repulsions; thus, the VDW distance is as close as one  $\text{Cl}_2$  molecule can approach another. The **van der Waals radius** is one-half the closest distance between nuclei of identical *nonbonded* atoms. The VDW radius of an atom is *always larger than its covalent radius*. Like covalent radii, VDW radii decrease across a period and increase down a group (Figure 12.12B).

As we discuss intermolecular forces (also called *van der Waals forces*), consult Table 12.2, which compares them with bonding forces.

**Figure 12.12** Covalent and van der Waals radii and their periodic trends. **A**, The van der Waals (VDW) radius is one-half the closest distance between nuclei of adjacent *nonbonded* atoms ( $\frac{1}{2} \times$  VDW distance). **B**, Like covalent radii (blue quarter circles and numbers), VDW radii (red quarter-circles and numbers) increase down a group and decrease across a period.

Table 12.2

## Comparison of Bonding and Nonbonding (Intermolecular) Forces

Force	Model	Basis of Attraction	Energy (kJ/mol)	Example
<b>Bonding</b>				
Ionic		Cation–anion	400–4000	NaCl
Covalent		Nuclei–shared e <sup>-</sup> pair	150–1100	H—H
Metallic		Cations–delocalized electrons	75–1000	Fe
<b>Nonbonding (Intermolecular)</b>				
Ion–dipole		Ion charge–dipole charge	40–600	Na <sup>+</sup> ····· 
H bond		Polar bond to H–dipole charge (high EN of N, O, F)	10–40	
Dipole–dipole		Dipole charges	5–25	I—Cl·····I—Cl
Ion–induced dipole		Ion charge–polarizable e <sup>-</sup> cloud	3–15	Fe <sup>2+</sup> ·····O <sub>2</sub>
Dipole–induced dipole		Dipole charge–polarizable e <sup>-</sup> cloud	2–10	H—Cl·····Cl—Cl
Dispersion (London)		Polarizable e <sup>-</sup> clouds	0.05–40	F—F·····F—F

## Ion–Dipole Forces

When an ion and a nearby polar molecule (dipole) attract each other, an **ion–dipole force** results. The most important example takes place when an ionic compound dissolves in water. As you'll see in Chapter 13, one main reason the ions become separated is because the attractions between the ions and the oppositely charged poles of the H<sub>2</sub>O molecules are stronger than the attractions between the ions themselves.

## Dipole–Dipole Forces

In Figure 10.13, an external electric field orients gaseous polar molecules. The polar molecules in liquids and solids lie near each other, and their partial charges act as tiny electric fields and give rise to **dipole–dipole forces**: the positive pole (*blue*) of one molecule attracts the negative pole (*red*) of another (Figure 12.13). The orientation is more orderly in a solid than in a liquid because the average kinetic energy of the molecules is lower.

These forces depend on the magnitude of the molecular dipole moment. For compounds of similar molar mass, the greater the molecular dipole moment, the greater the dipole–dipole forces, so the more energy it takes to separate the molecules; thus, the boiling point is higher. Methyl chloride, for instance, has a smaller dipole

**Figure 12.13** Polar molecules and dipole–dipole forces. (Spaces between the molecules are exaggerated.)

**Figure 12.14** Dipole moment and boiling point.

moment than acetaldehyde and boils at a lower temperature (Figure 12.14). Dipole-dipole forces do not exist for nonpolar molecules.

## The Hydrogen Bond

A special type of dipole-dipole force arises between molecules that have an *H* atom bonded to a small, highly electronegative atom with lone electron pairs, specifically *N*, *O*, or *F*. The H—N, H—O, and H—F bonds are very polar. When the partially positive H of one molecule is attracted to the partially negative lone pair on the N, O, or F of another molecule, a **hydrogen bond (H bond)** forms. Thus, the atom sequence of an H bond (dotted line) is —B:⋯H—A—, where *A* and *B* are N, O, or F. Some examples are

The first two are found in pure samples of HF and NH<sub>3</sub>, respectively.

The small sizes of N, O, and F are essential to H bonding for two reasons:

1. The atoms are so electronegative that their covalently bonded H is highly positive.
2. The lone pair on the N, O, or F of the other molecule can come close to the H.

**The Significance of Hydrogen Bonding** Hydrogen bonding has a profound impact in many systems. We'll examine one effect on physical properties and preview its importance in biological systems, a topic we address in Chapters 13 and 15.

Figure 12.15 shows the effect of H bonding on the boiling points of the binary hydrides of Groups 4A(14) through 7A(17). For reasons we'll discuss shortly, boiling points rise with molar mass, as the Group 4A(14) hydrides show. However, the first member in each of the other groups—NH<sub>3</sub>, H<sub>2</sub>O, and HF—deviates enormously from this expected trend. Within samples of these substances, the molecules form strong H bonds, so it takes more energy for the molecules to separate and enter the gas phase. For example, on the basis of molar mass alone, we would

**Figure 12.15** Hydrogen bonding and boiling point. NH<sub>3</sub>, H<sub>2</sub>O, and HF have exceptionally high boiling points because they form H bonds.

expect water to boil about 200°C lower than it actually does (*red dashed line*). (In Section 12.5 we'll discuss the effects that H bonds in water have in nature.)

The significance of hydrogen bonding in biological systems cannot be emphasized too strongly. In Chapter 13, you'll see that it is a key feature in the structure and function of the biological macromolecules. As such, it is responsible for the action of many *enzymes*—the proteins that speed metabolic reactions—and for the functioning of genes, not to mention the strength of wood and texture of cotton.

### SAMPLE PROBLEM 12.4

### Drawing Hydrogen Bonds Between Molecules of a Substance

**Problem** Which of these substances exhibits H bonding? Draw examples of the H bonds between two molecules of each substance that does.

- (a)  $C_2H_6$       (b)  $CH_3OH$       (c)  $CH_3\overset{\text{O}}{\parallel}C-NH_2$

**Plan** If the molecule does *not* contain N, O, or F, it cannot form H bonds. If it contains any of these atoms covalently bonded to H, we draw two molecules in the  $-B:\cdots H-A-$  pattern.

**Solution** (a) For  $C_2H_6$ . No N, O, or F, so no H bonds can form.

(b) For  $CH_3OH$ . The H covalently bonded to the O in one molecule forms an H bond to the lone pair on the O of an adjacent molecule:

(c) For  $CH_3\overset{\text{O}}{\parallel}C-NH_2$ . Two of these molecules can form one H bond between an H bonded to N and the O, or they can form two such H bonds:

A third possibility (not shown) could be between an H attached to N in one molecule and the lone pair of N in another molecule.

**Check** The  $-B:\cdots H-A-$  sequence (with A and B either N, O, or F) is present.

**Comment** Note that H covalently bonded to C *does not form H bonds* because carbon is not electronegative enough to make the C—H bond sufficiently polar.

### FOLLOW-UP PROBLEMS

**12.4A** Which of these substances exhibits H bonding? Draw one possible example of the H bond(s) between two molecules of each substance that does.

- (a)  $CH_3\overset{\text{O}}{\parallel}C-OH$       (b)  $CH_3CH_2OH$       (c)  $CH_3\overset{\text{O}}{\parallel}CCH_3$

**12.4B** Which of these substances exhibits H bonding? Draw one possible example of the H bond(s) between two molecules of each substance that does.

- (a)  $H_2C=O$       (b)  $H_2NOH$       (c)  $O=CHCH_2OH$

**SOME SIMILAR PROBLEMS** 12.43 and 12.44

## Polarizability and Induced Dipole Forces

Even though electrons are attracted to nuclei and localized in bonding and lone pairs, we often picture them as “clouds” of negative charge because they are in constant motion. A nearby electric field can *induce* a distortion in the cloud, pulling

**Figure 12.16** Dispersion forces among nonpolar particles. **A**, When atoms are far apart, an instantaneous dipole in one atom (left) doesn't influence another. **B**, When atoms are close together, the instantaneous dipole in one atom induces a dipole in the other. **C**, The process occurs through the sample.

electron density toward a positive pole of a field or pushing it away from a negative one:

- For a nonpolar molecule, the distortion induces a temporary dipole moment.
- For a polar molecule, the distortion induces an increase in the already existing dipole moment.

In addition to charged plates connected to a battery, the source of the electric field can be the charge of an ion or the partial charges of a polar molecule.

How easily the electron cloud of an atom (or ion) can be distorted is called its **polarizability**. Smaller particles are less polarizable than larger ones because their electrons are closer to the nucleus and therefore held more tightly. Thus, we observe several trends:

- Polarizability *increases down a group* because atomic size increases and larger electron clouds are easier to distort.
- Polarizability *decreases across a period* because increasing  $Z_{\text{eff}}$  makes the atoms smaller and holds the electrons more tightly.
- Cations are *less* polarizable than their parent atoms because they are smaller; anions are *more* polarizable because they are larger.

Ion-induced dipole and dipole-induced dipole forces are the two types of charge-induced dipole forces; they are most important in solution, so we'll focus on them in Chapter 13. Nevertheless, *polarizability affects all intermolecular forces*.

## Dispersion (London) Forces

So far, we've discussed forces that depend on the existing charge of an ion or a polar molecule. But what forces cause nonpolar substances like octane, chlorine, and argon to condense and solidify? As you'll see, polarizability plays the central role in the most universal intermolecular force.

*The intermolecular force responsible for the condensed states of nonpolar substances is the **dispersion force** (or **London force**, for Fritz London, the physicist who explained its quantum-mechanical basis). Dispersion forces are present between all particles (atoms, ions, and molecules) because they result from the motion of electrons in atoms.* Let's examine key aspects of this force:

1. *Origin.* Picture one atom in a sample of, say, argon gas. Over time, its 18 electrons are distributed uniformly, so the atom is nonpolar. But at any instant, there may be more electrons on one side of the nucleus than the other, which gives the atom an *instantaneous dipole*. When a pair of argon atoms is far apart, they don't influence each other, but when close together, *the instantaneous dipole in one atom induces a dipole in its neighbor*, and they attract each other. This process spreads to other atoms and throughout the sample. At low temperatures, these attractions keep the atoms together (Figure 12.16). Thus, dispersion forces are *instantaneous dipole-induced dipole forces*.

2. *Universal presence.* While they are the *only* force existing between nonpolar particles, *dispersion forces contribute to the energy of attraction in all substances* because they exist between *all* particles. In fact, except for the forces between small, highly polar molecules or between molecules forming H bonds, the *dispersion force is the dominant intermolecular force*. Calculations show, for example, that 85% of the attraction between HCl molecules is due to dispersion forces and only 15% to dipole-dipole forces. Even for water, 75% of the attraction comes from H bonds and 25% from dispersion forces.

3. *Relative strength.* The relative strength of dispersion forces depends on the polarizability of the particles, so they are weak for small particles, like  $\text{H}_2$  and He, but stronger for larger particles, like  $\text{I}_2$  and Xe. *Polarizability depends on the number of electrons, which correlates closely with molar mass* because heavier particles are either larger atoms or molecules with more atoms and, thus, more electrons. For this reason, as molar mass increases down the Group 4A(14) hydrides (see Figure 12.15) or down the halogens or the noble gases, dispersion forces increase and so do boiling points (Figure 12.17).

7A (17)	8A (18)
<b>Formula Model</b> Molar mass Boiling point (K)	<b>He</b> 4.003 4.22
<b>F<sub>2</sub></b> 38.00 85.0	<b>Ne</b> 20.18 27.1
<b>Cl<sub>2</sub></b> 70.91 239	<b>Ar</b> 39.95 87.3
<b>Br<sub>2</sub></b> 159.8 333	<b>Kr</b> 83.80 120
<b>I<sub>2</sub></b> 253.8 458	<b>Xe</b> 131.3 165

↑ Increasing strength of dispersion forces

**Figure 12.17** Molar mass and trends in boiling point.

**Figure 12.18** Molecular shape, intermolecular contact, and boiling point.

4. *Effect of molecular shape.* For a pair of nonpolar substances with the same molar mass, a molecular shape that has more area over which electron clouds can be distorted allows stronger attractions. For example, the two five-carbon alkanes, *n*-pentane and neopentane (2,2-dimethylpropane) are isomers—same molecular formula (C<sub>5</sub>H<sub>12</sub>) but different structures and properties. *n*-Pentane is more cylindrical and neopentane more spherical (Figure 12.18). Thus, two *n*-pentane molecules make more contact than do two neopentane molecules, so dispersion forces act at more points, and *n*-pentane has a higher boiling point.

Figure 12.19 shows how to decide what intermolecular forces are present in a sample.

**Figure 12.19** Determining the intermolecular forces in a sample.

### Student Hot Spot

Student data indicate that you may struggle with identifying the type(s) of intermolecular forces in a substance. Access the Smartbook to view additional Learning Resources on this topic.

### SAMPLE PROBLEM 12.5

### Identifying the Types of Intermolecular Forces

**Problem** For each substance, identify the key bonding and/or intermolecular force(s), and predict which substance of the pair has the higher boiling point:

**Plan** We examine the formulas and structures for key differences between members of the pair: Are ions present? Are molecules polar or nonpolar? Is N, O, or F bonded to H? Do the molecules have different masses or shapes?

To rank boiling points, we consult Figure 12.19 and Table 12.2. Remember that

- Bonding forces are stronger than intermolecular forces.
- Hydrogen bonding is a strong type of dipole-dipole force.
- Dispersion forces are decisive when the difference is molar mass or molecular shape.

**Solution** (a)  $\text{MgCl}_2$  consists of  $\text{Mg}^{2+}$  and  $\text{Cl}^-$  ions held together by ionic bonding forces;  $\text{PCl}_3$ , with a trigonal pyramidal geometry, consists of polar molecules, so intermolecular dipole-dipole forces are present. The forces in  $\text{MgCl}_2$  are stronger, so it should have a higher boiling point.

(b)  $\text{CH}_3\text{NH}_2$  and  $\text{CH}_3\text{F}$  both consist of polar molecules of about the same molar mass.  $\text{CH}_3\text{NH}_2$  has N—H bonds, so it can form H bonds (*see margin*).  $\text{CH}_3\text{F}$  contains a C—F bond but no H—F bond, so dipole-dipole forces occur but not H bonds. Therefore,  $\text{CH}_3\text{NH}_2$  should have the higher boiling point.

(c)  $\text{CH}_3\text{OH}$  and  $\text{CH}_3\text{CH}_2\text{OH}$  molecules both contain an O—H bond, so they can form H bonds (*see margin*).  $\text{CH}_3\text{CH}_2\text{OH}$  has an additional — $\text{CH}_2$ — group and thus a larger molar mass, which correlates with stronger dispersion forces; therefore, it should have a higher boiling point.

(d) Hexane and 2,2-dimethylbutane are nonpolar molecules of the same molar mass but different molecular shapes (*see margin*). Cylindrical hexane molecules make more intermolecular contact than more compact 2,2-dimethylbutane molecules do, so hexane should have stronger dispersion forces and a higher boiling point.

**Check** The actual boiling points show that our predictions are correct:

(a)  $\text{MgCl}_2$  ( $1412^\circ\text{C}$ ) and  $\text{PCl}_3$  ( $76^\circ\text{C}$ )

(b)  $\text{CH}_3\text{NH}_2$  ( $-6.3^\circ\text{C}$ ) and  $\text{CH}_3\text{F}$  ( $-78.4^\circ\text{C}$ )

(c)  $\text{CH}_3\text{OH}$  ( $64.7^\circ\text{C}$ ) and  $\text{CH}_3\text{CH}_2\text{OH}$  ( $78.5^\circ\text{C}$ )

(d) Hexane ( $69^\circ\text{C}$ ) and 2,2-dimethylbutane ( $49.7^\circ\text{C}$ )

**Comment** Dispersion forces are *always* present, but in parts (a) and (b), they are much less significant than the other forces that occur.

#### FOLLOW-UP PROBLEMS

**12.5A** In each pair, identify the intermolecular forces present for each substance, and predict which substance has the *higher* boiling point:

(a)  $\text{CH}_3\text{Br}$  or  $\text{CH}_3\text{F}$     (b)  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$  or  $\text{CH}_3\text{CH}_2\text{OCH}_3$     (c)  $\text{C}_2\text{H}_6$  or  $\text{C}_3\text{H}_8$

**12.5B** In each pair, identify the intermolecular forces present for each substance, and predict which substance has the *lower* boiling point:

(a)  $\text{CH}_3\text{CHO}$  or  $\text{CH}_3\text{CH}_2\text{OH}$     (b)  $\text{SO}_2$  or  $\text{CO}_2$

(c)  $\text{H}_2\text{N}-\overset{\text{O}}{\parallel}{\text{C}}\text{CH}_2\text{CH}_3$  or  $(\text{CH}_3)_2\text{N}-\overset{\text{O}}{\parallel}{\text{C}}\text{H}$

**SOME SIMILAR PROBLEMS** 12.49–12.54

### Summary of Section 12.3

- › The van der Waals radius determines the shortest distance over which intermolecular forces operate; it is always larger than the covalent radius.
- › Intermolecular forces are much weaker than bonding (intramolecular) forces.
- › Ion-dipole forces occur between ions and polar molecules.
- › Dipole-dipole forces occur between oppositely charged poles on polar molecules.
- › Hydrogen bonding, a special type of dipole-dipole force, occurs when H bonded to N, O, or F is attracted to the lone pair of N, O, or F in another molecule.
- › Electron clouds can be distorted (polarized) in an electric field.
- › Ion- and dipole-induced dipole forces arise between a charge and the dipole it induces in another molecule.
- › Dispersion (London) forces are instantaneous dipole-induced dipole forces that occur among all particles and increase with number of electrons (molar mass). Molecular shape determines the extent of contact between molecules and can be a factor in the strength of dispersion forces.

## 12.4 PROPERTIES OF THE LIQUID STATE

Of the three states, only liquids combine the ability to flow with the effects of strong intermolecular forces. We understand this state least at the molecular level. Because of the *random* arrangement of the particles in a gas, any region of the sample is virtually identical to any other. And, different regions of a crystalline solid are identical because of the *orderly* arrangement of the particles (Section 12.6). Liquids, however, have regions that are orderly one moment and random the next. Nevertheless, many macroscopic properties, such as surface tension, capillarity, and viscosity, are well understood.

## Surface Tension

Intermolecular forces have different effects on a molecule at the surface than on one in the interior (Figure 12.20):

- An interior molecule is attracted by others on all sides.
- A surface molecule is only attracted by others below and to the sides, so it experiences a *net attraction downward*.

Therefore, to increase attractions and become more stable, a surface molecule tends to move into the interior. For this reason, *a liquid surface has the fewest molecules and, thus, the smallest area possible*. In effect, the surface behaves like a “taut skin” covering the interior.

The only way to increase the surface area is for molecules to move up by breaking attractions in the interior, which requires energy. The **surface tension** is the energy required to increase the surface area by a given amount and has units of  $\text{J/m}^2$ . This property is dependent on the intermolecular forces present and the temperature:

- In general, *the stronger the intermolecular forces between particles, the more energy it takes to increase the surface area, so the greater the surface tension* (Table 12.3). Water has a high surface tension because its molecules form multiple H bonds. *Surfactants* (surface-active agents), such as soaps, petroleum recovery agents, and fat emulsifiers, decrease the surface tension of water by congregating at the surface and disrupting the H bonds.
- Surface tension *decreases with increasing temperature*. For example, the surface tension of water is  $7.3 \times 10^{-2} \text{ J/m}^2$  at  $20^\circ\text{C}$ ,  $6.8 \times 10^{-2} \text{ J/m}^2$  at  $50^\circ\text{C}$ , and  $6.1 \times 10^{-2} \text{ J/m}^2$  at  $90^\circ\text{C}$ . At higher temperatures, the liquid molecules have increased kinetic energy with which to break attractions to molecules in the interior. Hot water is more effective than cold water at cleaning greasy dishes as the lower surface tension of hot water allows it to “wet” the surface of the dish to a greater extent. The surfactants in the soap further decrease water’s surface tension.

**Figure 12.20** The molecular basis of surface tension.

**Table 12.3**

**Surface Tension, Viscosity, and Forces Between Particles**

Substance	Formula	Surface Tension ( $\text{J/m}^2$ ) at $20^\circ\text{C}$	Viscosity ( $\text{N}\cdot\text{s/m}^2$ ) at $20^\circ\text{C}$	Major Force(s)
Diethyl ether	$\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_3$	$1.7 \times 10^{-2}$	$0.240 \times 10^{-3}$	Dipole-dipole; dispersion
Ethanol	$\text{CH}_3\text{CH}_2\text{OH}$	$2.3 \times 10^{-2}$	$1.20 \times 10^{-3}$	H bonding
Butanol	$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{OH}$	$2.5 \times 10^{-2}$	$2.95 \times 10^{-3}$	H bonding; dispersion
Water	$\text{H}_2\text{O}$	$7.3 \times 10^{-2}$	$1.00 \times 10^{-3}$	H bonding
Mercury	Hg	$48 \times 10^{-2}$	$1.55 \times 10^{-3}$	Metallic bonding

Surface tension is the cause of many familiar phenomena. Bubbles are round because this shape minimizes the surface area around the gas, and surface tension is the reason some insects can walk on water (*see photo*).

## Capillarity

The rising of a liquid against the pull of gravity through a narrow space, such as a thin tube, is called *capillary action*, or **capillarity**. Capillarity results from a competition between the intermolecular forces within the liquid (cohesive forces) and those between the liquid and the tube walls (adhesive forces). Let’s look at the difference between the capillarities of water and mercury in glass:

1. *Water in glass*. When you place a narrow glass tube in water, why does the liquid rise up the tube and form a concave meniscus? Glass is mostly silicon dioxide ( $\text{SiO}_2$ ), so water molecules form adhesive H-bonding forces with the O atoms of the glass. As a result, a thin film of water creeps up the wall. At the same time, cohesive H-bonding forces between water molecules, which give rise to surface tension, make the surface taut. These adhesive and cohesive forces combine to raise the

Because of its widespread legs, a water strider doesn’t exert enough pressure to exceed the surface tension.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

water level and produce the concave meniscus (Figure 12.21A). The liquid rises until gravity pulling down is balanced by adhesive forces pulling up.

2. *Mercury in glass.* When you place a glass tube in a dish of mercury, why does the liquid drop below the level in the dish and form a convex meniscus? The cohesive forces among the mercury atoms are metallic bonds, so they are *much* stronger than the mostly dispersion adhesive forces between mercury and glass. As a result, the liquid pulls away from the walls. At the same time, the surface atoms are being pulled toward the interior by mercury's high surface tension, so the level drops. These combined forces produce the convex meniscus seen in a laboratory barometer (Figure 12.21B).

Capillarity plays a key role in many everyday events. The adhesive (dipole–induced dipole) forces between water and a nonpolar surface are much weaker than the cohesive (H-bond) forces within water. As a result, water pulls away from a nonpolar surface and forms beaded droplets, as on a freshly waxed car or on the waxy coating of a leaf after a rainfall. Even more familiar, after a shower, capillary action draws water away from your body through the closely spaced fibers in the cotton towel, which is made of cellulose molecules, so the water molecules also form H bonds with the —OH groups of cellulose.

## Viscosity

**Viscosity** is the resistance of a fluid to flow, and it results from intermolecular attractions that impede the movement of molecules around and past each other. Both gases and liquids flow, but liquid viscosities are *much* higher because the much shorter distances between the particles of a liquid result in many more points for intermolecular forces to act. Intermolecular forces, temperature, and molecular shape influence viscosity:

- In general, *the stronger the intermolecular forces between particles, the higher the viscosity* (Table 12.3) since stronger attractions prevent molecules from moving past each other freely.
- *Viscosity decreases with increasing temperature* (Table 12.4). Faster moving molecules overcome intermolecular forces more easily, so the resistance to flow decreases with increasing temperature. Next time you heat cooking oil, watch the oil flow more easily and spread out in the pan as it warms.
- *Viscosity is affected by molecular shape.* Small, spherical molecules make little contact and pour easily, like buckshot from a bowl. Long molecules make more contact and become entangled and pour slowly, like cooked spaghetti from a bowl. Thus, given the same types of intermolecular forces, liquids consisting of longer molecules have higher viscosities. As shown in Table 12.3, the viscosity of the longer butanol molecule is greater than that of the shorter ethanol molecule.

**Table 12.4** Viscosity of Water at Several Temperatures

Temperature (°C)	Viscosity (N·s/m <sup>2</sup> )*
20	1.00×10 <sup>-3</sup>
40	0.65×10 <sup>-3</sup>
60	0.47×10 <sup>-3</sup>
80	0.35×10 <sup>-3</sup>

\*The units of viscosity are newton-seconds per square meter.

To protect engine parts during long drives, motor oils contain *polymeric viscosity improvers*. As the oil warms, these additive molecules change from compact spheres to long strands that become tangled with the long hydrocarbon molecules of the oil. Greater dispersion forces increase the viscosity to compensate for the thinning of the oil due to heating.

### › Summary of Section 12.4

- › Surface tension is a measure of the energy required to increase a liquid's surface area. Greater intermolecular forces within a liquid create higher surface tension.
- › Capillarity, the rising of a liquid through a narrow space, occurs when the forces between a liquid and a surface (adhesive) are greater than those in the liquid (cohesive).
- › Viscosity, the resistance to flow, depends on molecular shape and decreases with temperature. Stronger intermolecular forces create higher viscosity.

## 12.5 THE UNIQUENESS OF WATER

Water is absolutely amazing stuff, with some of the most unusual properties of any substance, but it is so familiar we take it for granted. Like any substance, its properties arise inevitably from those of its atoms. Each O and H atom attains a filled outer level by sharing electrons in single bonds. With two bonding pairs and two lone pairs around O and a large electronegativity difference in each O—H bond, the H<sub>2</sub>O molecule is bent and highly polar. This arrangement is crucial because it allows each molecule to engage in four H bonds with its neighbors (Figure 12.22). From these basic atomic and molecular facts emerges some unique and remarkable macroscopic behavior.

### Solvent Properties of Water

The *great solvent power* of water results from its polarity and H-bonding ability:

- It dissolves ionic compounds through ion-dipole forces that separate the ions from the solid and keep them in solution (see Figure 4.2).
- It dissolves polar nonionic substances, such as ethanol (CH<sub>3</sub>CH<sub>2</sub>OH) and glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>), by H bonding.
- It dissolves nonpolar atmospheric gases to a limited extent through dipole-induced dipole and dispersion forces.

Water is the environmental and biological solvent, forming the complex solutions we know as oceans, lakes, and cellular fluid. Aquatic animals could not survive without dissolved O<sub>2</sub>, nor could aquatic plants without dissolved CO<sub>2</sub>. Tiny marine animals form coral reefs made of carbonates from dissolved CO<sub>2</sub> and HCO<sub>3</sub><sup>-</sup>. Life began in a “primordial soup,” an aqueous mixture of simple molecules from which emerged larger molecules capable of self-sustaining reactions. From a chemical point of view, all organisms, from bacteria to humans, are highly organized systems of membranes enclosing and compartmentalizing complex aqueous solutions.

### Thermal Properties of Water

When a substance is heated, some of the added energy increases average molecular speed, some increases molecular vibration and rotation, and some is used to overcome intermolecular forces.

1. *Specific heat capacity.* Because water has so many strong H bonds, its *specific heat capacity* is higher than that of any common liquid. With oceans covering 70% of Earth's surface, daytime energy from the Sun causes relatively small changes in temperature, allowing life to survive. On the waterless, airless Moon, temperatures range from 100°C to -150°C during a complete lunar day. Even in Earth's deserts, day-night temperature differences of 40°C are common.

2. *Heat of vaporization.* Numerous strong H bonds give water a very *high heat of vaporization*. Two examples show why this is crucial. The average adult has 40 kg of

**Figure 12.22** H-bonding ability of water. One H<sub>2</sub>O molecule can form four H bonds to other molecules, resulting in a tetrahedral arrangement.

A

B

Source: (B) © Scott Camazine/Science Source

body water and generates about 10,000 kJ of heat a day from metabolism. If this heat were used to increase the average  $E_k$  of water molecules in the body, the rise in body temperature of tens of degrees would mean immediate death. Instead, the heat is converted to  $E_p$  as it breaks H bonds and evaporates sweat, resulting in a stable body temperature and minimal loss of body fluid. On a planetary scale, the Sun's energy vaporizes ocean water in warm latitudes, and the potential energy is released as heat to warm cooler regions when the vapor condenses to rain. This global-scale cycling of water powers many weather patterns.

## Surface Properties of Water

Hydrogen bonding is also responsible for water's *high surface tension* and *high capillarity*. Except for some molten metals and salts, water has the highest surface tension of any liquid. It keeps plant debris resting on a pond surface, providing shelter and nutrients for fish and insects. High capillarity means water rises through the tiny spaces between soil particles, so plant roots can absorb deep groundwater during dry periods.

## The Unusual Density of Solid Water

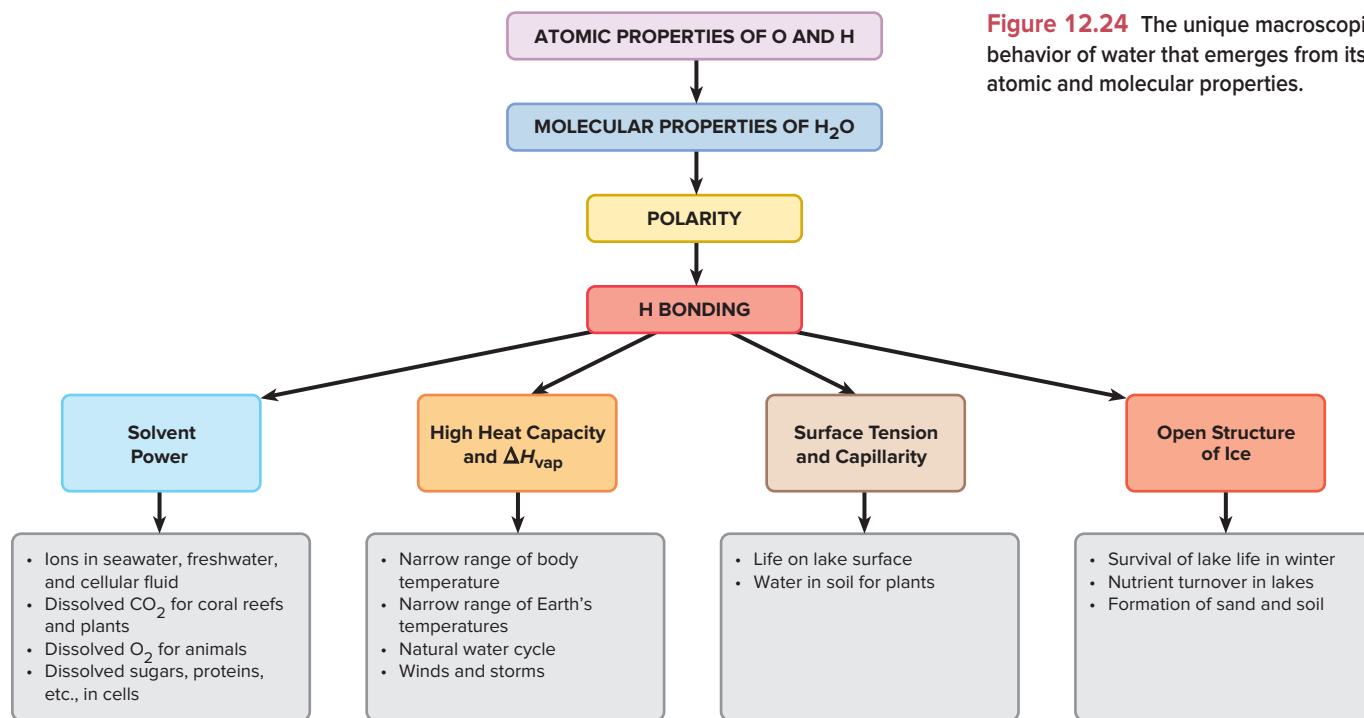

In the solid state, the tetrahedral arrangement of H-bonded water molecules (see Figure 12.22) leads to the hexagonal, *open structure* of ice (Figure 12.23A), and the symmetrical beauty of snowflakes (Figure 12.23B) reflects this hexagonal organization. The large spaces within ice make *the solid less dense than the liquid* and explain the negative slope of the solid-liquid line in the phase diagram for water (see Figure 12.11). As pressure is applied, some H bonds break, so the crystal structure is disrupted, and the ice liquefies. When ice melts at  $0^\circ\text{C}$ , the loosened molecules pack much more closely, filling spaces in the collapsing solid structure. As a result, liquid water is most dense (1.000 g/mL) at around  $4^\circ\text{C}$  ( $3.98^\circ\text{C}$ ). With more heating, the density decreases through normal thermal expansion. This behavior has major effects in nature:

- *Surface ice of lakes.* When the surface of a lake freezes in winter, the ice floats. If the solid were denser than the liquid, as is true for nearly every other substance, the surface water would freeze and sink until the entire lake was solid. Aquatic life would not survive from year to year.
- *Nutrient turnover.* As lake water becomes colder in early winter, it becomes more dense *before* it freezes. Similarly, in spring, less dense ice thaws to form more dense water *before* the water expands. During both of these seasonal density changes, the top layer of water reaches maximum density first and sinks. The next layer of water rises because it is slightly less dense, reaches  $4^\circ\text{C}$ , and likewise sinks. This alternation of sinking and rising distributes nutrients and dissolved oxygen.
- *Soil formation.* When rain fills crevices in rocks and freezes, an outward force is applied that is relieved when the ice melts. In time, this repeated freeze-thaw stress cracks the rock. Over eons, this effect helps produce sand and soil.

The far-reaching consequences of the properties of water illustrate chemistry's central theme: the macroscopic world we know is the cumulative outcome of the atomic world we seek to know (Figure 12.24).

## › Summary of Section 12.5

- › The atomic properties of H and O result in water's bent molecular shape, polarity, and H-bonding ability.
- › These properties give water the ability to dissolve many ionic and polar compounds.
- › Water's high specific heat capacity and heat of vaporization give Earth and its organisms a narrow temperature range.
- › Water's high surface tension and capillarity are essential to plants and animals.
- › Because water expands on freezing, lake life survives in winter, nutrients mix from seasonal density changes, and soil forms through freeze-thaw stress on rocks.

## 12.6 THE SOLID STATE: STRUCTURE, PROPERTIES, AND BONDING

Stroll through a museum's mineral collection, and you'll be struck by the variety and beauty of crystalline solids. In this section, we discuss the structural features of these and other solids and the intermolecular forces that create them. We also consider the main bonding model that explains many properties of solids.

### Structural Features of Solids

We can divide solids into two broad categories:

- **Crystalline solids** have well-defined shapes because their particles—atoms, molecules, or ions—occur in an orderly arrangement (Figure 12.25).
- **Amorphous solids** have poorly defined shapes because their particles do not have an orderly arrangement throughout a sample.

**The Crystal Lattice and the Unit Cell** The particles in a crystal are packed tightly in an orderly, three-dimensional array. As the simplest case, consider the particles as

**Figure 12.25** The beauty of crystalline solids. **A**, Wulfenite. **B**, Barite. **C**, Beryl (emerald). **D**, Quartz (amethyst).

**Figure 12.26** The crystal lattice and the unit cell. **A**, A small portion of a lattice is shown as points connected by lines, with a unit cell (colored). **B**, A checkerboard as a two-dimensional analogy for a lattice.

*identical* spherical atoms, and imagine a point at the center of each. The collection of points forms a regular pattern called the crystal **lattice**. The lattice consists of *all points with identical surroundings*; that is, there would be no way to tell if you moved from one lattice point to another.

Figure 12.26A shows a portion of a lattice and the **unit cell**, the *smallest* portion that yields the crystal if it is repeated in all directions. A two-dimensional analogy for a unit cell and the resulting crystal lattice is a checkerboard (Figure 12.26B), a section of tiled floor, or any pattern that is constructed from a repeating unit.

There are 7 crystal systems and 14 types of unit cells that occur in nature, but we will be concerned primarily with the *cubic system*. The solid states of a majority of metallic elements, some covalent compounds, and many ionic compounds occur as cubic lattices. A key parameter of any lattice is the **coordination number**, the number of *nearest* neighbors of a particle in a crystal. There are three types of cubic unit cells:

1. In the **simple cubic unit cell** (Figure 12.27A), the centers of eight identical particles define the corners of a cube (shown in the expanded view, *top row*). The particles touch along the cube edges (see the space-filling view, *second row*), but they do not touch diagonally along the cube faces or through its center. An expanded portion of the crystal (*third row*) shows that the coordination number of each particle is 6: four in its own layer, one in the layer above, and one in the layer below.
2. In the **body-centered cubic unit cell** (Figure 12.27B), identical particles lie at each corner *and* in the center of the cube. Those at the corners do not touch each other, but they all touch the one in the center. Each particle is surrounded by eight nearest neighbors, four above and four below, so the coordination number is 8.
3. In the **face-centered cubic unit cell** (Figure 12.27C), identical particles lie at each corner *and* in the center of each face but not in the center of the cube. Particles at the corners touch those in the faces but not each other. The coordination number is 12.

How many particles make up a unit cell? For particles of the same size, *the higher the coordination number, the greater the number of particles in a given volume*. Since one unit cell touches another, with no gaps, a particle at a corner or face is *shared* by adjacent cells. In the cubic unit cells, the particle at each corner is part of eight adjacent cells (Figure 12.27, *third row*), so one-eighth of each particle belongs to each cell (*bottom row*). There are eight corners in a cube, so

- A simple cubic unit cell contains  $8 \times \frac{1}{8}$  particle = 1 particle.
- A body-centered cubic unit cell contains  $8 \times \frac{1}{8}$  particle = 1 particle plus 1 particle in the center, for a total of 2 particles.
- A face-centered cubic unit cell contains  $8 \times \frac{1}{8}$  particle = 1 particle plus one-half particle in each of the six faces  $6 \times \frac{1}{2}$  particle = 3 particles, for a total of 4 particles.

**Figure 12.27** The three cubic unit cells. **A**, Simple cubic unit cell. **B**, Body-centered cubic unit cell. **C**, Face-centered cubic unit cell. *Top row:* Cubic arrangements of atoms in expanded view. *Second row:* Space-filling view of these cubic arrangements. All atoms are identical but, for clarity, corner atoms are blue, body-centered atoms pink, and face-centered atoms yellow. *Third row:* A unit cell (shaded blue) in an expanded portion of the crystal. The number of nearest neighbors around one particle (dark blue in center) is the coordination number. *Bottom row:* The total numbers of atoms in the actual unit cells. The simple cubic has one atom, the body-centered has two, and the face-centered has four.

### SAMPLE PROBLEM 12.6

### Determining the Number of Particles per Unit Cell and the Coordination Number

**Problem** For each of the crystalline solids shown in the margin on the next page, determine the number of atoms (or ions) per unit cell and the coordination number.

**Plan** To determine the number of particles (atoms or ions) in a unit cell, we count the number of particles at the corners, in the faces, and within the body of the cell. The

eight corners are shared by eight other cells for a total of  $8 \text{ corners} \times \frac{1}{8}$  particle per corner, or 1 particle; particles in the body of a cell are in that cell only; particles in the faces are shared by two cells,  $6 \text{ faces} \times \frac{1}{2}$  particle per face, or 3 particles. We count the number of nearest neighboring particles to obtain the coordination number.

**Solution** (a) Palladium metal adopts a face-centered cubic unit cell:

$$\text{Atoms/unit cell} = (8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4 \text{ atoms}$$

The coordination number is 12.

(b) Copper(I) iodide has a unit cell that can be viewed as a face-centered cubic array of  $\text{Cu}^+$  ions interpenetrating a face-centered cubic array of  $\text{I}^-$  ions:

$$\text{Cu}^+ \text{ ions within the body of the unit cell} = 4$$

$$\text{I}^- \text{ ions/unit cell} = (8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4 \text{ Cu}^+ \text{ and } 4 \text{ I}^- \text{ ions}$$

Each ion is surrounded by four of the oppositely charged ions: coordination number is 4.

(c) Molybdenum metal adopts a body-centered cubic cell:

$$\text{Atoms/unit cell} = (8 \times \frac{1}{8}) + (1 \times 1) = 2 \text{ atoms}$$

The coordination number is 8.

**Check** Using Figure 12.27, we see that the values are correct.

### FOLLOW-UP PROBLEMS

**12.6A** For each of the following crystalline solids, determine the number of atoms (or ions) per unit cell and the coordination number:

**12.6B** For each of the following crystalline solids, determine the number of atoms (or ions) per unit cell and the coordination number:

**SOME SIMILAR PROBLEMS** 12.87, 12.96, 12.97, 12.98(a), and 12.99(a)

The efficient packing of fruit.

Source: © Bryan Busovicki/Shutterstock.com

**Packing Efficiency and the Creation of Unit Cells** Unit cells result from the ways atoms pack together, which are similar to the ways that macroscopic spheres—marbles, golf balls, fruit—are packed (*see photo*). Let's pack *identical* spheres to create the three cubic unit cells and the hexagonal unit cell and determine the **packing efficiency**, the percentage of the total volume of the unit cell occupied by the spheres themselves:

1. *The simple cubic unit cell.* When we arrange the first layer of spheres in vertical and horizontal rows, large diamond-shaped spaces are formed (Figure 12.28A, *cutaway portion*). If we place the next layer of spheres *directly above* the first, we obtain an arrangement based on the *simple* cubic unit cell (Figure 12.28B). The spheres occupy only 52% of the unit-cell volume, so 48% is empty space between them. This is a very inefficient way to pack spheres, so neither fruit nor atoms are typically packed this way.

2. *The body-centered cubic unit cell.* Rather than placing the second layer (colored *green* for clarity) directly above the first, we use space more efficiently by placing its spheres over the diamond-shaped spaces in the first layer (Figure 12.28C). Then we pack the third layer onto the diamond-shaped spaces in the second, which makes the first and third layers line up vertically. This arrangement is based on the *body-centered* cubic unit cell, and its packing efficiency, at 68%, is much higher than that of the

**Figure 12.28** Packing spheres to obtain three cubic and hexagonal unit cells. **A**, In the first layer, each sphere lies next to another horizontally and vertically; note the large diamond-shaped spaces (see cutaway). **B**, If the spheres in the next layer lie directly over those in the first, the packing is based on the simple cubic unit cell (pale orange cube, lower right corner). **C**, If the spheres in the next layer lie in the diamond-shaped spaces of the first layer, the packing is based on the body-centered cubic unit cell (lower right corner). **D**, The closest possible packing of the first layer (layer *a*, orange) is obtained by shifting every other row in part A to obtain smaller triangular spaces. The spheres of the second layer (layer *b*, green) are placed above these spaces; note the orange and white spaces that result. **E**, When the third layer (next layer *a*, orange) is placed over the orange spaces, we obtain an *abab...* pattern and the hexagonal unit cell. **F**, When the third layer (layer *c*, blue) covers the white spaces, we get an *abcabc...* pattern and the face-centered cubic unit cell.

simple cubic unit cell. Several metallic elements, including chromium, iron, and all the Group 1A(1) elements, have a crystal structure based on this unit cell.

3. *The hexagonal and face-centered cubic unit cells.* Spheres are packed most efficiently in these cells. First, in the bottom layer (labeled *a*, orange), we shift every other row laterally so that the large diamond-shaped spaces become smaller triangular spaces. Then we place the second layer (*b*, green) over these spaces (Figure 12.28D).

In layer *b*, notice that some spaces are orange because they lie above spheres in layer *a*, whereas other spaces are white because they lie above spaces in layer *a*.

We can place the third layer in either of two ways, giving rise to two different unit cells:

- *Hexagonal unit cell.* If we place the third layer of spheres (*orange*) over the orange spaces (look down and left to Figure 12.28E), they lie directly over the spheres in layer *a*. Every other layer is placed identically (an *abab...* layering pattern), and we obtain **hexagonal closest packing**, which is based on the *hexagonal* unit cell.
- *Face-centered unit cell.* If we place the third layer of spheres (*blue*) over the white spaces in layer *b* (look down and right to Figure 12.28F), the placement is different from layers *a* and *b* (an *abcabc...* pattern), and we obtain **cubic closest packing**, which is based on the *face-centered cubic* unit cell.

The packing efficiency with both hexagonal and cubic closest packing is 74%, and the coordination number of both types of unit cells is 12. Most metallic elements crystallize in one or the other of these arrangements. Magnesium, titanium, and zinc are some that adopt the hexagonal structure; nickel, copper, and lead adopt the cubic closest packing structure, as do many ionic compounds and other substances, such as CO<sub>2</sub>, CH<sub>4</sub>, and most noble gases.

In Sample Problem 12.7, we use the density of a metal and our knowledge of unit cells to find an atomic radius.

### SAMPLE PROBLEM 12.7

### Determining Atomic Radius

**Problem** Barium is the largest nonradioactive alkaline earth metal. It has a body-centered cubic unit cell and a density of 3.62 g/cm<sup>3</sup>. What is the atomic radius of barium? (Volume of a sphere:  $V = \frac{4}{3}\pi r^3$ .)

**Plan** An atom is spherical, so we can find its radius from its volume. If we multiply the reciprocal of density (volume/mass) by the molar mass (mass/mole), we find the volume/mole of Ba metal. The metal crystallizes in the body-centered cubic structure, so 68% of this volume is occupied by 1 mol of the Ba atoms themselves (see Figure 12.28C). Dividing by Avogadro's number gives the volume of one Ba atom, from which we find the radius. (See the road map.)

**Solution** Combining steps to find the volume of 1 mol of Ba metal:

$$\text{Volume/mole of Ba metal} = \frac{1}{\text{density}} \times \mathcal{M} = \frac{1 \text{ cm}^3}{3.62 \text{ g Ba}} \times \frac{137.3 \text{ g Ba}}{1 \text{ mole Ba}} = 37.9 \text{ cm}^3/\text{mol Ba}$$

Finding the volume (cm<sup>3</sup>) of 1 mol of Ba atoms:

$$\begin{aligned} \text{Volume/mole of Ba atoms} &= \text{cm}^3/\text{mol Ba} \times \text{packing efficiency} \\ &= 37.9 \text{ cm}^3/\text{mol Ba} \times 0.68 \\ &= 26 \text{ cm}^3/\text{mol Ba atoms} \end{aligned}$$

Finding the volume of one Ba atom:

$$\begin{aligned} \text{Volume of Ba atom} &= \frac{26 \text{ cm}^3}{1 \text{ mol Ba atoms}} \times \frac{1 \text{ mol Ba atoms}}{6.022 \times 10^{23} \text{ Ba atoms}} \\ &= 4.3 \times 10^{-23} \text{ cm}^3/\text{Ba atom} \end{aligned}$$

Finding the atomic radius of Ba from the volume of a sphere:

$$V \text{ of Ba atom} = \frac{4}{3}\pi r^3 \quad \text{so} \quad r^3 = \frac{3V}{4\pi}$$

Thus,

$$r = \sqrt[3]{\frac{3V}{4\pi}} = \sqrt[3]{\frac{3(4.3 \times 10^{-23} \text{ cm}^3)}{4 \times 3.14}} = 2.2 \times 10^{-8} \text{ cm}$$

**Check** The order of magnitude is correct for an atom ( $\sim 10^{-8} \text{ cm} \approx 10^{-10} \text{ m}$ ). The actual value for barium is, in fact,  $2.22 \times 10^{-8} \text{ cm}$  (see Figure 8.13).

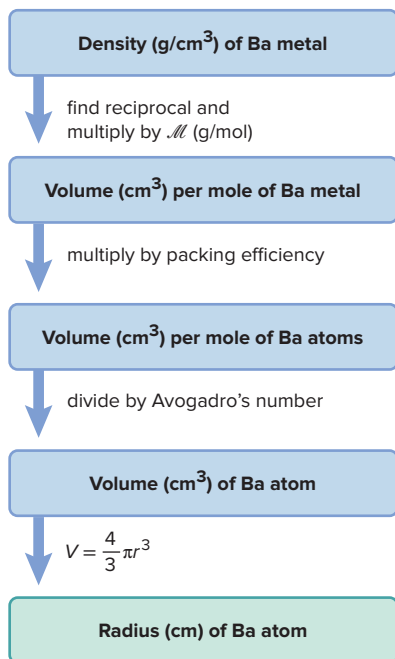

### FOLLOW-UP PROBLEMS

**12.7A** Cobalt has a face-centered cubic unit cell and an atomic radius of 125 pm. Calculate the density of cobalt metal.

**12.7B** Iron crystallizes in a body-centered cubic structure. The volume of one Fe atom is  $8.38 \times 10^{-24} \text{ cm}^3$ , and the density of Fe is 7.874 g/cm<sup>3</sup>. Calculate an approximate value for Avogadro's number.

**SOME SIMILAR PROBLEMS** 12.88 and 12.89

### Road Map

**Figure 12.29** Edge length and atomic (ionic) radius in the three cubic unit cells.

Our understanding of crystal structures comes from our ability to “see” them. Two techniques for visualizing crystal structures are described in Tools of the Laboratory on the next page.

The edge length of the unit cell is obtained from x-ray crystallography. We can then apply the Pythagorean theorem and some arithmetic to find atomic (or ionic) radii in the three cubic unit cells (Figure 12.29). Sample Problem 12.8 applies this approach.

### SAMPLE PROBLEM 12.8

### Determining Atomic Radius from the Unit Cell

**Problem** Copper adopts cubic closest packing, and the edge length of the unit cell is 361.5 pm. What is the atomic radius of copper?

**Plan** Cubic closest packing gives a face-centered cubic unit cell, and we know the edge length. From Figure 12.29, with  $A = 361.5$  pm, we solve for  $r$ .

**Solution** Using the Pythagorean theorem to find  $C$ , the diagonal of the cell’s face:

$$C = \sqrt{A^2 + B^2}$$

The unit cell is a cube, so  $A = B$ . Therefore,

$$C = \sqrt{2A^2} = \sqrt{2(361.5 \text{ pm})^2} = 511.2 \text{ pm}$$

Finding  $r$ :  $C = 4r$ . Therefore,

$$r = 511.2 \text{ pm}/4 = 127.8 \text{ pm.}$$

We can combine these steps by using the equation presented in Figure 12.29:

$$A = \sqrt{8}r$$

$$r = 361.5 \text{ pm}/\sqrt{8} = 127.8 \text{ pm}$$

**Check** Rounding and quickly checking the math gives

$$C = \sqrt{(4 \times 10^2 \text{ pm})^2} = \sqrt{(16 \times 10^4 \text{ pm}^2)}$$

or  $\sim 500\text{--}600$  pm; thus,  $r \approx 125\text{--}150$  pm. The actual value for copper is 128 pm (see Figure 8.13).

### FOLLOW-UP PROBLEMS

**12.8A** Iron crystallizes in a body-centered cubic structure. If the atomic radius of Fe is 126 pm, find the edge length (in nm) of the unit cell.

**12.8B** Aluminum crystallizes in a cubic closest packed structure. If the edge length of the unit cell is 0.405 nm, find the atomic radius (in pm).

**SOME SIMILAR PROBLEMS** 12.92 and 12.93

Various tools exist for measuring atomic-scale dimensions, and two of the most powerful are **x-ray diffraction analysis** and **scanning tunneling microscopy**.

### X-Ray Diffraction Analysis

In Chapter 7, we saw how diffraction patterns of bright and dark regions appear when light passes through slits spaced as far apart as the wavelength (see Figure 7.5). X-ray wavelengths are about the same size as the spaces between layers of spheres in a crystal, so we use the spaces as “slits” to diffract x-rays.

As one example, let’s use this approach to measure the distance ( $d$ ) between two adjacent layers of atoms in a simplified lattice (Figure B12.1). Two waves impinge on the crystal at an angle  $\theta$  and are diffracted at that angle by the layers. When the

**Figure B12.1** Diffraction of x-rays by crystal planes.

first wave strikes the top layer and the second strikes the next layer, they are *in phase* (peaks aligned with peaks and troughs with troughs). If they are still in phase after being diffracted, they form a spot on a photographic plate. This will occur only if the additional distance traveled by the second wave ( $DE + EF$  in the figure) is a whole number of wavelengths,  $n\lambda$ , where  $n$  is a positive integer referred to as the *order* of the diffraction. From trigonometry, we find that

$$n\lambda = 2d \sin \theta$$

where  $\theta$  is the angle of incoming light and  $d$ , the unknown, is the distance between layers. This is the *Bragg equation*, named for W. H. Bragg and his son W. L. Bragg, who shared the Nobel Prize in physics in 1915 for their work on crystal structure analysis.

Rotating the crystal changes  $\theta$  and produces different sets of spots. Eventually, the complete diffraction pattern reveals distances and angles in the lattice (Figure B12.2). X-ray diffraction analysis is used in many studies, but its greatest recent impact is uncovering the structures of DNA and proteins.

### Scanning Tunneling Microscopy

This technique, invented by Gerd Binnig and Heinrich Rohrer, who won the Nobel Prize in physics in 1986, is used to observe surfaces. It is based on the idea that an electron has a small, but finite, probability of being so far from its nucleus that it can move (“tunnel”) closer to another atom.

In practice, an extremely sharp tungsten-tipped probe, the source of the tunneling electrons, is placed very close to (about 0.5 nm from) the surface under study. A small applied electric

**Figure B12.2** Formation of an x-ray diffraction pattern of the protein hemoglobin. **A**, A sample of crystalline protein is rotated to obtain different angles of incoming and diffracted x-rays. **B**, The diffraction pattern is a complex series of spots. **C**, Computerized analysis provides a picture of the molecule.

potential increases the probability that the electrons will tunnel across this minute gap. The probe moves tiny distances up and down to maintain the constant current across the gap, thus following the surface at the atomic scale. This movement is monitored electronically, and after many scans, a three-dimensional map of the surface is obtained. The method has revealed images of atoms and molecules coated on surfaces and is being used to study the nature of defects and many other surface features (Figure B12.3).

### Problems

**B12.1** X-rays of wavelength  $\lambda = 0.709 \times 10^{-10}$  m undergo a first-order ( $n = 1$ ) diffraction of  $11.6^\circ$  when aimed at crystalline nickel. What is the spacing between layers of Ni atoms?

**B12.2** A first-order ( $n = 1$ ) diffraction of x-rays aimed at a crystal of NaCl occurs at  $15.9^\circ$ .

(a) What is the wavelength (in pm) of the x-rays?

(b) At what angle would a second-order ( $n = 2$ ) diffraction appear?

**Figure B12.3** A scanning tunneling micrograph of cesium atoms (red) on gallium arsenide.

## Types and Properties of Crystalline Solids

The five most important types of solids are defined by the type(s) of particle(s) in the crystal (Table 12.5). We'll highlight interparticle forces and physical properties.

**Table 12.5**

**Characteristics of the Major Types of Crystalline Solids**

Type	Particle(s)	Interparticle Forces	Physical Properties	Examples [mp, °C]
Atomic	Atoms	Dispersion	Soft, very low mp, poor thermal and electrical conductors	Elements in Group 8A(18) (Ne [−249] to Rn [−71])
Molecular	Molecules	Dispersion, dipole-dipole, H bonds	Fairly soft, low to moderate mp, poor thermal and electrical conductors	<i>Nonpolar*</i> O <sub>2</sub> [−219], C <sub>4</sub> H <sub>10</sub> [−138] Cl <sub>2</sub> [−101], C <sub>6</sub> H <sub>14</sub> [−95], P <sub>4</sub> [44.1] <i>Polar</i> SO <sub>2</sub> [−73], CHCl <sub>3</sub> [−64], HNO <sub>3</sub> [−42], H <sub>2</sub> O [0.0], CH <sub>3</sub> COOH [17]
Ionic	Positive and negative ions	Ion-ion attraction	Hard and brittle, high mp, good thermal and electrical conductors when molten	NaCl [801] CaF <sub>2</sub> [1423] MgO [2852]
Metallic	Atoms	Metallic bond	Soft to hard, low to very high mp, excellent thermal and electrical conductors, malleable and ductile	Na [97.8] Zn [420] Fe [1535]
Network covalent	Atoms	Covalent bond	Very hard, very high mp, usually poor thermal and electrical conductors	SiO <sub>2</sub> (quartz) [1610] C (diamond) [~4000]

\*Nonpolar molecular solids are arranged in order of increasing molar mass. Note the correlation with increasing melting point (mp).

**Figure 12.30** Cubic closest packing of argon (face-centered cubic unit cell).

**Figure 12.31** Cubic closest packing (face-centered unit cell) of  $\text{CH}_4$ .

**Atomic Solids** Individual atoms held together only by *dispersion forces* form an **atomic solid** and the noble gases [Group 8A(18)] are the only substances that form such solids. The very weak forces among the atoms mean melting and boiling points and heats of vaporization and fusion are all very low, rising smoothly with increasing molar mass. Argon crystallizes in a cubic closest packed structure (Figure 12.30), as do the other noble gases.

**Molecular Solids** In the many thousands of **molecular solids**, individual molecules occupy the lattice points. Various combinations of dipole-dipole, dispersion, and H-bonding forces account for a wide range of physical properties. Dispersion forces in nonpolar substances lead to melting points that generally increase with molar mass (Table 12.5). Among polar molecules, dipole-dipole forces and, where possible, H bonding occur. Most molecular solids have much higher melting points than atomic solids (noble gases) but much lower melting points than other types of solids. Methane crystallizes in a face-centered cubic structure with the center of each carbon as the lattice point (Figure 12.31).

**Ionic Solids** To maximize attractions in a binary **ionic solid**, cations are surrounded by as many anions as possible, and vice versa, with *the smaller of the ions (usually the cation) lying in the spaces (holes) formed by the packing of the larger (usually the anion)*. The unit cell is the smallest portion that maintains the composition; that is, *the unit cell has the same cation/anion ratio as the empirical formula*.

As a result of cation-anion contact, the interparticle forces (ionic bonds) are *much* stronger than the van der Waals forces in atomic or molecular solids. The properties of ionic solids are a direct consequence of the *fixed ion positions* and *very strong attractive forces*, which create a high lattice energy. Thus, ionic solids typically have high melting points and low electrical conductivities. When a large quantity of heat is supplied and the ions gain enough kinetic energy to break free of their positions, the solid melts and the mobile ions conduct a current. Ionic compounds are hard because only a strong external force can change the relative positions of the huge number of ions attracting one another. If enough force *is* applied to move them, ions of like charge are brought near each other, and their repulsions crack the crystal (see Figure 9.9).

Ionic solids often adopt cubic closest packed crystal structures. Let's consider two examples with a 1/1 ratio of ions and then two with a 2/1 (or 1/2) ratio:

1. The *sodium chloride structure* is found in many ionic compounds, including most alkali [Group 1A(1)] halides and hydrides, alkaline earth [Group 2A(2)] oxides and sulfides, and several transition metal oxides and sulfides. To visualize this structure, imagine  $\text{Cl}^-$  anions and  $\text{Na}^+$  cations in separate face-centered cubic arrays. Now picture the two arrays penetrating each other, the smaller  $\text{Na}^+$  ions ending up in the holes between the larger  $\text{Cl}^-$  ions (Figure 12.32A). Thus, each  $\text{Na}^+$  is surrounded by six  $\text{Cl}^-$ , and vice versa (coordination number = 6). Figure 12.32B is a space-filling depiction of the unit cell: four  $\text{Cl}^-$   $[(8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4 \text{ Cl}^-]$  and four  $\text{Na}^+$   $[(12 \times \frac{1}{4}) + 1 \text{ in the center} = 4 \text{ Na}^+]$ , give a 1/1 ion ratio.

**Figure 12.32** The sodium chloride structure. **A**, Expanded view. **B**, Space-filling depiction of the NaCl unit cell.

2. The *zinc blende* ( $ZnS$ ) structure can be pictured as two face-centered cubic arrays, one of  $Zn^{2+}$  ions (*gray*) and the other of  $S^{2-}$  ions (*yellow*), penetrating each other such that each ion is tetrahedrally surrounded by four of the other ions (coordination number = 4) (Figure 12.33). There are four  $[(8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4]$   $S^{2-}$  ions and four  $Zn^{2+}$  ions for a 1/1 ion ratio. Many other compounds, including AgI, CdS, and the copper(I) halides, adopt the zinc blende structure.

**Figure 12.33** The zinc blende structure. **A**, Expanded view (with bonds shown for clarity). **B**, The unit cell is expanded a bit to show interior ions.

3. The *fluorite* ( $CaF_2$ ) structure is common among salts with a 1/2 cation/anion ratio that have relatively large cations and small anions, such as  $SrF_2$  and  $BaCl_2$ . In  $CaF_2$ , the unit cell is a face-centered cubic array of  $Ca^{2+}$  ions with  $F^-$  ions occupying *all* eight available holes (Figure 12.34). This results in a  $Ca^{2+}/F^-$  ratio of 4/8, or 1/2.

**Figure 12.34** The fluorite structure. **A**, Expanded view (with bonds shown for clarity). **B**, The unit cell is expanded a bit to show interior ions.

4. The *antifluorite* structure is common in compounds with a 2/1 cation/anion ratio and a relatively large anion (such as  $K_2S$ ). The ion arrangement is the opposite of that in the fluorite structure: the cations occupy all eight holes formed by the cubic closest packing of the anions.

**Metallic Solids** Most metallic elements crystallize in one of the two closest packed structures (Figure 12.35). In contrast to the weak dispersion forces in atomic solids, powerful metallic bonding forces hold atoms together in **metallic solids**. The properties of metals—high electrical and thermal conductivity, luster, and malleability—result from their delocalized electrons (Section 9.6). Melting points and hardnesses are related to the packing efficiency and number of valence electrons. For example, Group 2A metals are harder and melt higher than Group 1A metals (see Figure 9.28), because the 2A metals have twice as many delocalized valence electrons.

**Network Covalent Solids** Strong covalent bonds link the atoms together in a **network covalent solid**; thus, separate particles are not present. These substances adopt a variety of crystal structures depending on the details of their bonding.

As a consequence of strong bonding, all network covalent solids have extremely high melting and boiling points, but their conductivity and hardness vary. Two examples

Table 12.6

Comparison of the Properties of Diamond and Graphite

Property	Graphite		Diamond	
Density ( $\text{g}/\text{cm}^3$ )	2.27		3.51	
Hardness	<1 (very soft)		10 (hardest)	
Melting point (K)	4100		4100	
Color	Shiny black		Colorless transparent	
Electrical conductivity	High (along sheet)		None	
$\Delta H_{\text{rxn}}^{\circ}$ for combustion (kJ/mol)	-393.5		-395.4	
$\Delta H_{\text{f}}^{\circ}$ (kJ/mol)	0 (standard state)		1.90	

with the same composition but strikingly different properties are the two common crystalline forms of elemental carbon, graphite and diamond:

- *Graphite* occurs as stacked flat sheets of hexagonal carbon rings with a strong  $\sigma$ -bond framework and delocalized  $\pi$  bonds, reminiscent of benzene; the arrangement looks like chicken wire or honeycomb. Whereas the  $\pi$ -bonding electrons of benzene are delocalized over one ring, those of graphite are delocalized over the entire sheet. Thus, graphite conducts electricity well—it is a common electrode material—but only in the plane of the sheets. The sheets interact via dispersion forces, and impurities, such as  $\text{O}_2$ , between the sheets allow them to slide past each other, which explains why graphite is soft and used as a lubricant.
- *Diamond* adopts a face-centered cubic unit cell, with each C tetrahedrally bonded to four others in an endless array. Throughout the crystal, strong single bonds make diamond the hardest natural substance known. Like most network covalent solids, diamond does not conduct electricity because the bonding electrons are localized.

These properties are compared in Table 12.6.

The most important network covalent solids are the *silicates*, which consist of extended arrays of covalently bonded silicon and oxygen atoms. Quartz ( $\text{SiO}_2$ ) is a common example. We'll discuss silicates, which form the structure of clays, rocks, and many minerals, when we consider the chemistry of silicon in Chapter 14.

**Figure 12.36** Crystalline and amorphous silicon dioxide. **A**, Cristobalite, a crystalline form of silica ( $\text{SiO}_2$ ), shows cubic closest packing. **B**, Quartz glass is amorphous with a generally disordered structure.

## Amorphous Solids

Amorphous solids are noncrystalline. Many have small, somewhat ordered regions interspersed among large disordered regions. Charcoal, rubber, and glass are examples.

The process that forms quartz glass is typical of many amorphous solids. Crystalline quartz ( $\text{SiO}_2$ ), which adopts cubic closest packing, is melted and the viscous liquid is cooled rapidly to prevent it from recrystallizing. The chains of Si and O atoms cannot orient themselves quickly enough, so they solidify in a distorted jumble containing gaps and misaligned rows (Figure 12.36). The absence of regularity confers some properties of a liquid; in fact, glasses are sometimes referred to as *supercooled liquids*.

## Bonding in Solids: Molecular Orbital Band Theory

Chapter 9 introduced a qualitative model of metallic bonding, with metal ions submerged in a “sea” of delocalized valence electrons. Molecular orbital (MO) theory offers a more quantitative, and therefore more useful, model called **band theory**. We'll focus on bonding in metals and the resulting conductivity of metals, metalloids, and nonmetals.

**Formation of Valence and Conduction Bands** Recall from Section 11.3 that when two atoms form a diatomic molecule, their atomic orbitals (AOs) combine to form an equal number of molecular orbitals (MOs). Figure 12.37 shows the formation of MOs in lithium. To form  $\text{Li}_2$ , four valence orbitals (one  $2s$  and three  $2p$ ) of each Li atom combine to form eight MOs, four bonding and four antibonding. The order of MOs shows mixing of the  $2s$  and  $2p$  AOs (Figure 11.21B). Two more Li atoms form  $\text{Li}_4$ , a slightly larger aggregate, with 16 delocalized MOs. As more Li atoms join the cluster, more MOs are created, and their energy levels lie closer and closer together. Extending this process to 7 g (1 mol) of lithium results in  $6 \times 10^{23}$  Li atoms ( $\text{Li}_{N_A}$ ) combining to form an extremely large number ( $4 \times \text{Avogadro's number}$ ) of delocalized MOs. *The energies of the MOs are so close that they form a continuum, or band, of MOs.*

**Figure 12.37** The band of molecular orbitals in lithium metal.

The lower energy MOs are occupied by the  $2s^1$  valence electrons and make up the **valence band**. The empty MOs that are higher in energy make up the **conduction band**. In Li metal, the valence band is derived from the  $2s$  AOs, and the conduction band is derived from  $2s$  and mostly  $2p$  AOs. In  $\text{Li}_2$ , two valence electrons fill the lowest energy bonding MO and leave the antibonding MO empty. In Li metal, 1 mol of valence electrons fills the valence band and leaves the conduction band empty.

**How Band Theory Explains Metallic Properties** The key to understanding the properties of metals is that *the valence and conduction bands are contiguous*, that is, the highest level of one touches the lowest of the other. This means that, given an infinitesimal quantity of energy, electrons jump from the filled valence band to the unfilled conduction band: the electrons are completely delocalized and free to move.

- *Electrical conductivity.* Metals conduct electricity so well because an applied field easily excites the highest energy valence electrons into empty conduction orbitals, allowing them to move through the sample.
- *Luster.* With so many closely spaced levels available, electrons absorb and release photons of many frequencies as they move between the valence and conduction bands.
- *Malleability.* Under an applied force, layers of positive metal ions move past each other, always protected from mutual repulsions by the delocalized electrons.
- *Thermal conductivity.* When a metal wire is heated, the highest energy electrons are excited and their extra energy is transferred as kinetic energy along the wire's length.

**Conductivity of Solids and the Size of the Energy Gap** Like metal atoms, large numbers of nonmetal and metalloid atoms can form bands of MOs. Band theory explains differences in electrical conductivity and the effect of temperature among these three classes of substances in terms of the presence of an energy gap between their valence and conduction bands (Figure 12.38):

1. *Conductors (metals)*. The valence and conduction bands of a **conductor** have *no energy gap* between them, so electrons flow when a tiny electrical potential difference is applied. When the temperature is raised, greater random motion of the atoms hinders electron movement: conductivity *decreases* when a metal is heated.
2. *Semiconductors (metalloids)*. In a **semiconductor**, a *small energy gap* exists between the valence and conduction bands. Thermally excited electrons can cross the gap, allowing a small current to flow: in contrast to a conductor, conductivity *increases* when a semiconductor is heated.
3. *Insulators (nonmetals)*. In an **insulator**, a *large energy gap* exists between the bands: no current is observed even when the substance is heated.

**Figure 12.38** Electrical conductivity in a conductor, semiconductor, and insulator.

Another type of electrical conductivity, called **superconductivity**, has been the focus of intensive research for the past few decades. When metals conduct at ordinary temperatures, moving electrons collide with vibrating atoms; the reduction in their flow appears as resistive heating and represents a loss of energy.

For many years, to conduct with no energy loss—to superconduct—required minimizing atom movement by cooling with liquid helium (bp = 4 K; price ≈ \$11/L). Then, in 1986, certain ionic oxides that superconduct near the boiling point of liquid nitrogen (bp = 77 K; price = \$0.06/L) were prepared. Like metal conductors, oxide superconductors, such as  $\text{YBa}_2\text{Cu}_3\text{O}_7$ , have no gap between bands. In 1989, oxides with Bi and Tl instead of Y and Ba were synthesized and found to superconduct at 125 K; and in 1993, an oxide with Hg, Ba, and Ca, in addition to Cu and O, superconducted at 133 K. Such materials could transmit electricity with no loss of energy, allowing power plants to be located far from cities. They could be part of ultrasmall microchips for ultrafast computers, electromagnets to levitate superfast trains, and inexpensive medical diagnostic equipment with superb image clarity. However, the oxides are brittle and not easy to machine, and when warmed, the superconductivity may disappear and not return on cooling. Addressing these and related problems will involve chemists, physicists, and engineers for many years.

### › Summary of Section 12.6

- › Particles in crystalline solids lie at points that form a structure of repeating unit cells.
- › The three types of unit cells of the cubic system are simple, body-centered, and face-centered. The highest packing efficiency occurs with cubic (face-centered) and hexagonal closest packing.

- › Bond angles and distances in a crystal are determined with x-ray diffraction analysis and scanning tunneling microscopy. These data are used to determine atomic radii.
- › Atomic solids [Group 8A(18)] adopt cubic closest packing, with atoms held together by weak dispersion forces.
- › Molecular solids have molecules at the lattice points and often adopt cubic closest packing. Combinations of intermolecular forces (dispersion, dipole-dipole, and H bonding) result in physical properties that vary greatly.
- › Ionic solids crystallize with one ion filling holes in the cubic closest packed array of the other. High melting points and hardness and low conductivity arise from strong ionic attractions.
- › Most metals have a closest packed structure. Their physical properties result from the high packing efficiency and the presence of delocalized electrons.
- › Atoms of network covalent solids are covalently bonded throughout the sample, so these substances have very high melting and boiling points.
- › Amorphous solids have little regularity in their structure.
- › Band theory proposes that atomic orbitals of many atoms combine to form a continuum, or band, of molecular orbitals. Metals are electrical conductors because electrons move freely from the filled (valence) band to the empty (conduction) band. Insulators have a large energy gap between the two portions, and semiconductors have a small gap, which can be bridged by heating.

## 12.7 ADVANCED MATERIALS

In the last few decades, the exciting field of materials science has applied concepts from solid-state chemistry, physics, and engineering. Objects that were once considered futuristic fantasies have become realities: powerful, ultrafast computers smaller than a cell phone; cars powered by sunlight and made of nonmetallic parts stronger than steel and lighter than aluminum; ultrasmall machines constructed by manipulating individual atoms and molecules. In this section, we briefly discuss some of these remarkable materials.

### Electronic Materials

The ideal of a perfectly ordered crystal is attainable only if the crystal is grown very slowly under carefully controlled conditions. When crystals form more rapidly, **crystal defects** inevitably result. Planes of particles are misaligned, particles are out of place or missing entirely, and foreign particles replace those that belong in the lattice. Although defects usually weaken a substance, they can be introduced intentionally to improve materials, giving them increased strength, hardness, or conductivity. Centuries of metal-working exemplify the traditional importance of crystal defects, which is the basis of modern electronic materials.

**Introducing Crystal Defects in Welding and Alloying** In the process of *welding* two metals together, *vacancies* form near the surface when atoms vaporize, and then these vacancies move deeper as atoms from lower rows rise to fill the gaps. Welding causes the two types of metal atoms to intermingle and fill each other's vacancies. Metal *alloying* introduces several kinds of crystal defects, as when some atoms of a second metal occupy lattice sites of the first. Often, the alloy is harder than the pure metal; an example is brass, an alloy of copper with zinc. One reason the welded metals are stronger and the alloy is harder is that the second metal contributes additional valence electrons for metallic bonding.

**Doped Semiconductors** By controlling the number of valence electrons through the creation of specific types of crystal defects, chemists and engineers can greatly increase the conductivity of a semiconductor. For example, pure silicon [Si; Group 4A(14)], conducts poorly at room temperature because an energy gap separates its filled valence band from its conduction band (Figure 12.39A). Silicon's conductivity

**Figure 12.39** Crystal structures and band representations of doped semiconductors. **A**, Pure silicon has an energy gap between its valence and conduction bands, which keeps conductivity low at room temperature. **B**, Doping silicon with phosphorus (*purple*) adds additional valence electrons. **C**, Doping silicon with gallium (*orange*) removes electrons from the valence band and introduces positive holes.

can be greatly enhanced by **doping**, adding small amounts of other elements to increase or decrease the number of valence electrons in the bands.

- *Doping to create an n-type semiconductor: increasing the number of valence electrons.* When Si is doped with phosphorus [or another Group 5A(15) element], P atoms occupy some of the lattice sites. Since P has one more valence electron than Si, this additional electron must enter an empty orbital in the conduction band, thus bridging the energy gap and increasing conductivity. Such doping creates an *n-type semiconductor*, so called because extra *negative* charges (electrons) are present (Figure 12.39B).
- *Doping to create a p-type semiconductor: decreasing the number of valence electrons.* When Si is doped with gallium [or another Group 3A(13) element], Ga atoms occupy some sites (Figure 12.39C). Since Ga has one fewer valence electron than Si, some of the orbitals in the valence band are empty, which creates a positive site. Si electrons can migrate to these empty orbitals, thereby increasing conductivity. Such doping creates a *p-type semiconductor*, so called because the empty orbitals act as *positive holes*.

In contact with each other, an n-type and a p-type semiconductor form a *p-n junction*. When the negative terminal of a battery is connected to the n-type portion and the positive terminal to the p-type portion, electrons (*yellow, negative spheres*) flow freely in the n-to-p direction, which has the simultaneous effect of moving holes (*white, positive spheres*) in the p-to-n direction (Figure 12.40A). No current flows if the terminals are reversed (Figure 12.40B). Such unidirectional current flow makes a p-n junction act as a *rectifier*, a device that converts alternating current into direct current. A p-n junction in a modern integrated circuit can be made smaller than a square 10  $\mu\text{m}$  on a side.

A modern computer chip the size of a nickel may incorporate millions of p-n junctions in the form of *transistors*. One of the most common types, an n-p-n transistor, is made by sandwiching a p-type portion between two n-type portions to form adjacent p-n junctions. The current flowing through one junction controls the current flowing through the other and results in an amplified signal.

**Figure 12.40** The p-n junction. Placing a p-type semiconductor adjacent to an n-type creates a p-n junction.

One of the more common types of *solar cell* is, in essence, a p-n junction with an n-type surface exposed to a light source. Light provides the energy to free electrons from the n-type region and accelerate them through an external circuit into the p-type region, thus producing a current.

## Liquid Crystals

Incorporated in the membrane of every cell in your body and in the display of every electronic device are **liquid crystals**. These materials flow like liquids but, like crystalline solids, pack with a high degree of order at the molecular level.

**Ordering of the Particles** Let's examine how particles are ordered in the three physical states and how this affects their properties. Both gases and liquids are *isotropic*—their physical properties are the same in every direction within the phase. For example, the viscosity of a gas or a liquid is the same regardless of direction. Glasses and other amorphous solids are also isotropic because they have no regular lattice structure.

In contrast, crystalline solids have a high degree of order among their particles. The properties of a crystal *do* depend on direction, so a crystal is *anisotropic*. The facets in a cut diamond, for instance, arise because the crystal cracks in one direction more easily than in another. Liquid crystals are anisotropic with respect to several physical properties, including electrical and optical properties, which differ with direction through the phase.

**Molecular Characteristics** Liquid crystal phases consist of individual molecules with two characteristics: (1) a long, cylindrical shape and (2) a structure that fosters intermolecular attractions but inhibits perfect crystalline packing. Molecules that form liquid crystal phases have rodlike shapes and certain groups—in the cases shown in Figure 12.41, flat, benzene-like ring systems—that keep the molecules extended. Many of these molecules also have polarity associated with the long molecular axis. A strong electric field can orient these polar molecules like compass needles in a magnetic field.

The viscosity of a liquid crystal phase is lowest in the direction parallel to the long axis. Like moistened microscope slides, it is easier for the molecules to slide

**Figure 12.41** Structures of two typical molecules that form liquid crystal phases. Note the long, extended shapes and the regions of high (*red*) and low (*blue*) electron density.

along each other (because the total attractive force remains the same), than it is for them to pull apart from each other sideways. As a result, the molecules tend to align while the phase flows.

**Controlling Conditions to Form Phases** Liquid crystal phases can arise in two general ways, and, sometimes, either way can occur in the same substance:

1. *Thermotropic phases* develop as a result of a change in temperature. As a crystalline solid is heated, the molecules leave their lattice sites, but the intermolecular interactions are still strong enough to keep the molecules aligned with each other along their long axes. Like any other phase, the liquid crystal phase has sharp transition temperatures, but they occur over a relatively small temperature range. Further heating provides enough kinetic energy for the molecules to become disordered, as in a normal liquid. The typical range for liquid crystal phases of pure substances is from  $<1^{\circ}\text{C}$  to as much as  $10^{\circ}\text{C}$ , but mixing phases of two or more substances can greatly extend this range. For this reason, the liquid crystal phases used within display devices, as well as those within cell membranes, consist of mixtures of molecules.

2. *Lyotropic phases* occur in solution as the result of changes in concentration, but the conditions for forming such a phase vary for different substances. For example, when purified, some biomolecules that exist in cell membranes form lyotropic phases in water at the temperature that occurs within the organism. At the other extreme, Kevlar, a fiber used in bulletproof vests and high-performance sports equipment, forms a lyotropic phase in concentrated  $\text{H}_2\text{SO}_4$  solution.

In some cases, a substance that forms a given liquid crystal phase under one set of conditions forms other phases under different conditions. Thus, a given thermotropic liquid crystal substance can pass from disordered liquid through a series of distinct liquid crystal phases to an ordered crystal through a decrease in temperature. A lyotropic substance can undergo similar changes through an increase in concentration.

**Types of Order in Liquid Crystal Phases** Molecules that form liquid crystal phases can exhibit various types of order. Three common types are nematic, cholesteric, and smectic:

1. In a *nematic phase*, the molecules lie in the same direction but their ends are not aligned, much like a school of fish swimming in synchrony (Figure 12.42A). The nematic phase is the least ordered type of liquid crystal phases.
2. In a *cholesteric phase*, which is somewhat more ordered, the molecules lie in layers that each exhibit nematic-type ordering. Rather than lying in parallel fashion, however, each layer is rotated by a fixed angle with respect to the next layer to give a helical (corkscrew) arrangement. A cholesteric phase is often called a *twisted nematic phase* (Figure 12.42B).

**Figure 12.42** The three common types of ordering in liquid crystal phases.

**Figure 12.43** Liquid crystal-type phases in biological systems. **A**, Nematic arrays of tobacco mosaic virus particles within the fluid of a tobacco leaf. **B**, The smectic-like arrangement of actin and myosin protein filaments in voluntary muscle cells.

Source: (A) © J. R. Factor/Science Source (B) © C. F. Armstrong/Science Source

3. In a *smectic phase*, which is the most ordered, the molecules lie parallel to each other, *with their ends aligned*, in layers that are stacked directly over each other (Figure 12.42C). The long molecular axis has a well-defined angle (shown in the figure as  $90^\circ$ ) with respect to the plane of the layer. The molecules in Figure 12.41 form nematic or smectic phases. Liquid crystal-type phases appear in many biological systems (Figure 12.43).

**Applications of Liquid Crystals** The ability to control the orientation of the molecules in a liquid crystal allows us to produce materials with high strength or unique optical properties:

1. *High-strength applications* involve the use of extremely long molecules called *polymers*. While in a thermotropic liquid crystal phase and during their flow through the processing equipment, these molecules become highly aligned, like the fibers in wood. Cooling solidifies them into fibers, rods, and sheets that can be shaped into materials with superior mechanical properties. Sporting equipment, supersonic aircraft parts, and the sails used in the America’s Cup races are fabricated from these polymeric materials. (We discuss the structure and physical behavior of polymers later in this section and their synthesis in Chapter 15.)

2. *Optical applications* include the liquid crystal displays (LCDs) used in countless devices, such as watches, calculators, cell phones, and tablets. All depend on *changes in molecular orientation in an electric field*. Figure 12.44 shows a small portion of a wristwatch LCD. Layers of nematic phases are sandwiched between thin glass plates that incorporate transparent electrodes. The long molecular axes lie parallel to the plane of the plates. The distance between plates (6–8  $\mu\text{m}$ ) allows the molecular axes within each succeeding layer to twist just enough for the molecular orientation at the bottom plate to be  $90^\circ$  from that at the top plate. Above and below this “sandwich” are thin polarizing filters that allow light waves oriented in only one direction to pass through. The filters are placed in a “crossed” arrangement, so that light passing through the top filter must twist  $90^\circ$  to pass through the bottom filter. This whole grouping of filters, plates, and liquid crystal phase lies on a mirror.

A current generated by the watch battery controls the orientation of the molecules. With the current on in one region of the display, the molecules become oriented *toward* the field, and thus block the light from passing through to the bottom filter, so that region appears dark. With the current off in another region, light passes through the molecules and bottom filter to the mirror and back again, so that region appears bright.

Cholesteric liquid crystals are used in applications that involve color changes with temperature. The twisted molecular orientation “unwinds” with heating, and the extent of the unwinding determines the color. Liquid crystal thermometers include a mixture of substances to widen their range of temperatures. Newer uses include “mapping” the area of a tumor, detecting faulty connections in electronic circuit boards, and nondestructive testing of materials under stress.

**Figure 12.44** A liquid crystal display (LCD). A close-up of the “2” on a wristwatch LCD reveals two polarizers sandwiching two glass plates, which sandwich a liquid crystal (LC) layer, all lying on a mirror. When light waves enter the first polarizer, waves oriented in one direction emerge to enter the LC layer. Enlarging a dark region (*top blow-up*) shows the LC molecules aligned, keeping light waves from passing through; thus, the viewer sees no light. Enlarging a bright region (*bottom blow-up*) shows the LC molecules rotating the plane of the light waves, which can then pass through and reach the viewer.

## Ceramic Materials

First developed by Stone Age people, **ceramics** are nonmetallic, nonpolymeric solids hardened by high temperature. Clay ceramics consist of silicate microcrystals suspended in a glassy cementing medium. In “firing” a ceramic pot, for example, a kiln heats the object, made of an aluminosilicate clay, such as kaolinite, to 1500°C and the clay loses water:

During the heating process, the structure rearranges to an extended network of Si-centered and Al-centered tetrahedra of O atoms (Section 14.6).

Bricks, porcelain, glazes, and other clay ceramics are hard and resistant to heat and chemicals. Today’s high-tech ceramics have these characteristics in addition to superior electrical and magnetic properties (Table 12.7). As just one example, consider the unusual electrical behavior of certain zinc oxide (ZnO) composites. Ordinarily a semiconductor, ZnO can be doped so that it becomes a conductor. Imbedding particles of the doped oxide into an insulating ceramic produces a variable resistor: at low voltage, the material conducts poorly, but at high voltage, it conducts well. The changeover voltage can be “preset” by controlling the size of the ZnO particles and the thickness of the insulating medium.

**Table 12.7**
**Some Uses of Modern Ceramics and Ceramic Mixtures**

Ceramic	Applications
SiC, Si <sub>3</sub> N <sub>4</sub> , TiB <sub>2</sub> , Al <sub>2</sub> O <sub>3</sub>	Whiskers (fibers) to strengthen Al and other ceramics
Si <sub>3</sub> N <sub>4</sub>	Car engine parts; turbine rotors for “turbo” cars; electronic sensor units
Si <sub>3</sub> N <sub>4</sub> , BN, Al <sub>2</sub> O <sub>3</sub>	Support or layering materials (as insulators) in electronic microchips
SiC, Si <sub>3</sub> N <sub>4</sub> , TiB <sub>2</sub> , ZrO <sub>2</sub> , Al <sub>2</sub> O <sub>3</sub> , BN	Cutting tools, edge sharpeners (as coatings and whole devices), scissors, surgical tools, industrial “diamond”
BN, SiC	Armor-plating reinforcement fibers (as in Kevlar composites)
ZrO <sub>2</sub> , Al <sub>2</sub> O <sub>3</sub>	Surgical implants (hip and knee joints)

**Preparing Modern Ceramics** Among the important modern ceramics are silicon carbide (SiC) and nitride (Si<sub>3</sub>N<sub>4</sub>), boron nitride (BN), and the superconducting oxides. They are prepared by standard chemical methods that involve driving off a volatile component during the reaction:

1. *SiC ceramics* are made from compounds used in silicone polymer manufacture (we’ll discuss these polymers in Section 14.6):

This product is heated to 800°C to form the ceramic:

Silicon carbide can also be prepared by the direct reaction of silicon and graphite under vacuum:

The nitride is also prepared by reaction of the elements:

2. *BN ceramics* are produced through the reaction of boron trichloride or boric acid with ammonia:

Heat drives off some of the bound nitrogen as NH<sub>3</sub> to yield the ceramic:

3. One type of *superconducting oxide* is made by heating a mixture of barium carbonate with copper and yttrium oxides, followed by further heating in the presence of  $O_2$ :

**Ceramic Structures and Uses** Structures of several ceramic materials are shown in Figure 12.45.

1. *Silicon carbide* has a diamond-like structure (Figure 12.45A). Network covalent bonding gives this material great strength. It is made into thin fibers, called *whiskers*, to reinforce other ceramics and prevent cracking in a composite structure, much like steel rods reinforcing concrete.

2. *Silicon nitride* is virtually inert chemically, retains its strength and wear resistance for extended periods above  $1000^\circ C$ , is dense and hard, and acts as an electrical insulator. Many automakers are testing it in high-efficiency car and truck engines because of its low weight, tolerance of high operating temperatures, and little need for lubrication.

3. *BN ceramics* exist in two structures, analogous to the common crystalline forms of carbon. In the graphite-like form, BN has extraordinary properties as an electrical insulator. At high temperature and very high pressure ( $1800^\circ C$  and  $8.5 \times 10^4$  atm), BN converts to a diamond-like structure (Figure 12.45B), which is extremely hard and durable. Both forms are virtually invisible to radar.

4. *Superconducting oxides* often contain copper in an unusual oxidation state. In  $YBa_2Cu_3O_7$  (Figure 12.45C), for instance, assuming oxidation states of +3 for Y, +2 for Ba, and  $-2$  for O, the three Cu atoms have a total oxidation state of +7. This is allocated as  $Cu(II)_2Cu(III)$ , with one Cu in the unusual +3 state. X-ray diffraction analysis indicates that a distortion in the structure makes four of the oxide ions unusually close to the  $Y^{3+}$  ion, which aligns the Cu ions into chains within the crystal. It is thought that a specific half-filled  $3d$  orbital in Cu oriented toward a neighboring  $O^{2-}$  ion may be associated with superconductivity.

Because of brittleness, it is difficult to fashion these ceramics into wires, but methods for making films and ribbons have been developed. The brittleness arises from the strength of the ionic-covalent bonding and the resulting inability to deform. Under stress, a microfine defect widens until the material cracks. One new method forms defect-free superconducting oxide ceramics using controlled packing and heat treatment of extremely small, uniform oxide particles coated with organic polymers. Another method is aimed at arresting a widening crack. The ceramics are embedded with zirconia ( $ZrO_2$ ), whose crystal structure expands up to 5% under mechanical stress. When an advancing crack reaches them, the zirconia particles pinch it shut. A third method prepares precisely grown crystals of  $Al_2O_3$  and  $GdAlO_3$ , which become entangled during the solidification process. The resulting material bends without cracking above 1800 K.

## Polymeric Materials

A **polymer** (Greek, “many parts”) is an extremely large molecule, or **macromolecule**, consisting of a covalently linked chain of smaller molecules, called **monomers** (Greek, “one part”). The monomer is the *repeat unit* of the polymer, and a polymer may have hundreds to hundreds of thousands of repeat units. Many types of monomers give polymers the complete repertoire of intermolecular forces.

- *Synthetic* polymers are created in the laboratory.
- *Natural* polymers (or *biopolymers*) are created within organisms.

In this section, we examine the physical nature of synthetic polymers and explore the role of intermolecular forces in their properties and uses. In Chapter 15, we’ll examine the types of monomers, the preparation of synthetic polymers, and the monomers, structures, and functions of some biopolymers.

**Dimensions of a Polymer Chain** Polymers differ from smaller molecules in terms of molar mass, chain length, shape, and size. We’ll discuss these, using polyethylene, by far the most common synthetic polymer, as an example.

1. *Polymer mass.* The molar mass of a polymer chain ( $\mathcal{M}_{\text{polymer}}$  in g/mol, often referred to as the *molecular weight*) depends on the molar mass of the repeat unit ( $\mathcal{M}_{\text{repeat}}$ ) and the **degree of polymerization** ( $n$ ), the number of repeat units in the chain:

$$\mathcal{M}_{\text{polymer}} = \mathcal{M}_{\text{repeat}} \times n$$

For example, the molar mass of the ethylene repeat unit ( $-\text{CH}_2-\text{CH}_2-$ ) is 28 g/mol. If an individual polyethylene chain in a plastic grocery bag has a degree of polymerization of 7100, the molar mass of that chain is

$$\mathcal{M}_{\text{polymer}} = \mathcal{M}_{\text{repeat}} \times n = (28 \text{ g/mol}) (7.1 \times 10^3) = 2.0 \times 10^5 \text{ g/mol}$$

Table 12.8 shows some other examples.

**Table 12.8**

**Molar Masses of Some Common Polymers**

Name	$\mathcal{M}_{\text{polymer}}$ (g/mol)	$n$	Uses
Acrylates	$2 \times 10^5$	$2 \times 10^3$	Rugs, carpets
Polyamide (nylons)	$1.5 \times 10^4$	$1.2 \times 10^2$	Tires, fishing line
Polycarbonate	$1 \times 10^5$	$4 \times 10^2$	Compact discs
Polyethylene	$3 \times 10^5$	$1 \times 10^4$	Grocery bags
Polyethylene (ultrahigh molecular weight)	$5 \times 10^6$	$2 \times 10^5$	Hip joints
Poly(ethylene terephthalate)	$2 \times 10^4$	$1 \times 10^2$	Soda bottles
Polystyrene	$3 \times 10^5$	$3 \times 10^3$	Packing, coffee cups
Poly(vinyl chloride)	$1 \times 10^5$	$1.5 \times 10^3$	Plumbing

However, even though the monomer repeat unit in any given chain has the same molar mass, the degree of polymerization often varies considerably from chain to chain. Thus, *a sample of a synthetic polymer has a distribution of chain lengths and molar masses*. Polymer chemists use various definitions of the *average* molar mass, and a common one is the *number-average molar mass*,  $\mathcal{M}_n$ :

$$\mathcal{M}_n = \frac{\text{total mass of all chains}}{\text{number of moles of chains}}$$

If the number-average molar mass of the polyethylene in grocery bags is, for example,  $1.6 \times 10^5$  g/mol, the chains may vary in molar mass from about  $7.0 \times 10^4$  to  $3.0 \times 10^5$  g/mol.

2. *Polymer chain length.* The long axis of a polymer chain is called its *backbone*. The length of an *extended* backbone is simply the number of repeat units (degree of polymerization,  $n$ ) times the length of each repeat unit ( $l_0$ ). For instance, the length

of an ethylene repeat unit is about 250 pm, so the extended length of our grocery-bag polyethylene chain is

$$\text{Length of extended chain} = n \times l_0 = (7.1 \times 10^3) (2.5 \times 10^2 \text{ pm}) = 1.8 \times 10^6 \text{ pm}$$

Comparing this length with the thickness of the chain, which is about 40 pm, shows the threadlike nature of the extended chain (length about 50,000 times width).

3. *Coiled shape and size.* A polymer molecule, however, whether pure or in solution, doesn't exist as an extended chain. In principle, the shape of the molecule arises from free rotation around all the single bonds. Thus, as each repeat unit rotates randomly, the chain continuously changes direction, turning back on itself many times and eventually arriving at the **random coil** shape that most polymers adopt (Figure 12.46). In reality, rotation is not completely free because intermolecular forces between chain portions, between different chains, and/or between chain and solvent have significant effects on the actual shape of a polymer chain.

The size of the coiled chain is expressed by its **radius of gyration,  $R_g$** , the average distance from the center of mass of the molecule to the outer edge of the coil (Figure 12.46). Even though  $R_g$  is reported as a single value for a given polymer, it represents an average value for many chains. The mathematical expression for the radius of gyration includes the length of each repeat unit and the degree of polymerization:\*

$$R_g = \sqrt{\frac{nl_0^2}{6}}$$

As expected, the radius of gyration increases with the degree of polymerization, and thus with the molar mass as well. Light-scattering measurements correlate with these calculated results, so for many polymers the radius of gyration can be determined experimentally.

\*The mathematical derivation of  $R_g$  is beyond the scope of this text, but it is analogous to the two-dimensional "walk of the drunken sailor." With each step, the sailor stumbles in random directions and, given enough time, ends up very close to the starting position. The radius of gyration quantifies how far the end of the polymer chain (the sailor) has gone from the origin.

**Figure 12.46** The random-coil shape of a polymer chain. Note the random coiling of the chain's carbon atoms (black). Sections of several nearby chains (red, green, and yellow) are entangled with this chain, kept near one another by dispersion forces. In reality, entangling chains fill any gaps shown here.

For our grocery-bag polyethylene chain, we have

$$R_g = \sqrt{\frac{nl_0^2}{6}} = \sqrt{\frac{(7.1 \times 10^3)(2.5 \times 10^2 \text{ pm})^2}{6}} = 8.6 \times 10^3 \text{ pm}$$

Doubling the radius gives a diameter of  $1.7 \times 10^4$  pm for the coiled chain, less than one-hundredth the length of the extended chain!

**Polymer Crystallinity** A sample of a given polymer is not just a disorderly jumble of chains. If the molecular structure allows neighboring chains to pack together and if the chemical groups lead to favorable dipole-dipole, H bonding, and/or dispersion forces, portions of the chains can align regularly and exhibit crystallinity.

However, the crystallinity of a polymer is very different from the crystal structures we discussed earlier. In those structures, the orderly array extends over many atoms or molecules, and the unit cell includes at least one atom or molecule. In contrast, the orderly regions of a polymer rarely involve even one whole molecule (Figure 12.47). At best, a polymer is *semicrystalline*, because parts of the molecule align with parts of neighboring molecules (or with other parts of the same chain), while most of the chain remains as a random coil.

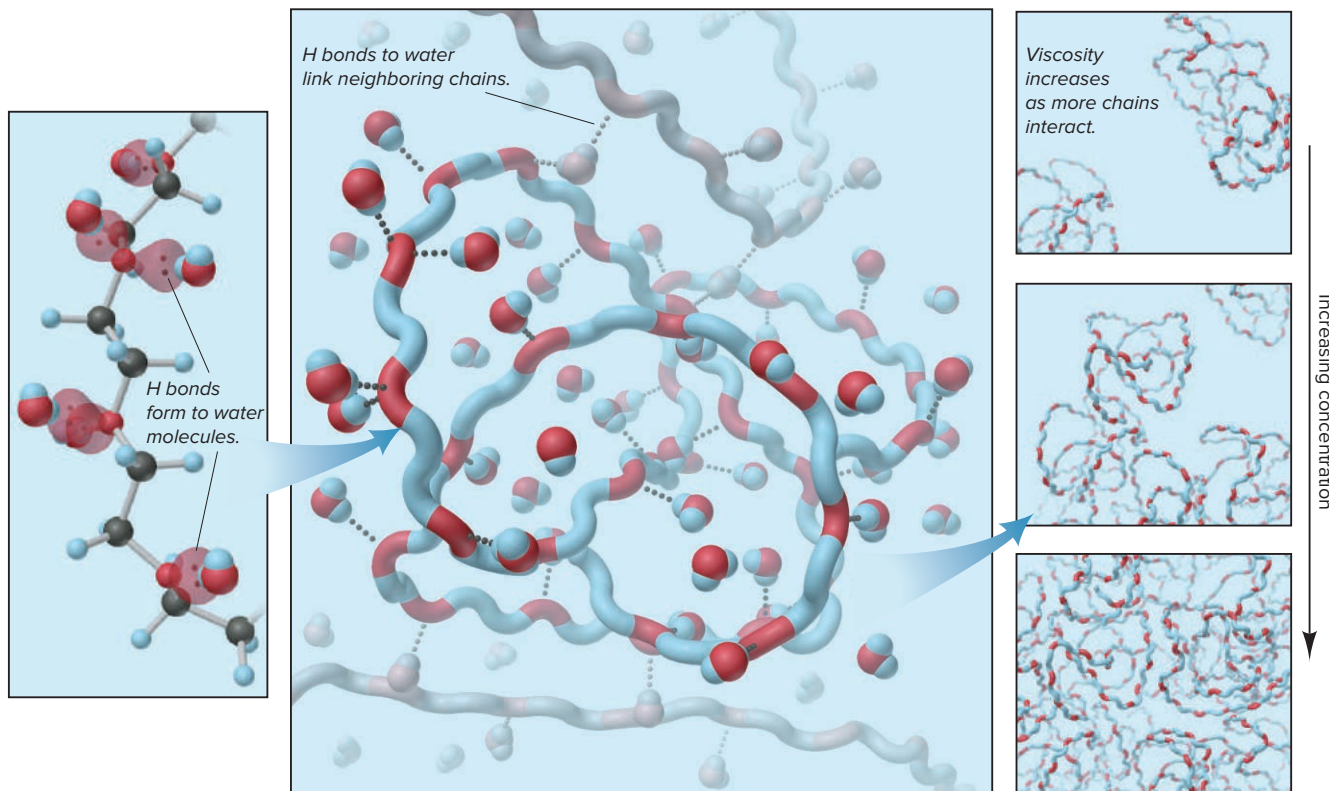

**Figure 12.47** The semi-crystallinity of a polymer chain. Several crystalline regions (*darker color*) have randomly coiled regions between them. Crystalline regions from nearby chains (*red and yellow*) align with those in the main chain.

**Viscosity of Pure and Dissolved Polymers** Some of the most important uses of polymers arise from their ability to change the viscosity of a solvent in which they are dissolved and to undergo temperature-dependent changes in their own viscosity.

1. *Dissolved polymers.* When an appreciable amount of polymer (approximately 5–15 mass %) dissolves, the viscosity of the solution is much higher than that of the pure solvent. In fact, polymers are added to increase the viscosity of many common materials, such as motor oil, paint, and salad dressing. As the random coil of a polymer moves through a solution, solvent molecules are attracted to it through intermolecular forces (Figure 12.48). Thus, as the solution flows, the polymer coil drags along solvent molecules that are interacting with other solvent molecules and other coils, and flow is reduced. Increasing the polymer concentration increases the viscosity because coils are more likely to become entangled.

Viscosity is a property of a particular polymer-solvent pair at a given temperature. The size (radius of gyration) of a random coil in solution increases with molar mass, and so does the viscosity. To improve polymer manufacture, chemists have developed

**Figure 12.48** The viscosity of a polymer in aqueous solution. A section of a poly(ethylene oxide) chain (*left panel*) forms H bonds between the lone pairs of the chain's O atoms and the H atoms of water molecules. A polymer chain (*blue and red coiled rod, center panel*) forms many H bonds with water molecules that allow the chain to interact with other chains. As the concentration of polymer increases (*three right panels*), the viscosity of the solution increases.

equations to predict the viscosity of polymers of different molar masses in a variety of solvents (see Problem 12.147).

2. *Pure polymers.* Intermolecular forces also play a major role in the flow of a pure polymer. At temperatures high enough to melt them, many polymers exist as viscous liquids, flowing more like honey than water. The forces between the chains, as well as the entangling of chains, hinder the flow. As the temperature decreases, the intermolecular attractions exert a greater effect, and the eventual result is a rigid solid. If the chains don't crystallize, the resulting material is called a *polymer glass*. The transition from a liquid to a glass occurs over a narrow temperature range (10–20°C) for a given polymer; the temperature at the midpoint of the range is called the *glass transition temperature*,  $T_g$ . Like window glass, many polymer glasses are transparent, including polystyrene in drinking cups and polycarbonate in eyeglass lenses.

**Plasticity of Polymers** The flow-related properties of polymers give rise to their familiar **plastic** mechanical behavior. The word *plastic* refers to a material that, when deformed, retains its new shape; in contrast, when an *elastic* object is deformed, it returns to its original shape. Many polymers can be deformed (stretched, bent, twisted) when warm and retain their deformed shape when cooled. In this way, they are made into milk bottles, car parts, and countless other everyday objects.

**Molecular Architecture of Polymers** A polymer's architecture—its overall spatial layout and molecular structure—is crucial to its properties. In addition to linear chains, more complex architectures arise through branching and crosslinking:

1. **Branches** are smaller chains appended to a polymer backbone. As the number of branches increases, the chains cannot pack as well, so the degree of crystallinity

decreases and the polymer is less rigid. A small amount of branching occurs as a side reaction in the preparation of high-density polyethylene (HDPE). It is still largely linear and rigid enough for use in milk containers. In contrast, much more branching is intentionally induced to prepare low-density polyethylene (LDPE). The chains cannot pack well, so crystallinity is low. This polymer is used in flexible, transparent food storage bags.

*Dendrimers* are prepared from monomers with three or more attachment points, so each monomer forms branches. In essence, then, dendrimers have no backbone and consist only of branches. As a dendrimer grows, it has a constantly increasing number of branches and an incredibly large number of end groups at its outer edge. Chemists use dendrimers to bind one polymer to another to create films and fibers and to deliver drugs in medical applications.

Bicycle helmet containing a thermoset polymer.

Source: © Ingram Publishing/Alamy RF

2. **Crosslinks** can be thought of as branches that link one chain to another. The extent of crosslinking leads to remarkable differences in properties. A small degree of crosslinking often yields a *thermoplastic* polymer, one that still flows at high temperatures. But, as the extent of crosslinking increases, a thermoplastic polymer is transformed into a *thermoset* polymer, one that can no longer flow because it has become a single network. Below their glass transition temperatures, some thermosets are extremely rigid and strong, making them ideal as matrix materials in high-strength composites (*see photo*).

Above their glass transition temperatures, many thermosets become **elastomers**, polymers that can be stretched and immediately spring back to their initial shapes when released, like a trampoline or a rubber band. When you stretch a rubber band, individual polymer chains flow for only a short distance before the connectivity of the network returns them to their original positions. Table 12.9 is a list of some elastomers.

Table 12.9

Some Common Elastomers

Name	$T_g$ (°C)	Uses
Poly(dimethyl siloxane)	-123	Breast implants
Polybutadiene	-106	Rubber bands
Polyisoprene	-65	Surgical gloves
Polychloroprene (neoprene)	-43	Footwear; medical tubing

**Impact of Monomer Sequence** Differences in monomer sequences influence polymer properties as well. A *homopolymer* consists of one type of monomer (A—A—A—A—A—...), whereas a **copolymer** consists of two or more types. The simplest copolymer is called an *AB block copolymer* because a chain (block) of monomer A and a chain of monomer B are linked at one point:

If the intermolecular forces between the A and B portions of the chain are weaker than those between different regions within each portion, the A and B portions form their own random coils. This ability makes AB block copolymers ideal *adhesives* for joining two polymer surfaces covalently. An ABA block copolymer has A chains linked at each end of a B chain:

Some of these block copolymers act as *thermoplastic elastomers*, materials shaped at high temperature that become elastomers at room temperature; many are used in the modern footwear industry.

Silicone polymers are described in Chapter 14, and organic reactions that form polymer chains from monomers are examined in Chapter 15.

## Nanotechnology: Designing Materials Atom by Atom

**Nanotechnology** is the science and engineering of nanoscale systems, whose sizes range from 1 to 100 nm. (Recall that 1 nm is  $10^{-9}$  m—about one-billionth the width of your dorm-room desk or one-millionth the width of your pen tip. A nanometer is to a meter as a marble is to Earth!) Nanotechnology joins scientists from physics, materials science, chemistry, biology, environmental science, medicine, and many branches of engineering.

Nanoscale materials behave neither like atoms, which are smaller (about  $1 \times 10^1$  nm), nor like crystals, which are larger (at least  $1 \times 10^5$  nm). The different behavior is due to a surface area that is similar to their interior volume—for example, a 5-nm particle has about half of its atoms on its surface. Cut a piece of ordinary aluminum foil into pieces just large enough to see with a light microscope and they still behave like the original piece. But, if you could cut the original piece into 20–30-nm pieces, they would explode. Indeed, aluminum nanoparticles are used in fireworks and propellants.

As so often happens in science, a technological advance allowed this new field to blossom. Nanotechnologists can use the scanning tunneling microscope (see Tools of the Laboratory in Section 12.6) and the similar scanning probe and atomic force microscopes to examine the chemical and physical properties of nanostructures and build them up, in many cases, atom by atom.

Two features of nanoscale engineering occur routinely in nature:

1. *Self-assembly* is the ability of smaller, simpler parts to organize themselves into a larger, more complex whole. On the molecular scale, self-assembly refers to atoms or small molecules aggregating through intermolecular forces. Oppositely charged regions on two such particles make contact to form a larger particle, which in turn aggregates with another to form a still larger one.
2. *Controlled orientation* is the positioning of two molecules near each other long enough for intermolecular forces to result in a change, often a bond breaking or forming. All enzymes function this way.

Because this field is changing so fast, we can only provide a glimpse of a few exciting research directions in nanotechnology.

**Nanoscale Optical Materials** *Quantum dots* are nanoparticles of a semiconducting material, such as gallium arsenide (GaAs) or gallium selenide (GaSe), that are smaller than 10 nm. Rather than having a band of energy levels, the dot has discrete energy levels, much like a single atom. As in atoms, the energy levels can be studied with spectroscopy; unlike atoms, quantum dots can be modified chemically. When high-energy (short-wavelength) UV light irradiates a suspension of quantum dots, they become excited and emit radiation of lower energy (longer wavelength). Most importantly, the emitted wavelengths depend on the size of the dots: the larger the particles, the longer the wavelength emitted. Thus, the color of the emitted light can be “tuned” by varying the dimensions of the nanoparticles (Figure 12.49). One use for quantum dots is the imaging of specific cells. The dot is encapsulated in a coating and then bonded to a particular protein used by a target organ. The cells in the target incorporate the protein, along with its attached quantum dot, and the location of the protein is viewed spectroscopically.

**Nanostructured Materials** *Nanostructuring*, the construction of bulk materials from nanoscale building blocks, increases strength, ductility, plasticity, and many other properties. The resulting *nanocomposites* behave as liquid magnets, ductile cements, conducting elastomers, and many other unique materials.

One example mimics a familiar natural material. Bones are natural nanocomposites of hydroxyapatite (a type of calcium phosphate) and other minerals. Synthetic nanocrystalline hydroxyapatite has weight-bearing properties identical to bone and can be formed into a framework into which natural bone tissue can grow to heal a fracture. Another material, called a *ferrofluid*, consists of magnetic nanoparticles (usually

**Figure 12.49** The colors of quantum dots. The smaller the dots, the shorter the emitted wavelengths.

magnetite,  $\text{Fe}_3\text{O}_4$ ) dispersed in a viscous fluid. When placed in a magnetic field, the particles align to conform to the shape of the field (Figure 12.50). Ferrofluids find uses in automobile shock absorbers, magnetic plastics, audio speakers, computer hard drives, high-vacuum valves, and many other devices.

**High-Surface-Area Materials** Carbon nanotubes have remarkable mechanical and electrical properties. But, a possible future application for them is in storing  $\text{H}_2$  gas for hydrogen-powered vehicles. Currently,  $\text{H}_2$  is stored in metal cylinders at high pressures ( $>70$  atm). Porous solids, such as carbon nanotubes, can store the same amount of gas at much lower pressures because they have surface areas of  $4500 \text{ m}^2/\text{g}$ —about four football fields per gram of material! Thus, a medium-sized container of nanotubes could store a large amount of  $\text{H}_2$  fuel under conditions safe enough for a family car.

Other high-surface-area materials being developed are porous membranes for water purification or batteries and multilayer films that incorporate photosynthetic molecules for high-efficiency solar cells. A very exciting development is a molecule-specific biosensor, which can detect as little as  $10^{-14}$  mol of DNA using color changes in gold nanoparticles. Such biosensors could circulate freely in the bloodstream to measure levels of specific disease-related molecules, deliver drugs to individual cells, and even alter individual genes.

**Nanomachines** In nature, a virus is a marvel of nanoscale engineering, designed for delivering genetic material to infect a host cell. For example, the T4 virus latches onto a bacterial cell with its tail fibers, bores through the bacterial membrane with its end plate, and then injects the payload of DNA, packaged in its head, into the bacterium. These complex functions are performed by a biological “machine” measuring 60 by 200 nm. Researchers are exploring ways for viruses to deliver medicinal agents to specific cells. In other feats of nanoscale engineering, researchers have created nanovalves, nanopropellers, and even a nanocar, complete with a chassis, axles, and buckyball wheels, that is only 4 nm wide and is “driven” on a gold surface under the direction of an atomic force microscope (Figure 12.51).

## › Summary of Section 12.7

- › Doping increases the conductivity of semiconductors and is essential to modern electronic materials. Doping silicon with Group 5A(15) atoms introduces negative sites (creating an n-type semiconductor) by adding valence electrons to the conduction band, whereas doping with Group 3A(13) atoms adds positive holes (for a p-type semiconductor) by emptying some orbitals in the valence band. Placing these two types of semiconductors in contact with one another forms a p-n junction. Sandwiching a p-type portion between two n-type portions forms a transistor.
- › Liquid crystal phases flow like liquids but have molecules ordered like crystalline solids. Typically, the molecules have rodlike shapes, and their intermolecular forces keep them aligned. Thermotropic phases are prepared by heating the solid; lyotropic phases form when the solvent concentration is varied. The nematic, cholesteric, and smectic phases of liquid crystals differ in their molecular order. Liquid crystal applications depend on controlling the orientation of the molecules.
- › Ceramics are very resistant to heat and chemicals. Most are network covalent solids formed at high temperature from simple reactants. They add lightweight strength to other materials.
- › Polymers are extremely large molecules that adopt the shape of a random coil, as a result of intermolecular forces. A polymer sample has an average molar mass because it consists of chains with a range of lengths. The high viscosity of a polymer arises from attractions between chains or, in the case of a dissolved polymer, between chains and solvent. By varying the degrees of branching, crosslinking, and ordering (crystallinity), chemists tailor polymers with specific properties.
- › Nanoscale materials can be made through construction processes involving self-assembly and controlled orientation of molecules.

## CHAPTER REVIEW GUIDE

### Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

#### Understand These Concepts

- How the interplay between kinetic and potential energy underlies the properties of the three states of matter and their phase changes (§12.1)
- The processes involved, both within a phase and during a phase change, when heat is added or removed from a pure substance (§12.2)
- The meaning of vapor pressure and how phase changes are dynamic equilibrium processes (§12.2)
- How temperature and intermolecular forces influence vapor pressure (§12.2)
- The relation between vapor pressure and boiling point (§12.2)
- How a phase diagram shows the phases of a substance at differing conditions of pressure and temperature (§12.2)
- The distinction between bonding and intermolecular forces on the basis of Coulomb's law and the meaning of the van der Waals radius of an atom (§12.3)
- The types and relative strengths of intermolecular forces acting in a substance (dipole-dipole, H bonding, dispersion), the impact of H bonding on physical properties, and the meaning of polarizability (§12.3)
- The meanings of surface tension, capillarity, and viscosity and how intermolecular forces influence their magnitudes (§12.4)
- How the important macroscopic properties of water arise from atomic and molecular properties (§12.5)
- The structure of a crystal lattice and the characteristics of the three types of cubic unit cells (§12.6)
- How packing of spheres gives rise to the hexagonal and cubic unit cells (§12.6)
- Types of crystalline solids and how their intermolecular forces give rise to their properties (§12.6)
- How band theory accounts for the properties of metals and the relative conductivities of metals, nonmetals, and metalloids (§12.6)
- The structures, properties, and functions of modern materials (doped semiconductors, liquid crystals, ceramics, polymers, and nanostructures) (§12.7)

#### Master These Skills

- Calculating the overall enthalpy change when heat is gained or lost by a pure substance (§12.2 and SP 12.1)
- Using the Clausius-Clapeyron equation to examine the relationship between vapor pressure and temperature (SP 12.2)
- Using a phase diagram to predict the phase changes of a substance (§12.2 and SP 12.3)
- Determining whether a substance can form H bonds and drawing the H-bonded structures (SP 12.4)
- Predicting the types and relative strength of the bonding and intermolecular forces acting within a substance from its structure (SP 12.5)
- Finding the number of particles per unit cell and the coordination number of a crystalline solid (§12.6 and SP 12.6)
- Calculating atomic radius from the density and/or crystal structure of an element (SPs 12.7, 12.8)

### Key Terms

Page numbers appear in parentheses.

amorphous solid (495)	cubic closest packing (500)	hydrogen bond (H bond) (486)	plastic (519)
atomic solid (504)	degree of polymerization ( $n$ ) (516)	insulator (508)	polarizability (488)
band theory (506)	deposition (473)	intermolecular forces (471)	polymer (516)
body-centered cubic unit cell (496)	dipole-dipole force (485)	ion-dipole force (485)	radius of gyration ( $R_g$ ) (517)
boiling point (481)	dispersion (London) force (488)	ionic solid (504)	random coil (517)
branch (519)	doping (510)	lattice (496)	scanning tunneling microscopy (502)
capillarity (491)	elastomer (520)	liquid crystal (511)	semiconductor (508)
ceramic (514)	face-centered cubic unit cell (496)	London force (488)	simple cubic unit cell (496)
Clausius-Clapeyron equation (480)	freezing (473)	macromolecule (516)	sublimation (473)
condensation (473)	fusion (473)	melting point (481)	superconductivity (508)
conduction band (507)	heat of fusion ( $\Delta H_{\text{fus}}^\circ$ ) (473)	melting (fusion) (473)	surface tension (491)
conductor (508)	heat of sublimation ( $\Delta H_{\text{subl}}^\circ$ ) (474)	metallic solid (505)	triple point (482)
coordination number (496)	heat of vaporization ( $\Delta H_{\text{vap}}^\circ$ ) (473)	molecular solid (504)	unit cell (496)
copolymer (520)	heating-cooling curve (475)	monomer (516)	valence band (507)
critical point (482)	hexagonal closest packing (500)	nanotechnology (521)	van der Waals radius (484)
crosslink (520)		network covalent solid (505)	vapor pressure (479)
crystal defect (509)		packing efficiency (498)	vaporization (473)
crystalline solid (495)		phase (471)	viscosity (492)
		phase change (472)	x-ray diffraction analysis (502)
		phase diagram (482)	

### Key Equations and Relationships

Page number appears in parentheses.

**12.1** Using the vapor pressure at one temperature to find the vapor pressure at another temperature (two-point form of the Clausius-Clapeyron equation) (480):

$$\ln \frac{P_2}{P_1} = \frac{-\Delta H_{\text{vap}}}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right)$$

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

**12.1A** The scenes represent solid water at  $-7.00^\circ\text{C}$  melting to liquid water at  $16.0^\circ\text{C}$ , so heat is absorbed by the system ( $q$  is positive). There are three stages:

Stage 1, increasing the temperature of ice to the melting point:

$$q = n \times C_{m(\text{water}, s)} \times \Delta T = (2.25 \text{ mol}) (37.6 \text{ J/mol}\cdot^\circ\text{C}) [0^\circ\text{C} - (-7.00^\circ\text{C})] = 592 \text{ J} = 0.592 \text{ kJ}$$

Stage 2, melting the ice:  $\text{H}_2\text{O}(s) [0.00^\circ\text{C}] \longrightarrow \text{H}_2\text{O}(l) [0.00^\circ\text{C}]:$

$$q = n(\Delta H_{\text{fus}}^\circ) = (2.25 \text{ mol})(6.02 \text{ kJ/mol}) = 13.5 \text{ kJ}$$

Stage 3, increasing the temperature of the water:

$$q = n \times C_{m(\text{water}, l)} \times \Delta T = (2.25 \text{ mol})(75.4 \text{ J/mol}\cdot^\circ\text{C})(16.0^\circ\text{C} - 0^\circ\text{C}) = 2714 \text{ J} = 2.71 \text{ kJ}$$

$$\text{Total heat (kJ)} = 0.592 \text{ kJ} + 13.5 \text{ kJ} + 2.71 \text{ kJ} = 16.8 \text{ kJ}$$

**12.1B** The scenes represent gaseous bromine at  $73.5^\circ\text{C}$  condensing to liquid bromine at  $23.8^\circ\text{C}$ , so heat is released by the system ( $q$  is negative). First convert mass to moles:

$$\text{Amount (mol) Br}_2 = 47.94 \text{ g Br}_2 \times \frac{1 \text{ mol Br}_2}{159.8 \text{ g Br}_2} = 0.3000 \text{ mol Br}_2$$

There are three stages:

Stage 1, cooling the gas:  $\text{Br}_2(g) [73.5^\circ\text{C}] \longrightarrow \text{Br}_2(g) [59.5^\circ\text{C}]:$

$$q = n \times C_{m(\text{Br}_2, g)} \times \Delta T = (0.3000 \text{ mol}) (36.0 \text{ J/mol}\cdot^\circ\text{C}) (59.5^\circ\text{C} - 73.5^\circ\text{C}) = -151 \text{ J} = -0.151 \text{ kJ}$$

Stage 2, condensing the gas to liquid at the boiling point:

$$q = n(-\Delta H_{\text{vap}}^\circ) = (0.3000 \text{ mol})(-29.6 \text{ kJ/mol}) = -8.88 \text{ kJ}$$

Stage 3, cooling the liquid:  $\text{Br}_2(l) [59.5^\circ\text{C}] \longrightarrow \text{Br}_2(l) [23.8^\circ\text{C}]:$

$$q = n \times C_{m(\text{Br}_2, l)} \times \Delta T = (0.3000 \text{ mol})(75.7 \text{ J/mol}\cdot^\circ\text{C})(23.8^\circ\text{C} - 59.5^\circ\text{C}) = -811 \text{ J} = -0.811 \text{ kJ}$$

$$\text{Total heat (kJ)} = -0.151 \text{ kJ} + (-8.88 \text{ kJ}) + (-0.811 \text{ kJ}) = -9.84 \text{ kJ}$$

$$\begin{aligned} \mathbf{12.2A} \quad \ln \frac{P_2}{P_1} &= \frac{-\Delta H_{\text{vap}}}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right) \\ \ln \frac{P_2}{P_1} &= \left( \frac{-40.7 \times 10^3 \text{ J/mol}}{8.314 \text{ J/mol}\cdot\text{K}} \right) \\ &\quad \times \left( \frac{1}{273.15 + 85.5 \text{ K}} - \frac{1}{273.15 + 34.1 \text{ K}} \right) \end{aligned}$$

$$\ln \frac{P_2}{P_1} = (-4.90 \times 10^3 \text{ K})(-4.66 \times 10^{-4} \text{ K}^{-1}) = 2.28$$

$$\frac{P_2}{P_1} = 9.8$$

$$\frac{P_2}{40.1 \text{ torr}} = 9.8; \quad P_2 = 40.1 \text{ torr} \times 9.8 = 390 \text{ torr}$$

$$\begin{aligned} \mathbf{12.2B} \quad \ln \frac{P_2}{P_1} &= \frac{-\Delta H_{\text{vap}}}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right) \\ \ln \frac{24.50 \text{ kPa}}{10.00 \text{ kPa}} &= \frac{-\Delta H_{\text{vap}}}{8.314 \text{ J/K}\cdot\text{mol}} \\ &\quad \times \left( \frac{1}{273.15 + 20.2 \text{ K}} - \frac{1}{273.15 + 0.95 \text{ K}} \right) \end{aligned}$$

$$0.8961 = \frac{-\Delta H_{\text{vap}}}{8.314 \text{ J/K}\cdot\text{mol}} \times (-0.0002394 \text{ K}^{-1})$$

$$\Delta H_{\text{vap}} = 3.11 \times 10^4 \text{ J/mol} = 31.1 \text{ kJ/mol}$$

**12.3A** At the starting conditions ( $3 \times 10^2$  bar and 2000 K; point  $c$ ), the carbon sample is in the form of graphite. As the sample is heated at constant pressure, it melts at around 4500 K, and then vaporizes at around 5000 K.

**12.3B** At the starting conditions (4600 K and  $10^4$  bar; point  $d$ ), the carbon sample is in the form of graphite. As the sample is compressed at constant temperature, it melts at around  $4 \times 10^4$  bar and then solidifies to diamond at around  $2 \times 10^5$  bar.

**12.4A**

(c) No H bonding (H is not bonded to O in this molecule.)

**12.4B** (a) No H bonding (H is not bonded to O in this molecule.)

**12.5A** (a) Both molecules are polar (tetrahedral molecular geometry). Dipole-dipole and dispersion forces are present for both;  $\text{CH}_3\text{Br}$  has the higher boiling point because it has the larger molar mass.

(b) H bonding in  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ , dipole-dipole and dispersion in both;  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$  has the higher boiling point due to the H bonding.

(c) Both are nonpolar molecules. Dispersion forces;  $\text{C}_3\text{H}_8$  has the higher boiling point because it has the larger molar mass.

**12.5B** (a) Dispersion and dipole-dipole forces in both, H bonding in  $\text{CH}_3\text{CH}_2\text{OH}$ ;  $\text{CH}_3\text{CHO}$  has the lower boiling point since it does not have H bonding.

(b)  $\text{SO}_2$  molecules, with a bent molecular geometry, are polar and have dispersion and dipole-dipole forces;  $\text{CO}_2$ , which is a linear molecule, has only dispersion forces. With the weaker forces,  $\text{CO}_2$  has the lower boiling point.

(c) Dispersion and dipole-dipole forces in both molecules; H bonding in  $\text{H}_2\text{N}-\text{C}(\text{O})-\text{CH}_2\text{CH}_3$ ;  $(\text{CH}_3)_2\text{N}-\text{CH}(\text{O})-\text{CH}_3$  has the lower

boiling point since it does not have H bonding.

**12.6A** (a)  $\text{PbS}$ :  $\text{Pb}^{2+}$  ions/unit cell =  $\text{S}^{2-}$  ions/unit cell =  $(8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4 \text{ Pb}^{2+}$  and  $4 \text{ S}^{2-}$  ions; coordination number of each ion is 6.

(b)  $\text{W}$ : Atoms/unit cell =  $(8 \times \frac{1}{8}) + 1 = 2$ ; coordination number is 8.

(c)  $\text{Al}$ : Atoms/unit cell =  $(8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4$ ; coordination number is 12.

**12.6B** (a) K: Atoms/unit cell =  $(8 \times \frac{1}{8}) + 1 = 2$ ; coordination number is 8.

(b) Pt: Atoms/unit cell =  $(8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4$ ; coordination number is 12.

(c) CsCl:  $\text{Cs}^+$  ions/unit cell =  $(8 \times \frac{1}{8}) = 1$ ;  $\text{Cl}^-$  ions/unit cell = 1; coordination number of each ion is 8.

**12.7A** The packing efficiency in the face-centered cubic cell is 74%.

$$\begin{aligned} V \text{ of Co atom} &= \frac{4}{3}\pi r^3 = \frac{4}{3}(3.14)(125 \text{ pm})^3 \\ &= \frac{8.18 \times 10^6 \text{ pm}^3}{\text{atom}} \end{aligned}$$

$$\begin{aligned} V \text{ of 1 mol of Co atoms (cm}^3\text{)} \\ &= \frac{8.18 \times 10^6 \text{ pm}^3}{\text{atom}} \times \frac{6.022 \times 10^{23} \text{ atoms}}{\text{mol atoms}} \times \frac{1 \text{ cm}^3}{10^{30} \text{ pm}^3} \\ &= 4.93 \text{ cm}^3/\text{mol atoms} \end{aligned}$$

$$\begin{aligned} V \text{ of 1 mol of Co metal (cm}^3\text{)} &= \frac{4.93 \text{ cm}^3/\text{mol atoms}}{0.74} \\ &= 6.66 \text{ cm}^3/\text{mol Co metal} \end{aligned}$$

$$d \text{ of Co metal} = \frac{58.93 \text{ g}}{\text{mol}} \times \frac{1 \text{ mol}}{6.66 \text{ cm}^3} = 8.85 \text{ g/cm}^3$$

**12.7B** The packing efficiency in the body-centered cubic cell is 68%.

$$\begin{aligned} \text{Avogadro's no.} &= \frac{1 \text{ cm}^3}{7.874 \text{ g Fe}} \times \frac{55.85 \text{ g Fe}}{1 \text{ mol Fe}} \times 0.68 \\ &\times \frac{1 \text{ Fe atom}}{8.38 \times 10^{-24} \text{ cm}^3} \\ &= 5.8 \times 10^{23} \text{ Fe atoms/mol Fe} \end{aligned}$$

**12.8A** From Figure 12.29,

$$\begin{aligned} A \text{ (nm)} &= \frac{4r}{\sqrt{3}} = \frac{4(126 \text{ pm})}{\sqrt{3}} = 291 \text{ pm} \times \frac{1 \text{ nm}}{1000 \text{ pm}} \\ &= 0.291 \text{ nm} \end{aligned}$$

**12.8B**  $A = \sqrt{8}r$

$$r = A/\sqrt{8} = 0.405 \text{ nm}/\sqrt{8} = 0.143 \text{ nm} = 143 \text{ pm}$$

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

### An Overview of Physical States and Phase Changes

#### Concept Review Questions

**12.1** How does the energy of attraction between particles compare with their energy of motion in a gas and in a solid? As part of your answer, identify two macroscopic properties that differ between a gas and a solid.

**12.2** (a) Why are gases more easily compressed than liquids? (b) Why do liquids have a greater ability to flow than solids?

**12.3** What type of forces, intramolecular or intermolecular: (a) Prevent ice cubes from adopting the shape of their container? (b) Are overcome when ice melts? (c) Are overcome when liquid water is vaporized? (d) Are overcome when gaseous water is converted to hydrogen gas and oxygen gas?

**12.4** (a) Why is the heat of fusion ( $\Delta H_{\text{fus}}$ ) of a substance smaller than its heat of vaporization ( $\Delta H_{\text{vap}}$ )? (b) Why is the heat of sublimation ( $\Delta H_{\text{subl}}$ ) of a substance greater than its  $\Delta H_{\text{vap}}$ ? (c) At a given temperature and pressure, how does the magnitude of the heat of vaporization of a substance compare with that of its heat of condensation?

#### Skill-Building Exercises (grouped in similar pairs)

- 12.5** Which forces are intramolecular and which intermolecular? (a) Those preventing oil from evaporating at room temperature (b) Those preventing butter from melting in a refrigerator (c) Those allowing silver to tarnish (d) Those preventing  $\text{O}_2$  in air from forming O atoms
- 12.6** Which forces are intramolecular and which intermolecular? (a) Those allowing fog to form on a cool, humid evening (b) Those allowing water to form when  $\text{H}_2$  is sparked (c) Those allowing liquid benzene to crystallize when cooled (d) Those responsible for the low boiling point of hexane

**12.7** Name the phase change in each of these events: (a) Dew appears on a lawn in the morning. (b) Icicles change into liquid water. (c) Wet clothes dry on a summer day.

**12.8** Name the phase change in each of these events: (a) A diamond film forms on a surface from gaseous carbon atoms in a vacuum. (b) Mothballs in a bureau drawer disappear over time. (c) Molten iron from a blast furnace is cast into ingots (“pigs”).

#### Problems in Context

**12.9** Liquid propane, a widely used fuel, is produced by compressing gaseous propane. During the process, approximately 15 kJ of energy is released for each mole of gas liquefied. Where does this energy come from?

**12.10** Many heat-sensitive and oxygen-sensitive solids, such as camphor, are purified by warming under vacuum. The solid vaporizes directly, and the vapor crystallizes on a cool surface. What phase changes are involved in this method?

**Quantitative Aspects of Phase Changes**

(Sample Problems 12.1–12.3)

**Concept Review Questions**

**12.11** Describe the changes (if any) in potential energy and in kinetic energy among the molecules when gaseous  $\text{PCl}_3$  condenses to a liquid at a fixed temperature.

**12.12** When benzene is at its melting point, two processes occur simultaneously and balance each other. Describe these processes on the macroscopic and molecular levels.

**12.13** Liquid hexane (bp =  $69^\circ\text{C}$ ) is placed in a closed container at room temperature. At first, the pressure of the vapor phase increases, but after a short time, it stops changing. Why?

**12.14** Explain the effect of strong intermolecular forces on each of these parameters: (a) critical temperature; (b) boiling point; (c) vapor pressure; (d) heat of vaporization.

**12.15** Match each numbered point in the phase diagram for compound Q with the correct molecular scene below:

**12.16** A liquid is in equilibrium with its vapor in a closed vessel at a fixed temperature. The vessel is connected by a stopcock to an evacuated vessel. When the stopcock is opened, will the final pressure of the vapor be different from the initial value if (a) some liquid remains; (b) all the liquid is first removed? Explain.

**12.17** The phase diagram for substance A has a solid-liquid line with a positive slope, and that for substance B has a solid-liquid line with a negative slope. What macroscopic property can distinguish A from B?

**12.18** Why does water vapor at  $100^\circ\text{C}$  cause a more severe burn than liquid water at  $100^\circ\text{C}$ ?

**Skill-Building Exercises (grouped in similar pairs)**

**12.19** From the data below, calculate the total heat (in J) needed to convert 22.00 g of ice at  $-6.00^\circ\text{C}$  to liquid water at  $0.500^\circ\text{C}$ :

mp at 1 atm:  $0.0^\circ\text{C}$        $\Delta H_{\text{fus}}^\circ$ : 6.02 kJ/mol  
 $c_{\text{liquid}}$ : 4.21 J/g $\cdot^\circ\text{C}$        $c_{\text{solid}}$ : 2.09 J/g $\cdot^\circ\text{C}$

**12.20** From the data below, calculate the total heat (in J) needed to convert 0.333 mol of gaseous ethanol at  $300^\circ\text{C}$  and 1 atm to liquid ethanol at  $25.0^\circ\text{C}$  and 1 atm:

bp at 1 atm:  $78.5^\circ\text{C}$        $\Delta H_{\text{vap}}^\circ$ : 40.5 kJ/mol  
 $c_{\text{gas}}$ : 1.43 J/g $\cdot^\circ\text{C}$        $c_{\text{liquid}}$ : 2.45 J/g $\cdot^\circ\text{C}$

**12.21** A liquid has a  $\Delta H_{\text{vap}}^\circ$  of 35.5 kJ/mol and a boiling point of  $122^\circ\text{C}$  at 1.00 atm. What is its vapor pressure at  $113^\circ\text{C}$ ?

**12.22** Diethyl ether has a  $\Delta H_{\text{vap}}^\circ$  of 29.1 kJ/mol and a vapor pressure of 0.703 atm at  $25.0^\circ\text{C}$ . What is its vapor pressure at  $95.0^\circ\text{C}$ ?

**12.23** What is the  $\Delta H_{\text{vap}}^\circ$  of a liquid that has a vapor pressure of 621 torr at  $85.2^\circ\text{C}$  and a boiling point of  $95.6^\circ\text{C}$  at 1 atm?

**12.24** Methane ( $\text{CH}_4$ ) has a boiling point of  $-164^\circ\text{C}$  at 1 atm and a vapor pressure of 42.8 atm at  $-100^\circ\text{C}$ . What is the heat of vaporization of  $\text{CH}_4$ ?

**12.25** Use these data to draw a qualitative phase diagram for ethylene ( $\text{C}_2\text{H}_4$ ). Is  $\text{C}_2\text{H}_4(\text{s})$  more or less dense than  $\text{C}_2\text{H}_4(\text{l})$ ?

bp at 1 atm:  $-103.7^\circ\text{C}$

mp at 1 atm:  $-169.16^\circ\text{C}$

Critical point:  $9.9^\circ\text{C}$  and 50.5 atm

Triple point:  $-169.17^\circ\text{C}$  and  $1.20 \times 10^{-3}$  atm

**12.26** Use these data to draw a qualitative phase diagram for  $\text{H}_2$ . Does  $\text{H}_2$  sublime at 0.05 atm? Explain.

mp at 1 atm: 13.96 K

bp at 1 atm: 20.39 K

Triple point: 13.95 K and 0.07 atm

Critical point: 33.2 K and 13.0 atm

Vapor pressure of solid at 10 K: 0.001 atm

**12.27** The phase diagram for sulfur is shown below.

(a) Give a set of conditions under which it is possible to sublime the rhombic form of solid sulfur.

(b) Describe the phase changes that a sample of sulfur undergoes at 1 atm when it is heated from  $90^\circ\text{C}$  to  $450^\circ\text{C}$ .

**12.28** The phase diagram for xenon is shown below.

(a) What phase is xenon in at room temperature and pressure?

(b) Describe the phase changes that a sample of xenon undergoes at  $-115^\circ\text{C}$  as it is compressed from 0.5 atm to 25 atm. (The critical pressure of xenon is 58 atm.)

### Problems in Context

**12.29** Sulfur dioxide is produced in enormous amounts for sulfuric acid production. It melts at  $-73^{\circ}\text{C}$  and boils at  $-10.^{\circ}\text{C}$ . Its  $\Delta H_{\text{fus}}^{\circ}$  is  $8.619\text{ kJ/mol}$ , and its  $\Delta H_{\text{vap}}^{\circ}$  is  $25.73\text{ kJ/mol}$ . The specific heat capacities of the liquid and gas are  $0.995\text{ J/g}\cdot\text{K}$  and  $0.622\text{ J/g}\cdot\text{K}$ , respectively. How much heat is required to convert  $2.500\text{ kg}$  of solid  $\text{SO}_2$  at the melting point to a gas at  $60.^{\circ}\text{C}$ ?

**12.30** Butane is a common fuel used in cigarette lighters and camping stoves. Normally supplied in metal containers under pressure, the fuel exists as a mixture of liquid and gas, so high temperatures may cause the container to explode. At  $25.0^{\circ}\text{C}$ , the vapor pressure of butane is  $2.3\text{ atm}$ . What is the pressure in the container at  $135^{\circ}\text{C}$  ( $\Delta H_{\text{vap}}^{\circ} = 24.3\text{ kJ/mol}$ )?

**12.31** Use Figure 12.10 to answer the following:

- (a) Carbon dioxide is sold in steel cylinders under a pressure of approximately  $20\text{ atm}$ . Is there liquid  $\text{CO}_2$  in the cylinder at room temperature ( $\sim 20^{\circ}\text{C}$ )? At  $40^{\circ}\text{C}$ ? At  $-40^{\circ}\text{C}$ ? At  $-120^{\circ}\text{C}$ ?  
 (b) Carbon dioxide is also sold as solid chunks, called *dry ice*, in insulated containers. If the chunks are warmed by leaving them in an open container at room temperature, will they melt?  
 (c) If a container is nearly filled with dry ice and then sealed and warmed to room temperature, will the dry ice melt?  
 (d) If dry ice is compressed at a temperature below its triple point, will it melt?

### Types of Intermolecular Forces

(Sample Problems 12.4 and 12.5)

### Concept Review Questions

**12.32** Why are covalent bonds typically much stronger than intermolecular forces?

- 12.33** (a) Name the type of force depicted in each scene below.  
 (b) Rank the forces in order of increasing strength.

**12.34** Oxygen and selenium are members of Group 6A(16). Water forms H bonds, but  $\text{H}_2\text{Se}$  does not. Explain.

**12.35** In solid  $\text{I}_2$ , is the distance between the two I nuclei of one  $\text{I}_2$  molecule longer or shorter than the distance between two I nuclei of adjacent  $\text{I}_2$  molecules? Explain.

**12.36** Polar molecules exhibit dipole-dipole forces. Do they also exhibit dispersion forces? Explain.

**12.37** Distinguish between *polarizability* and *polarity*. How does each influence intermolecular forces?

**12.38** How can one nonpolar molecule induce a dipole in a nearby nonpolar molecule?

### Skill-Building Exercises (grouped in similar pairs)

**12.39** What is the strongest interparticle force in each substance?  
 (a)  $\text{CH}_3\text{OH}$  (b)  $\text{CCl}_4$  (c)  $\text{Cl}_2$

**12.40** What is the strongest interparticle force in each substance?  
 (a)  $\text{H}_3\text{PO}_4$  (b)  $\text{SO}_2$  (c)  $\text{MgCl}_2$

**12.41** What is the strongest interparticle force in each substance?  
 (a)  $\text{CH}_3\text{Cl}$  (b)  $\text{CH}_3\text{CH}_3$  (c)  $\text{NH}_3$

**12.42** What is the strongest interparticle force in each substance?  
 (a) Kr (b) BrF (c)  $\text{H}_2\text{SO}_4$

**12.43** Which member of each pair of compounds forms intermolecular H bonds? Draw the H-bonded structures in each case:

- (a)  $\text{CH}_3\text{CH}(\text{OH})\text{CH}_3$  or  $\text{CH}_3\text{SCH}_3$  (b) HF or HBr

**12.44** Which member of each pair of compounds forms intermolecular H bonds? Draw the H-bonded structures in each case:

- (a)  $(\text{CH}_3)_2\text{NH}$  or  $(\text{CH}_3)_3\text{N}$  (b)  $\text{HOCH}_2\text{CH}_2\text{OH}$  or  $\text{FCH}_2\text{CH}_2\text{F}$

**12.45** Which forces oppose vaporization of each substance?

- (a) Hexane (b) Water (c)  $\text{SiCl}_4$

**12.46** Which forces oppose vaporization of each substance?

- (a)  $\text{Br}_2$  (b)  $\text{SbH}_3$  (c)  $\text{CH}_3\text{NH}_2$

**12.47** Which species in each pair has the greater polarizability? Explain.

- (a)  $\text{Br}^-$  or  $\text{I}^-$  (b)  $\text{CH}_2=\text{CH}_2$  or  $\text{CH}_3-\text{CH}_3$  (c)  $\text{H}_2\text{O}$  or  $\text{H}_2\text{Se}$

**12.48** Which species in each pair has the greater polarizability? Explain.

- (a)  $\text{Ca}^{2+}$  or Ca (b)  $\text{CH}_3\text{CH}_3$  or  $\text{CH}_3\text{CH}_2\text{CH}_3$  (c)  $\text{CCl}_4$  or  $\text{CF}_4$

**12.49** Which liquid in each pair has the *higher* vapor pressure at a given temperature? Explain.

- (a)  $\text{C}_2\text{H}_6$  or  $\text{C}_4\text{H}_{10}$  (b)  $\text{CH}_3\text{CH}_2\text{OH}$  or  $\text{CH}_3\text{CH}_2\text{F}$   
 (c)  $\text{NH}_3$  or  $\text{PH}_3$

**12.50** Which liquid in each pair has the *lower* vapor pressure at a given temperature? Explain.

- (a)  $\text{HOCH}_2\text{CH}_2\text{OH}$  or  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$   
 (b)  $\text{CH}_3\text{COOH}$  or  $(\text{CH}_3)_2\text{C}=\text{O}$  (c) HF or HCl

**12.51** Which substance has the *lower* boiling point? Explain.

- (a) LiCl or HCl (b)  $\text{NH}_3$  or  $\text{PH}_3$  (c) Xe or  $\text{I}_2$

**12.52** Which substance has the *higher* boiling point? Explain.

- (a)  $\text{CH}_3\text{CH}_2\text{OH}$  or  $\text{CH}_3\text{CH}_2\text{CH}_3$  (b) NO or  $\text{N}_2$   
 (c)  $\text{H}_2\text{S}$  or  $\text{H}_2\text{Te}$

**12.53** Which substance has the *lower* boiling point? Explain.

- (a)  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_3$  or  $\begin{array}{c} \text{CH}_2-\text{CH}_2 \\ | \quad | \\ \text{CH}_2-\text{CH}_2 \end{array}$  (b) NaBr or  $\text{PBr}_3$

(c)  $\text{H}_2\text{O}$  or HBr

**12.54** Which substance has the *higher* boiling point? Explain.

- (a)  $\text{CH}_3\text{OH}$  or  $\text{CH}_3\text{CH}_3$  (b) FNO or ClNO

### Problems in Context

**12.55** For pairs of molecules in the gas phase, average H-bond dissociation energies are  $17\text{ kJ/mol}$  for  $\text{NH}_3$ ,  $22\text{ kJ/mol}$  for  $\text{H}_2\text{O}$ , and  $29\text{ kJ/mol}$  for HF. Explain this increase in H-bond strength.

**12.56** Dispersion forces are the only intermolecular forces present in motor oil, yet it has a high boiling point. Explain.

**12.57** Why does the antifreeze ingredient ethylene glycol ( $\text{HOCH}_2\text{CH}_2\text{OH}$ ;  $\mathcal{M} = 62.07\text{ g/mol}$ ) have a boiling point of  $197.6^{\circ}\text{C}$ , whereas propanol ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ ;  $\mathcal{M} = 60.09\text{ g/mol}$ ), a compound with a similar molar mass, has a boiling point of only  $97.4^{\circ}\text{C}$ ?

### Properties of the Liquid State

#### Concept Review Questions

**12.58** Before the phenomenon of surface tension was understood, physicists described the surface of water as being covered with a "skin." What causes this skinlike phenomenon?

**12.59** Small, equal-sized drops of oil, water, and mercury lie on a waxed floor. How does each liquid behave? Explain.

**12.60** Why does an aqueous solution of ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) have a lower surface tension than water?

**12.61** Why are units of energy per area ( $\text{J}/\text{m}^2$ ) used for surface tension values?

**12.62** Does the *strength* of the intermolecular forces in a liquid change as the liquid is heated? Explain. Why does a liquid's viscosity decrease with rising temperature?

### Skill-Building Exercises (grouped in similar pairs)

**12.63** Rank the following in order of *increasing* surface tension at a given temperature, and explain your ranking:

- (a)  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$       (b)  $\text{HOCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH}$   
(c)  $\text{HOCH}_2\text{CH}_2\text{OH}$

**12.64** Rank the following in order of *decreasing* surface tension at a given temperature, and explain your ranking:

- (a)  $\text{CH}_3\text{OH}$       (b)  $\text{CH}_3\text{CH}_3$       (c)  $\text{H}_2\text{C}=\text{O}$

**12.65** Rank the compounds in Problem 12.63 in order of *decreasing* viscosity at a given temperature; explain your ranking.

**12.66** Rank the compounds in Problem 12.64 in order of *increasing* viscosity at a given temperature; explain your ranking.

### Problems in Context

**12.67** Soil vapor extraction (SVE) is used to remove volatile organic pollutants, such as chlorinated solvents, from soil at hazardous waste sites. Vent wells are drilled, and a vacuum pump is applied to the subsurface. (a) How does this method remove pollutants? (b) Why does heating combined with SVE speed the process?

**12.68** Use Figure 12.2, to answer the following: (a) Does it take more heat to melt 12.0 g of  $\text{CH}_4$  or 12.0 g of  $\text{Hg}$ ? (b) Does it take more heat to vaporize 12.0 g of  $\text{CH}_4$  or 12.0 g of  $\text{Hg}$ ? (c) What is the principal intermolecular force in each sample?

**12.69** Pentanol ( $\text{C}_5\text{H}_{11}\text{OH}$ ;  $\mathcal{M} = 88.15 \text{ g/mol}$ ) has nearly the same molar mass as hexane ( $\text{C}_6\text{H}_{14}$ ;  $\mathcal{M} = 86.17 \text{ g/mol}$ ) but is more than 12 times as viscous at  $20^\circ\text{C}$ . Explain.

### The Uniqueness of Water

#### Concept Review Questions

**12.70** For what types of substances is water a good solvent? For what types is it a poor solvent? Explain.

**12.71** A water molecule can engage in as many as four H bonds. Explain.

**12.72** Warm-blooded animals have a narrow range of body temperature because their bodies have a high water content. Explain.

**12.73** What property of water keeps plant debris on the surface of lakes and ponds? What is the ecological significance of this?

**12.74** A drooping plant can be made to stand upright by watering the ground around it. Explain.

**12.75** Describe the molecular basis of the property of water responsible for the presence of ice on the surface of a frozen lake.

**12.76** Describe in molecular terms what occurs when ice melts.

### The Solid State: Structure, Properties, and Bonding

(Sample Problems 12.6–12.8)

#### Concept Review Questions

**12.77** What is the difference between an amorphous solid and a crystalline solid on the macroscopic and molecular levels? Give an example of each.

**12.78** How are a solid's unit cell and crystal structure related?

**12.79** For structures consisting of identical atoms, how many atoms are contained in a simple cubic, a body-centered cubic, and a face-centered cubic unit cell? Explain how you obtained the values.

**12.80** An element has a crystal structure in which the width of the cubic unit cell equals the diameter of an atom. What type of unit cell does it have?

**12.81** What specific difference in the positioning of spheres gives a crystal structure based on the face-centered cubic unit cell less empty space than one based on the body-centered cubic unit cell?

**12.82** Both solid Kr and solid Cu consist of individual atoms. Why do their physical properties differ so much?

**12.83** What is the energy gap in band theory? Compare its size in superconductors, conductors, semiconductors, and insulators.

**12.84** Predict the effect (if any) of an increase in temperature on the electrical conductivity of (a) a conductor; (b) a semiconductor; (c) an insulator.

**12.85** Besides the type of unit cell, what information is needed to find the density of a solid consisting of identical atoms?

### Skill-Building Exercises (grouped in similar pairs)

**12.86** What type of unit cell does each metal use in its crystal lattice? (The number of atoms per unit cell is given in parentheses.)

- (a) Ni (4)      (b) Cr (2)      (c) Ca (4)

**12.87** What is the number of atoms per unit cell for each metal?

- (a) Polonium, Po      (b) Manganese, Mn      (c) Silver, Ag

**12.88** Calcium crystallizes in a cubic closest packed structure. If the atomic radius of calcium is 197 pm, find the density of the solid.

**12.89** Chromium adopts the body-centered cubic unit cell in its crystal structure. If the density of chromium is  $7.14 \text{ g/cm}^3$ , find its atomic radius.

**12.90** When cadmium oxide reacts to form cadmium selenide, a change in unit cell occurs, as depicted below:

(a) What is the change in unit cell?

(b) Does the coordination number of cadmium change? Explain.

**12.91** As molten iron cools to 1674 K, it adopts one type of cubic unit cell; then, as the temperature drops below 1181 K, it changes to another, as depicted below:

(a) What is the change in unit cell?

(b) Which crystal structure has the greater packing efficiency?

**12.92** Potassium adopts the body-centered cubic unit cell in its crystal structure. If the atomic radius of potassium is 227 pm, find the edge length of the unit cell.

**12.93** Lead adopts the face-centered cubic unit cell in its crystal structure. If the edge length of the unit cell is 495 pm, find the atomic radius of lead.

**12.94** Of the five major types of crystalline solid, which does each of the following form, and why: (a) Ni; (b) F<sub>2</sub>; (c) CH<sub>3</sub>OH; (d) Sn; (e) Si; (f) Xe?

**12.95** Of the five major types of crystalline solid, which does each of the following form, and why: (a) SiC; (b) Na<sub>2</sub>SO<sub>4</sub>; (c) SF<sub>6</sub>; (d) cholesterol (C<sub>27</sub>H<sub>45</sub>OH); (e) KCl; (f) BN?

**12.96** Zinc oxide adopts the zinc blende crystal structure (Figure P12.96). How many Zn<sup>2+</sup> ions are in the ZnO unit cell?

**12.97** Calcium sulfide adopts the sodium chloride crystal structure (Figure P12.97). How many S<sup>2-</sup> ions are in the CaS unit cell?

Figure P12.96

Figure P12.97

**12.98** Zinc selenide (ZnSe) crystallizes in the zinc blende structure (see Figure P12.96) and has a density of 5.42 g/cm<sup>3</sup>.

(a) How many Zn and Se ions are in each unit cell?

(b) What is the mass of a unit cell?

(c) What is the volume of a unit cell?

(d) What is the edge length of a unit cell?

**12.99** An element crystallizes in a face-centered cubic lattice, and it has a density of 1.45 g/cm<sup>3</sup>. The edge of its unit cell is 4.52 × 10<sup>-8</sup> cm.

(a) How many atoms are in each unit cell?

(b) What is the volume of a unit cell?

(c) What is the mass of a unit cell?

(d) Calculate an approximate atomic mass for the element.

**12.100** Classify each of the following as a conductor, insulator, or semiconductor: (a) phosphorus; (b) mercury; (c) germanium.

**12.101** Classify each of the following as a conductor, insulator, or semiconductor: (a) carbon (graphite); (b) sulfur; (c) platinum.

**12.102** Predict the effect (if any) of an increase in temperature on the electrical conductivity of (a) antimony; (b) tellurium; (c) bismuth.

**12.103** Predict the effect (if any) of a decrease in temperature on the electrical conductivity of (a) silicon; (b) lead; (c) germanium.

### Problems in Context

**12.104** Polonium, the Period 6 member of Group 6A(16), is a rare radioactive metal that is the only element with a crystal structure based on the simple cubic unit cell. If its density is 9.142 g/cm<sup>3</sup>, calculate an approximate atomic radius for polonium.

**12.105** The coinage metals—copper, silver, and gold—crystallize in a cubic closest packed structure. Use the density of copper (8.95 g/cm<sup>3</sup>) and its molar mass (63.55 g/mol) to calculate an approximate atomic radius for copper.

**12.106** One of the most important enzymes in the world—nitrogenase, the plant protein that catalyzes nitrogen fixation—contains active clusters of iron, sulfur, and molybdenum atoms. Crystalline molybdenum (Mo) has a body-centered cubic unit cell ( $d$  of Mo = 10.28 g/cm<sup>3</sup>). (a) Determine the edge length of the unit cell. (b) Calculate the atomic radius of Mo.

**12.107** Tantalum (Ta;  $d$  = 16.634 g/cm<sup>3</sup> and  $\mathcal{M}$  = 180.9479 g/mol) has a body-centered cubic structure with a unit-cell edge length of 3.3058 Å. Use these data to calculate Avogadro's number.

### Advanced Materials

#### Concept Review Questions

**12.108** When tin is added to copper, the resulting alloy (bronze) is much harder than copper. Explain.

**12.109** In the process of doping a semiconductor, certain impurities are added to increase the electrical conductivity. Explain this process for an n-type and a p-type semiconductor.

**12.110** State two molecular characteristics of substances that typically form liquid crystals. How is each related to function?

**12.111** Distinguish between isotropic and anisotropic substances. To which category do liquid crystals belong?

**12.112** How are the properties of high-tech ceramics the same as those of traditional clay ceramics, and how are they different? Refer to specific substances in your answer.

**12.113** Why is the average molar mass of a polymer sample different from the molar mass of an individual chain?

**12.114** How does the random coil shape relate to the radius of gyration of a polymer chain?

**12.115** What factor(s) influence the viscosity of a polymer solution? What factor(s) influence the viscosity of a molten polymer? What is a polymer glass?

**12.116** Use an example to show how branching and crosslinking can affect the physical behavior of a polymer.

#### Skill-Building Exercises (grouped in similar pairs)

**12.117** Silicon and germanium are both semiconducting elements from Group 4A(14) that can be doped to improve their conductivity. Would each of the following form an n-type or a p-type semiconductor: (a) Ge doped with P; (b) Si doped with In?

**12.118** Would each of the following form an n-type or a p-type semiconductor: (a) Ge doped with As; (b) Si doped with B?

**12.119** The repeat unit of the polystyrene of a coffee cup has the formula C<sub>6</sub>H<sub>5</sub>CHCH<sub>2</sub>. If the molar mass of the polymer is 3.5 × 10<sup>5</sup> g/mol, what is the degree of polymerization?

**12.120** The monomer of poly(vinyl chloride) has the formula C<sub>2</sub>H<sub>3</sub>Cl. If there are 1565 repeat units in a single chain of the polymer, what is the molecular mass (in amu) of that chain?

**12.121** The polypropylene (repeat unit CH<sub>3</sub>CHCH<sub>2</sub>) in a plastic toy has a molar mass of 2.8 × 10<sup>5</sup> g/mol, and the length of a repeat unit is 0.252 pm. Calculate the radius of gyration.

**12.122** The polymer that is used to make 2-L soda bottles [poly(ethylene terephthalate)] has a repeat unit with molecular formula C<sub>10</sub>H<sub>8</sub>O<sub>4</sub> and a length of 1.075 nm. Calculate the radius of gyration of a chain with a molar mass of 2.30 × 10<sup>4</sup> g/mol.

## Comprehensive Problems

**12.123** A 0.75-L bottle is cleaned, dried, and closed in a room where the air is 22°C and has 44% relative humidity (that is, the water vapor in the air is 0.44 of the equilibrium vapor pressure at 22°C). The bottle is then brought outside and stored at 0.0°C.

- (a) What mass of liquid water condenses inside the bottle?  
 (b) Would liquid water condense at 10°C? (See Table 5.2.)

**12.124** In an experiment, 5.00 L of N<sub>2</sub> is saturated with water vapor at 22°C and then compressed to half its volume at constant *T*.

- (a) What is the partial pressure of H<sub>2</sub>O in the compressed gas mixture? (b) What mass of water vapor condenses to liquid?

**12.125** Barium is the largest nonradioactive alkaline earth metal. It has a body-centered cubic unit cell and a density of 3.62 g/cm<sup>3</sup>. What is the atomic radius of barium? (Volume of a sphere:  $V = \frac{4}{3}\pi r^3$ .)

**12.126** Two important characteristics used to evaluate the risk of fire or explosion are a compound's *lower flammable limit* (LFL) and *flash point*. The LFL is the minimum percentage by volume in air that is ignitable. Below that, the mixture is too "lean" to burn. The flash point is the temperature at which the air over a confined liquid becomes ignitable. *n*-Hexane boils at 68.7°C at 1 atm. At 20.0°C, its vapor pressure is 121 mmHg. The LFL of *n*-hexane is 1.1%. Calculate the flash point of *n*-hexane.

**12.127** Bismuth is used to calibrate instruments employed in high-pressure studies because it has several well-characterized crystalline phases. Its phase diagram (right) shows the liquid phase and five solid phases that are stable above 1 katm (1000 atm) and up to 300°C.

- (a) Which solid phases are stable at 25°C? (b) Which phase is stable at 50 katm and 175°C? (c) As the pressure is reduced from 100 to 1 katm at 200°C, what phase transitions does bismuth undergo? (d) What phases are present at each of the triple points?

**12.128** In making computer chips, a 4.00-kg cylindrical ingot of ultrapure n-type doped silicon that is 5.20 inches in diameter is sliced into wafers  $1.12 \times 10^{-4}$  m thick.

- (a) Assuming no waste, how many wafers can be made?  
 (b) What is the mass of a wafer (*d* of Si = 2.34 g/cm<sup>3</sup>; *V* of a cylinder =  $\pi r^2 h$ )?  
 (c) A key step in making p-n junctions for the chip is chemical removal of the oxide layer on the wafer through treatment with gaseous HF. Write a balanced equation for this reaction.  
 (d) If 0.750% of the Si atoms are removed during the treatment in part (c), how many moles of HF are required per wafer, assuming 100% reaction yield?

**12.129** Methyl salicylate, C<sub>8</sub>H<sub>8</sub>O<sub>3</sub>, the odorous constituent of oil of wintergreen, has a vapor pressure of 1.00 torr at 54.3°C and 10.0 torr at 95.3°C. (a) What is its vapor pressure at 25°C? (b) What is the minimum number of liters of air that must pass over a sample of the compound at 25°C to vaporize 1.0 mg of it?

**12.130** Mercury (Hg) vapor is toxic and readily absorbed from the lungs. At 20.°C, mercury ( $\Delta H_{\text{vap}} = 59.1$  kJ/mol) has a vapor pressure of  $1.20 \times 10^{-3}$  torr, which is high enough to be hazardous. To reduce the danger to workers in processing plants, Hg is cooled to lower its vapor pressure. At what temperature would the vapor pressure of Hg be at the safer level of  $5.0 \times 10^{-5}$  torr?

**12.131** Polytetrafluoroethylene (Teflon) has a repeat unit with the formula F<sub>2</sub>C—CF<sub>2</sub>. A sample of the polymer consists of fractions with the following distribution of chains:

Fraction	Average Number of Repeat Units	Amount (mol) of Polymer
1	273	0.10
2	330	0.40
3	368	1.00
4	483	0.70
5	525	0.30
6	575	0.10

- (a) Determine the molar mass of each fraction.  
 (b) Determine the number-average molar mass of the sample.  
 (c) Another type of average molar mass of a polymer sample is called the *weight-average molar mass*,  $\mathcal{M}_w$ :

$$\mathcal{M}_w = \frac{\Sigma(\mathcal{M} \text{ of fraction} \times \text{mass of fraction})}{\text{total mass of all fractions}}$$

Calculate the weight-average molar mass of the sample of polytetrafluoroethylene.

**12.132** A greenhouse contains 256 m<sup>3</sup> of air at a temperature of 26°C, and a humidifier in it vaporizes 4.20 L of water. (a) What is the pressure of water vapor in the greenhouse, assuming that none escapes and that the air was originally completely dry (*d* of H<sub>2</sub>O = 1.00 g/mL)? (b) What total volume of liquid water would have to be vaporized to saturate the air (that is, achieve 100% relative humidity)? (See Table 5.2.)

**12.133** Like most transition metals, tantalum (Ta) exhibits several oxidation states. Give the formula of each tantalum compound whose unit cell is depicted below:

**12.134** KF has the same type of crystal structure as NaCl. The unit cell of KF has an edge length of 5.39 Å. Find the density of KF.

**12.135** Furfural, which is prepared from corncobs, is an important solvent in synthetic rubber manufacturing, and it is reduced to furfuryl alcohol, which is used to make polymer resins. Furfural can also be oxidized to 2-furoic acid.

- (a) Which of these compounds can form H bonds? Draw structures in each case.

(b) The molecules of some substances can form an "internal" H bond, that is, an H bond *within* a molecule. This takes the form of a polygon with atoms as corners and bonds as sides and an H bond as one of the sides. Which of these molecules is (are) likely to form a stable internal H bond? Draw the structure. (*Hint*: Structures with 5 or 6 atoms as corners are most stable.)

**12.136** On a humid day in New Orleans, the temperature is 22.0°C, and the partial pressure of water vapor in the air is 31.0 torr. The 9000-ton air-conditioning system in the Louisiana Superdome maintains the inside air temperature at the same 22.0°C, but produces a partial pressure of water vapor of 10.0 torr. The volume of air in the dome is  $2.4 \times 10^6 \text{ m}^3$ , and the total pressure is 1.0 atm both inside and outside the dome.

(a) What mass of water (in metric tons) must be removed every time the inside air is completely replaced with outside air? (*Hint*: How many moles of gas are in the dome? How many moles of water vapor? How many moles of dry air? How many moles of outside air must be added to the air in the dome to simulate the composition of outside air?)

(b) Find the heat released when this mass of water condenses.

**12.137** The boiling point of amphetamine,  $\text{C}_9\text{H}_{13}\text{N}$ , is 201°C at 760 torr and 83°C at 13 torr. What is the concentration (in  $\text{g}/\text{m}^3$ ) of amphetamine when it is in contact with 20.°C air?

**12.138** Diamond has a face-centered cubic unit cell, with four more C atoms in tetrahedral holes within the cell. Densities of diamonds vary from  $3.01 \text{ g}/\text{cm}^3$  to  $3.52 \text{ g}/\text{cm}^3$  because C atoms are missing from some holes. (a) Calculate the unit-cell edge length of the densest diamond. (b) Assuming the cell dimensions are fixed, how many C atoms are in the unit cell of the diamond with the lowest density?

**12.139** Is it possible for a salt of formula  $\text{AB}_3$  to have a face-centered cubic unit cell of anions with cations in all eight of the available holes? Explain.

**12.140** The density of solid gallium at its melting point is  $5.9 \text{ g}/\text{cm}^3$ , whereas that of liquid gallium is  $6.1 \text{ g}/\text{cm}^3$ . Is the temperature at the triple point higher or lower than the normal melting point? Is the slope of the solid-liquid line for gallium positive or negative?

**12.141** A 4.7-L sealed bottle containing 0.33 g of liquid ethanol,  $\text{C}_2\text{H}_6\text{O}$ , is placed in a refrigerator and reaches equilibrium with its vapor at  $-11^\circ\text{C}$ . (a) What mass of ethanol is present in the vapor? (b) When the container is removed and warmed to room temperature, 20.°C, will all the ethanol vaporize? (c) How much liquid ethanol would be present at 0.0°C? The vapor pressure of ethanol is 10. torr at  $-2.3^\circ\text{C}$  and 40. torr at  $19^\circ\text{C}$ .

**12.142** Substance A has the following properties.

mp at 1 atm:	$-20.^\circ\text{C}$	bp at 1 atm:	$85.^\circ\text{C}$
$\Delta H_{\text{fus}}$ :	180. J/g	$\Delta H_{\text{vap}}$ :	500. J/g
$c_{\text{solid}}$ :	$1.0 \text{ J}/\text{g}\cdot^\circ\text{C}$	$c_{\text{liquid}}$ :	$2.5 \text{ J}/\text{g}\cdot^\circ\text{C}$
$c_{\text{gas}}$ :	$0.5 \text{ J}/\text{g}\cdot^\circ\text{C}$		

At 1 atm, a 25-g sample of A is heated from  $-40.^\circ\text{C}$  to  $100.^\circ\text{C}$  at a constant rate of 450. J/min. (a) How many minutes does it take to heat the sample to its melting point? (b) How many minutes does it take to melt the sample? (c) Perform any other necessary calculations, and draw a curve of temperature vs. time for the entire heating process.

**12.143** An aerospace manufacturer is building a prototype experimental aircraft that cannot be detected by radar. Boron nitride is chosen for incorporation into the body parts, and the boric acid/ammonia method is used to prepare the ceramic material. Given 85.5% and 86.8% yields for the two reaction steps, how much boron nitride can be prepared from 1.00 metric ton of boric acid

and  $12.5 \text{ m}^3$  of ammonia at 275 K and  $3.07 \times 10^3 \text{ kPa}$ ? Assume that ammonia does not behave ideally under these conditions and is recycled completely in the reaction process.

**12.144** The ball-and-stick models below represent three compounds with the same molecular formula,  $\text{C}_4\text{H}_8\text{O}_2$ :

(a) Which compound(s) can form intermolecular H bonds?

(b) Which has the highest viscosity?

**12.145** The  $\Delta H_{\text{f}}^\circ$  of gaseous dimethyl ether ( $\text{CH}_3\text{OCH}_3$ ) is  $-185.4 \text{ kJ}/\text{mol}$ ; the vapor pressure is 1.00 atm at  $-23.7^\circ\text{C}$  and 0.526 atm at  $-37.8^\circ\text{C}$ . (a) Calculate  $\Delta H_{\text{vap}}^\circ$  of dimethyl ether. (b) Calculate  $\Delta H_{\text{f}}^\circ$  of liquid dimethyl ether.

**12.146** The crystal structure of sodium is based on the body-centered cubic unit cell. What is the mass of one unit cell of Na?

**12.147** The *intrinsic viscosity* of a polymer solute in a solvent,  $[\eta]_{\text{solvent}}$ , is the portion of the total viscosity due to the solute and is related to solute shape. It has also been found to relate to intermolecular interactions between solvent and polymer: higher  $[\eta]_{\text{solvent}}$  means stronger interaction. The  $[\eta]_{\text{solvent}}$  values of polymers in solution are given by the Mark-Houwink equation,  $[\eta]_{\text{solvent}} = K \mathcal{M}^a$ , where  $\mathcal{M}$  is the molar mass of the polymer and  $K$  and  $a$  are constants specific to the polymer and solvent. Use the data below for substances at  $25^\circ\text{C}$  to answer the following questions:

Polymer	Solvent	$K (\text{mL}/\text{g})$	$a$
Polystyrene	Benzene	$9.5 \times 10^{-3}$	0.74
	Cyclohexane	$8.1 \times 10^{-2}$	0.50
Polyisobutylene	Benzene	$8.3 \times 10^{-2}$	0.50
	Cyclohexane	$2.6 \times 10^{-1}$	0.70

(a) A polystyrene sample has a molar mass of 104,160 g/mol. Calculate the intrinsic viscosity of this polymer in benzene and in cyclohexane. Which solvent has stronger interactions with the polymer?

(b) A different polystyrene sample has a molar mass of 52,000 g/mol. Calculate its  $[\eta]_{\text{benzene}}$ . Given a polymer standard of known  $\mathcal{M}$ , how could you use its measured  $[\eta]$  in a given solvent to determine the molar mass of any sample of that polymer?

(c) Compare  $[\eta]$  values of a polyisobutylene sample [repeat unit  $(\text{CH}_3)_2\text{CCH}_2$ ] with a molar mass of 104,160 g/mol with those of the polystyrene in part (a). What does this suggest about the solvent-polymer interactions of the two samples?

**12.148** One way of purifying gaseous  $\text{H}_2$  is to pass it under high pressure through the holes of a metal's crystal structure. Palladium, which adopts a cubic closest packed structure, absorbs more  $\text{H}_2$  than any other element and is one of the metals used for this purpose. How the metal and  $\text{H}_2$  interact is unclear, but it is estimated that the density of absorbed  $\text{H}_2$  approaches that of liquid hydrogen (70.8 g/L). What volume (in L) of gaseous  $\text{H}_2$  (at STP) can be packed into the spaces of  $1 \text{ dm}^3$  of palladium metal?

## Concepts and Skills to Review Before You Study This Chapter

- › separation of mixtures (Section 2.9)
- › calculations involving mass percent (Section 3.1) and molarity (Section 4.1)
- › electrolytes; water as solvent (Sections 4.1 and 12.5)
- › mole fraction and Dalton's law (Section 5.4)
- › intermolecular forces and polarizability (Section 12.3)
- › monomers and polymers (Section 12.7)
- › equilibrium nature of phase changes and vapor pressure of liquids; phase diagrams (Section 12.2)

Virtually all the gases, liquids, and solids in the real world are mixtures—two or more substances mixed together physically, not combined chemically. Synthetic mixtures usually contain only a dozen or so components; for example, the soda you may be drinking while reading your chemistry text contains water, carbon dioxide, sugar, caffeine, caramel color, phosphoric and citric acids, and other flavorings. Natural mixtures, such as seawater and soil, often contain over 50 components. Living mixtures, such as trees and students, are the most complex—even a simple bacterial cell contains nearly 6000 different compounds (Table 13.1).

Recall from Chapter 2 that a mixture has two defining characteristics: *its composition is variable*, and *it retains some properties of its components*. We focus here on two common types of mixtures—solutions and colloids—whose main differences relate to particle size and number of phases:

- A *solution* is a *homogeneous* mixture; that is, it exists as one phase. In a solution, the particles are individual atoms, ions, or small molecules.
- A *colloid* is a type of *heterogeneous* mixture. A heterogeneous mixture has two or more phases. They may be visibly distinct, like pebbles in concrete, or not, like the much smaller particles in the colloids smoke and milk. In a colloid, the particles are typically macromolecules or aggregations of small molecules that are dispersed so finely they don't settle out.

**IN THIS CHAPTER . . .** We focus on how intermolecular forces and other energy considerations affect a solute dissolving in a solvent, how to calculate concentration, and how solutions differ from pure substances. We also briefly consider the behavior and applications of colloids.

- › We survey intermolecular forces between solute and solvent and find that substances with similar types of forces form a solution.
- › We see how the dual polarity of some organic molecules gives rise to these same intermolecular forces, and we find that they determine the structures and functions of soaps, antibiotics, biological macromolecules, and cell membranes.
- › We use a stepwise cycle to see why a substance dissolves and examine the heat involved and the dispersal of matter that occurs when a solution forms. To understand the latter factor, we introduce the concept of entropy.
- › We examine the equilibrium nature of solubility and see how temperature and pressure affect it.
- › We define various solution concentration units and see how to interconvert them mathematically.
- › We see why the physical properties of solutions are different from those of pure substances and learn how to apply those differences.
- › We investigate colloids and apply solution and colloid chemistry to the purification of water.

Table 13.1

Approximate Composition of a Bacterium

Substance	Mass % of Cell	Number of Types	Number of Molecules
Water	~70	1	$5 \times 10^{10}$
Ions	1	20	?
Sugars*	3	200	$3 \times 10^8$
Amino acids*	0.4	100	$5 \times 10^7$
Lipids*	2	50	$3 \times 10^7$
Nucleotides*	0.4	200	$1 \times 10^7$
Other small molecules	0.2	~200	?
Macromolecules (proteins, nucleic acids, polysaccharides)	23	~5000	$6 \times 10^6$

\*Includes precursors and metabolites.

## 13.1 TYPES OF SOLUTIONS: INTERMOLECULAR FORCES AND SOLUBILITY

A **solute** dissolves in a **solvent** to form a solution. In general, *the solvent is the most abundant component*, but in some cases, the substances are **miscible**—soluble in each other in any proportion—so the terms “solute” and “solvent” lose their meaning. *The physical state of the solvent usually determines the physical state of the solution.* Solutions can be gaseous, liquid, or solid, but we focus mostly on liquid solutions because they are by far the most important.

The **solubility** ( $S$ ) of a solute is the maximum amount that dissolves in a fixed quantity of a given solvent at a given temperature, when an excess of the solute is present. Different solutes have different solubilities:

- Sodium chloride (NaCl),  $S = 39.12 \text{ g}/100. \text{ mL water at } 100.^{\circ}\text{C}$
- Silver chloride (AgCl),  $S = 0.0021 \text{ g}/100. \text{ mL water at } 100.^{\circ}\text{C}$

Solubility is a *quantitative* term, but *dilute* and *concentrated* are qualitative, referring to the *relative* amounts of dissolved solute:

- The NaCl solution above is concentrated (a relatively large amount of solute dissolved in a given quantity of solvent).
- The AgCl solution is dilute (a relatively small amount of solute in a given quantity of solvent).

A given solute may dissolve in one solvent and not another. The explanation lies in the relative strengths of the intermolecular forces within both solute and solvent and between them. The useful rule-of-thumb “**like dissolves like**” says that *substances with similar types of intermolecular forces dissolve in each other.* Thus, by knowing the forces, we can often predict whether a solute will dissolve in a solvent.

### Intermolecular Forces in Solution

All the intermolecular forces we discussed for pure substances also occur in solutions (Figure 13.1; also see Section 12.3):

1. *Ion-dipole forces* (attractions between ions and polar molecules) are the principal force involved when an ionic compound dissolves in water. Two events occur simultaneously:

- *Forces compete.* When a soluble salt is added to water, each type of ion attracts the oppositely charged pole of a water molecule. These attractions between ions and water compete with and overcome attractions between the ions, and the crystal structure breaks down.
- *Hydration shells form.* As an ion separates from the crystal structure, water molecules cluster around it in **hydration shells**. The number of water molecules in the innermost shell depends on the ion’s size: four fit tetrahedrally around small ions like  $\text{Li}^+$ , while the larger  $\text{Na}^+$  and  $\text{F}^-$  have six water molecules surrounding them octahedrally (Figure 13.2). In the innermost shell, normal hydrogen bonding between water molecules is disrupted to form the ion-dipole forces. But these water molecules are H bonded to others in the next shell, and those are H bonded to others still farther away.

2. *Hydrogen bonding* (attractions between molecules with an H atom bonded to N, O, or F) is the principal force in solutions of polar, O- and N-containing organic and biological compounds, such as alcohols, amines, and amino acids.

3. *Dipole-dipole forces* (attractions between polar molecules), in the absence of H bonding, allow polar molecules like propanal ( $\text{CH}_3\text{CH}_2\text{CHO}$ ) to dissolve in polar solvents like dichloromethane ( $\text{CH}_2\text{Cl}_2$ ).

4. **Ion-induced dipole forces**, one type of *charge-induced dipole force*, rely on polarizability. They arise when an ion’s charge distorts the electron cloud of a nearby nonpolar molecule, giving it a temporary dipole moment. This type of force initiates the binding of the  $\text{Fe}^{2+}$  ion in hemoglobin to an  $\text{O}_2$  molecule that enters a red blood cell.

**Figure 13.1** Types of intermolecular forces in solutions. Forces are listed in order of decreasing strength (values are in kJ/mol), with an example of each.

**Figure 13.2** Hydration shells around an  $\text{Na}^+$  ion. Ion-dipole forces orient water molecules around an ion. In the innermost shell here, six water molecules surround the cation octahedrally.

- Dipole-induced dipole forces**, also based on polarizability, arise when a polar molecule distorts the electron cloud of a nonpolar molecule. They are weaker than ion-induced dipole forces because the charge of each pole is less than an ion's (Coulomb's law). The solubility in water of atmospheric  $\text{O}_2$ ,  $\text{N}_2$ , and noble gases, while limited, is due in part to these forces. Paint thinners and grease solvents also rely on them.
- Dispersion forces* contribute to the solubility of all solutes in all solvents, but they are the *principal* intermolecular force in solutions of nonpolar substances, such as petroleum and gasoline.

The same forces maintain the shapes of biological macromolecules (Section 13.2).

## Liquid Solutions and the Role of Molecular Polarity

From cytoplasm to tree sap, gasoline to cleaning fluid, iced tea to urine, liquid solutions are very familiar. Water is the most prominent solvent, but there are many other liquid solvents, with polarities from very polar to nonpolar.

**Applying the Like-Dissolves-Like Rule** The like-dissolves-like rule says that when the forces *within* the solute are *similar* to those *within* the solvent, the forces can *replace* each other and a solution forms. Thus,

- Salts are soluble in water* because the ion-dipole attractions between ion and water are similar in strength to the strong attractions between the ions and the strong H bonds between water molecules, so they *can* replace each other.
- Salts are insoluble in hexane* ( $\text{C}_6\text{H}_{14}$ ) because the ion-induced dipole forces between ion and nonpolar hexane are very weak and *cannot* replace the strong attractions between the ions.
- Oil is insoluble in water* because the weak dipole-induced dipole forces between oil and water molecules *cannot* replace the strong H bonds between water molecules or the extensive dispersion forces within the oil.
- Oil is soluble in hexane* because dispersion forces in one *can* replace the similar dispersion forces in the other.

**Dual Polarity and Effects on Solubility** To examine these ideas further, let's compare the solubilities of a series of alcohols in water and in hexane ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$ ), two solvents with very different intermolecular forces; polar water molecules exhibit H bonds, while nonpolar hexane molecules have dispersion forces. Alcohols are organic compounds that have a dual polarity, a polar hydroxyl ( $-\text{OH}$ ) group bonded to a nonpolar hydrocarbon group:

- The  $-\text{OH}$  portion interacts through strong H bonds with water and through weak dipole-induced dipole forces with hexane.
- The hydrocarbon portion interacts through dispersion forces with hexane and through very weak dipole-induced dipole forces with water.

Table 13.2

Solubility\* of a Series of Alcohols in Water and in Hexane

Alcohol	Model	Solubility in Water	Solubility in Hexane
CH <sub>3</sub> OH (methanol)		∞	1.2
CH <sub>3</sub> CH <sub>2</sub> OH (ethanol)		∞	∞
CH <sub>3</sub> (CH <sub>2</sub> ) <sub>2</sub> OH (1-propanol)		∞	∞
CH <sub>3</sub> (CH <sub>2</sub> ) <sub>3</sub> OH (1-butanol)		1.1	∞
CH <sub>3</sub> (CH <sub>2</sub> ) <sub>4</sub> OH (1-pentanol)		0.30	∞
CH <sub>3</sub> (CH <sub>2</sub> ) <sub>5</sub> OH (1-hexanol)		0.058	∞

\*Expressed in mol alcohol/1000 g solvent at 20°C.

The general formula for an alcohol is CH<sub>3</sub>(CH<sub>2</sub>)<sub>n</sub>OH, and we'll look at straight-chain examples with one to six carbons ( $n = 0$  to 5):

1. *Solubility in water is high for smaller alcohols.* From the models in Table 13.2, we see that the —OH group is a relatively large portion of the alcohols with one to three carbons ( $n = 0$  to 2). These molecules interact with each other through H bonding, just as water molecules do. When they mix with water, H bonding *within* solute and *within* solvent is replaced by H bonding *between* solute and solvent (Figure 13.3). As a result, these smaller alcohols are miscible with water.

2. *Solubility in water is low for larger alcohols.* Solubility decreases dramatically for alcohols larger than three carbons ( $n > 2$ ); in fact, those with chains longer than six carbons ( $n > 5$ ) are insoluble in water. For larger alcohols to dissolve, the nonpolar chains have to move among the water molecules, replacing the strong H-bond attractions between water molecules with the weak attractions of the chains for water. While the —OH portion of such an alcohol forms H bonds to water, these cannot make up for all the other H bonds between water molecules that have to break to make room for the long hydrocarbon portion.

Table 13.2 shows that the opposite trend occurs with hexane:

1. *Solubility in hexane is low for the smallest alcohol.* For alcohols in hexane, in addition to dispersion forces, weak dipole-induced dipole forces exist between the —OH of methanol (CH<sub>3</sub>OH) and hexane. These cannot replace the strong H bonding between CH<sub>3</sub>OH molecules, so solubility is relatively low.

2. *Solubility in hexane is high for larger alcohols.* In any larger alcohol ( $n > 0$ ), dispersion forces between the hydrocarbon portion and hexane *can* replace dispersion forces between hexane molecules. With only weak forces within the solvent to be replaced, even ethanol, with a two-carbon chain, has enough dispersion forces between it and hexane to be miscible.

In pure water, H bonds link the molecules.

In pure methanol, H bonds link the molecules.

In a solution of water and methanol, H bonds link the two types of molecules.

Figure 13.3 Like dissolves like: solubility of methanol in water.

Many organic molecules have polar and nonpolar portions, which determine their solubility. For example, carboxylic acids and amines behave like alcohols: methanoic acid (HCOOH, formic acid) and methanamine (CH<sub>3</sub>NH<sub>2</sub>) are miscible with water and slightly soluble in hexane, whereas hexanoic acid [CH<sub>3</sub>(CH<sub>2</sub>)<sub>4</sub>COOH] and 1-hexanamine [CH<sub>3</sub>(CH<sub>2</sub>)<sub>5</sub>NH<sub>2</sub>] are slightly soluble in water and very soluble in hexane.

## SAMPLE PROBLEM 13.1

## Predicting Relative Solubilities

**Problem** Predict which solvent will dissolve more of the given solute:

- (a) Sodium chloride in methanol (CH<sub>3</sub>OH) or in 1-propanol (CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>OH)  
 (b) Ethylene glycol (HOCH<sub>2</sub>CH<sub>2</sub>OH) in hexane (CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub>) or in water  
 (c) Diethyl ether (CH<sub>3</sub>CH<sub>2</sub>OCH<sub>2</sub>CH<sub>3</sub>) in water or in ethanol (CH<sub>3</sub>CH<sub>2</sub>OH)

**Plan** We examine the formulas of solute and solvent to determine the forces in and between solute and solvent. A solute is more soluble in a solvent whose intermolecular forces are similar to, and therefore can replace, its own.

**Solution (a) Methanol.** NaCl is ionic, so it dissolves through ion-dipole forces. Both methanol and 1-propanol have a polar —OH group, but the hydrocarbon portion of each alcohol interacts only weakly with the ions and 1-propanol has a longer hydrocarbon portion than methanol.

**(b) Water.** Ethylene glycol molecules have two —OH groups, so they interact with each other through H bonding. H bonds formed with H<sub>2</sub>O can replace these H bonds between solute molecules better than dipole-induced dipole forces with hexane can.

**(c) Ethanol.** Diethyl ether molecules interact through dipole-dipole and dispersion forces. They can form H bonds to H<sub>2</sub>O or to ethanol. But ethanol can also interact with the ether effectively through dispersion forces because it has a hydrocarbon chain.

## FOLLOW-UP PROBLEMS

*Brief Solutions for all Follow-up Problems appear at the end of the chapter.*

**13.1A** State which solute is more soluble in the given solvent and which forces are most important: (a) 1-butanol (CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OH) or 1,4-butanediol (HOCH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OH) in water; (b) chloroform (CHCl<sub>3</sub>) or carbon tetrachloride (CCl<sub>4</sub>) in water.

**13.1B** State which solvent can dissolve more of the given solute and which forces are most important: (a) chloromethane (CH<sub>3</sub>Cl) in chloroform (CHCl<sub>3</sub>) or in methanol (CH<sub>3</sub>OH); (b) pentanol (C<sub>5</sub>H<sub>11</sub>OH) in water or in hexane (C<sub>6</sub>H<sub>14</sub>).

**SOME SIMILAR PROBLEMS** 13.13 and 13.14

**Gas-Liquid Solutions** A substance with very weak intermolecular attractions should have a low boiling point and, thus, would be a gas under ordinary conditions. Also, it would not be very soluble in water because of weak solute-solvent forces. Thus, for nonpolar or slightly polar gases, boiling point generally correlates with solubility in water (Table 13.3). A higher boiling point is an indication of stronger intermolecular forces, which result in a greater solubility in water.

The small amount of a nonpolar gas that *does* dissolve may be vital. At 25°C and 1 atm, the solubility of O<sub>2</sub> is only 3.2 mL/100. mL of water, but aquatic animal life requires it. At times, the solubility of a nonpolar gas may *seem* high because it is also *reacting* with the solvent. Oxygen seems more soluble in blood than in water because it bonds chemically to hemoglobin in red blood cells. Carbon dioxide, which is essential for aquatic plants and coral-reef growth, seems very soluble in water (~81 mL of CO<sub>2</sub>/100. mL of H<sub>2</sub>O at 25°C and 1 atm) because it is dissolving *and* reacting:

## Gas Solutions and Solid Solutions

Gas solutions and solid solutions also have vital importance and numerous applications.

**Gas-Gas Solutions** All gases are miscible with each other. Air is the classic example of a gaseous solution, consisting of about 18 gases in widely differing proportions.

## Correlation Between Boiling Point and Solubility in Water

Table 13.3

Gas	Solubility (mol/L)*	bp (K)
He	4.2 × 10 <sup>-4</sup>	4.2
Ne	6.6 × 10 <sup>-4</sup>	27.1
N <sub>2</sub>	10.4 × 10 <sup>-4</sup>	77.4
CO	15.6 × 10 <sup>-4</sup>	81.6
O <sub>2</sub>	21.8 × 10 <sup>-4</sup>	90.2
NO	32.7 × 10 <sup>-4</sup>	121.4

\*At 273 K and 1 atm.

**Figure 13.4** The arrangement of atoms in two types of alloys.

Source: (A) © Ruth Melnick; (B) © Ingram Publishing/age fotostock RF

Anesthetic gas proportions are finely adjusted to the needs of the patient and the length of the surgical procedure. The proportions of many industrial gas mixtures, such as  $\text{CO}/\text{H}_2$  in syngas production or  $\text{N}_2/\text{H}_2$  in ammonia production, are controlled to optimize product yield under varying conditions of temperature and pressure.

**Gas-Solid Solutions** When a gas dissolves in a solid, it occupies the spaces between the closely packed particles. Hydrogen gas can be purified by passing an impure sample through palladium. Only  $\text{H}_2$  molecules are small enough to fit between the Pd atoms, where they form Pd—H bonds. The H atoms move from one Pd atom to another and emerge from the metal as  $\text{H}_2$  molecules (see Figure 14.2).

The ability of gases to dissolve in a solid also has disadvantages. The electrical conductivity of copper is greatly reduced by the presence of  $\text{O}_2$ , which dissolves into the crystal structure and reacts to form copper(I) oxide. High-conductivity copper is prepared by melting and recasting the metal in an  $\text{O}_2$ -free atmosphere.

**Solid-Solid Solutions** Solids diffuse so little that their mixtures are usually heterogeneous. Some solid-solid solutions can be formed by melting the solids and then mixing them and allowing them to freeze. Many **alloys**, mixtures of elements that have a metallic character, are solid-solid solutions (although several have microscopic heterogeneous regions). Alloys generally fall into one of two categories:

- In a *substitutional alloy* like brass (Figure 13.4A), atoms of zinc *replace* atoms of the main element, copper, at some sites in the cubic closest packed array. This occurs when the atoms of the elements in the alloy are similar in size.
- In an *interstitial alloy* like carbon steel (Figure 13.4B), atoms of carbon (a nonmetal is typical in this type of alloy) *fill some spaces (interstices)* between atoms of the main element, iron, in the body-centered array.

Waxes are also solid-solid solutions. Most are amorphous solids with some small regions of crystalline regularity. A *wax* is defined as a solid of biological origin that is insoluble in water and soluble in nonpolar solvents. Beeswax, which bees secrete to build their combs, is a homogeneous mixture of fatty acids, long-chain carboxylic acids, and hydrocarbons in which some of the molecules are more than 40 carbon atoms long. Carnauba wax, from a South American palm, is a mixture of compounds, each consisting of a fatty acid bound to a long-chain alcohol. It is hard but forms a thick gel in nonpolar solvents, so it is perfect for waxing cars.

### › Summary of Section 13.1

- › A solution is a homogeneous mixture of a solute dissolved in a solvent through the action of intermolecular forces.
- › Ion-dipole, ion-induced dipole, and dipole-induced dipole forces occur in solutions, in addition to all the intermolecular forces that also occur in pure substances.
- › If similar intermolecular forces occur in solute and solvent, they replace each other when the substances mix and a solution is likely to form (the like-dissolves-like rule).
- › When ionic compounds dissolve in water, the ions become surrounded by hydration shells of H-bonded water molecules.

- › Solubility of organic molecules in various solvents depends on the relative sizes of their polar and nonpolar portions.
- › The solubility of nonpolar gases in water is low because of weak intermolecular forces. Gases are miscible with one another and dissolve in solids by fitting into spaces in the crystal structure.
- › Solid-solid solutions include alloys (some of which are formed by mixing molten components) and waxes.

## 13.2 INTERMOLECULAR FORCES AND BIOLOGICAL MACROMOLECULES

We discuss the shapes of proteins, nucleic acids, and cell membranes, as well as the functions of soaps and antibiotics, in this chapter on solutions because they depend on intermolecular forces too. These shapes and functions are explained by two ideas:

- Polar and ionic groups attract water, but nonpolar groups do not.
- Just as separate molecules attract each other, so do distant groups on the same molecule.

### The Structures of Proteins

**Proteins** are very large molecules (called polymers) formed by linking together many smaller molecules called **amino acids**; about 20 different amino acids occur in proteins, which range in size from about 50 amino acids ( $M \approx 5 \times 10^3$  g/mol) to several thousand ( $M \approx 5 \times 10^5$  g/mol). Proteins with a few types of amino acids in repeating patterns have extended helical or sheetlike shapes and give structure to hair, skin, and so forth. Proteins with many types of amino acids have complex, globular shapes and function as antibodies, enzymes, and so forth. Let's see how intermolecular forces among amino acids influence the shapes of globular proteins.

**The Polarity of Amino-Acid Side Chains** In a cell, a free amino acid has four groups bonded to one C, which is called the  $\alpha$ -carbon (Figure 13.5): charged carboxyl ( $-\text{COO}^-$ ) and amine ( $-\text{NH}_3^+$ ) groups, an H atom, and a *side chain*, represented by an R, which ranges from another H atom, to a few C atoms, to a two-ringed  $\text{C}_9\text{H}_8\text{N}$  group. In a protein, the carboxyl group of one amino acid is linked covalently to the amine group of the next by a *peptide bond*. (We discuss amino acid structures and peptide bond formation in Chapter 15.) Thus, as Figure 13.6 shows, the *backbone* of a protein is a polypeptide chain: an  $\alpha$ -carbon connected through a peptide bond (orange screens) to the next  $\alpha$ -carbon, and so forth. The various side chains (gray screens) dangle off the  $\alpha$ -carbons on alternate sides of the chain.

**Figure 13.5** The charged form of an amino acid under physiological conditions.

**Figure 13.6** A portion of a polypeptide chain. Three peptide bonds (orange screens) join four amino acids in this chain portion.

Amino acids can be classified by the polarity or charge of their side chains: nonpolar, polar, and ionic. A few examples are

**Intermolecular Forces and Protein Shape** The same forces that act between separate molecules are responsible for a protein's shape, because *distant groups on the protein chain end up near each other as the chain bends*. Figure 13.7 depicts the forces within a small portion of a protein and between the protein and the aqueous medium of the cell. In general order of importance, they are

- Covalent peptide bonds create the backbone (polypeptide chain).
- Helical and sheetlike segments arise from *H bonds between the C=O of one peptide bond and the N—H of another*.
- Polar and ionic side chains protrude into the surrounding cell fluid, interacting with water through ion-dipole forces and H bonds.
- Nonpolar side chains interact through dispersion forces within the nonaqueous protein interior.

**Figure 13.7** The forces that maintain protein structure. Covalent, ionic, and intermolecular forces act between the parts of a portion of a protein and between the protein and surrounding H<sub>2</sub>O molecules to determine the protein's shape. (Water molecules and some amino-acid side chains are shown as ball-and-stick models within space-filling contours.)

- The —SH ends of two cysteine side chains form a covalent —S—S— bond, a *disulfide bridge*, between distant parts of the chain that creates a loop.
- Oppositely charged ends of ionic side chains, —COO<sup>−</sup> and —NH<sub>3</sub><sup>+</sup> groups, that lie near each other form an electrostatic *salt link* (or *ion pair*) that creates bend in the protein chain.
- Other H bonds between side chains keep distant chain portions near each other.

Thus, *soluble proteins have polar-ionic exteriors and nonpolar interiors*. As we emphasize in Chapter 15, the amino acid *sequence* of a protein determines its *shape*, which determines its *function*.

## Dual Polarity in Soaps, Membranes, and Antibiotics

Dual polarity, which we noted as a key factor in the solubility of alcohols, also helps explain how soaps, cell membranes, and antibiotics function.

**Action of Soaps** A **soap** is the salt formed when a strong base (a metal hydroxide) reacts with a *fatty acid*, a carboxylic acid with a long hydrocarbon chain. A typical soap molecule is made up of a nonpolar “tail” 15–19 carbons long and a polar-ionic “head” consisting of a —COO<sup>−</sup> group and the cation of the strong base. The cation greatly influences a soap’s properties. Lithium soaps are hard and high melting and used in car lubricants. Potassium soaps are low melting and used in liquid form. Several sodium soaps, including sodium stearate, CH<sub>3</sub>(CH<sub>2</sub>)<sub>16</sub>COONa, are components of common bar soaps:

When grease on your hands or clothes is immersed in soapy water, the soap molecules’ nonpolar tails interact with the nonpolar grease molecules through dispersion forces, while the polar-ionic heads attract water molecules through ion-dipole forces and H bonds. Tiny aggregates of grease molecules, embedded with soap molecules whose polar-ionic heads stick into the water, are flushed away by added water (Figure 13.8).

**Figure 13.8** The cleaning ability of a soap depends on the dual polarity of its molecules.

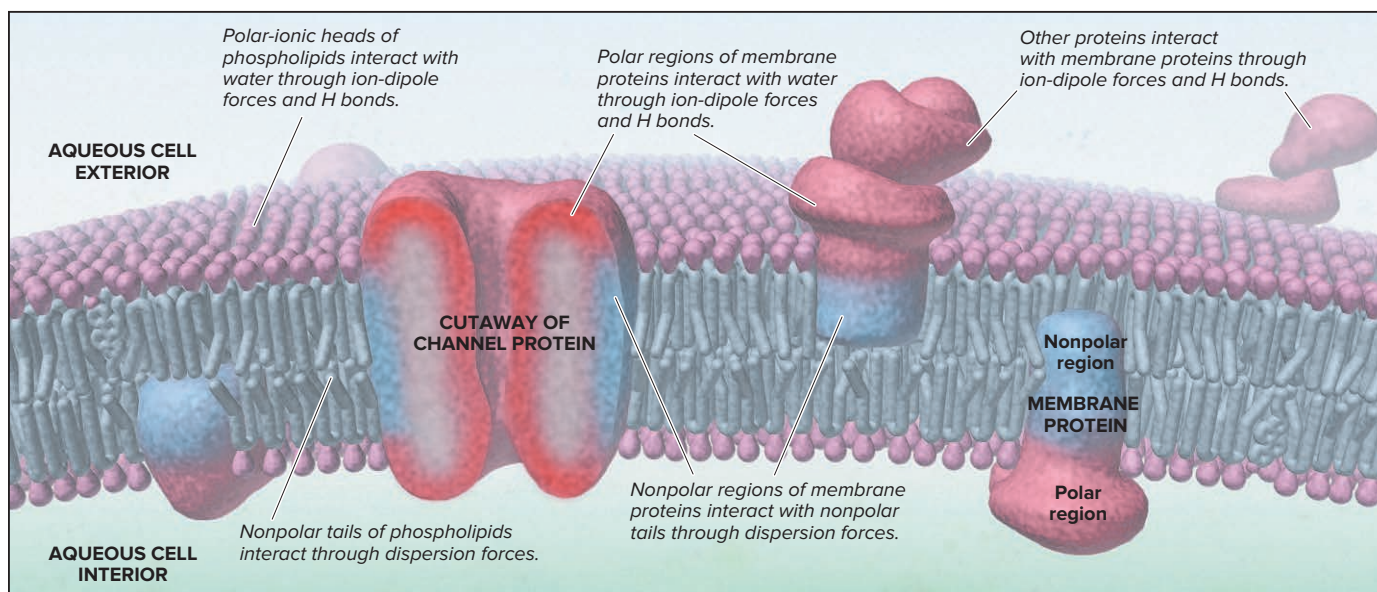

**Figure 13.9** A membrane phospholipid. Lecithin (phosphatidylcholine), a phospholipid, is shown as a space-filling model and as a simplified purple-and-gray shape.

**Lipid Bilayers and the Structure of the Cell Membrane** The most abundant molecules in cell membranes are *phospholipids*. Like soaps, they have a dual polarity—a nonpolar tail consists of two fatty acid chains, and an organophosphate group is the polar-ionic head (Figure 13.9). Remarkably, phospholipids self-assemble in water into a sheetlike double layer called a **lipid bilayer**, with the tails of the two layers touching and the heads in the water. In the laboratory, bilayers form spherical vesicles that trap water inside. These structures are favored energetically because of their intermolecular forces:

- Ion-dipole forces occur between polar heads and water inside and outside.
- Dispersion forces occur between nonpolar tails within the bilayer interior.
- Minimal contact exists between nonpolar tails and water.

A typical animal cell membrane consists of a phospholipid bilayer with proteins partially embedded in it; a small portion of such a membrane appears in Figure 13.10. Membrane proteins, which play countless essential roles, differ fundamentally from soluble proteins in terms of their dual polarity:

- Soluble proteins have polar exteriors and nonpolar interiors. They form ion-dipole and H-bonding forces between water and *polar groups on the exterior* and dispersion forces between *nonpolar groups in the interior* (see Figure 13.7).
- Membrane proteins have exteriors that are partially polar (*red*) and partially nonpolar (*blue*). They have polar groups on the *exterior portion that juts into the aqueous surroundings* and nonpolar groups on the *exterior portion embedded in the membrane*. These nonpolar groups form dispersion forces with the phospholipid tails of the bilayer. Channel proteins also have polar groups lining the aqueous channel.

**Figure 13.10** Intermolecular forces and cell membrane structure.

**Action of Antibiotics** A key function of a cell membrane is to balance internal and external ion concentrations:  $\text{Na}^+$  is excluded from the cell, and  $\text{K}^+$  is kept inside. Gramicidin A and similar antibiotics act by forming channels in the cell membrane of a bacterium through which ions flow (Figure 13.11). Two helical gramicidin A molecules, their nonpolar groups outside and polar groups inside, lie end to end to form a channel through the membrane. The nonpolar outside stabilizes the molecule in the cell membrane through dispersion forces, and the polar inside passes the ions along using ion-dipole forces, like a “bucket brigade.” Over  $10^7$  ions pass through each of these channels per second, which disrupts the vital ion balance, and the bacterium dies.

## The Structure of DNA

The chemical information that guides the design and construction, and therefore the function, of all proteins is contained in **nucleic acids**, unbranched polymers made up

**Figure 13.11** The mode of action of the antibiotic gramicidin A. The  $K^+$  ions are shown leaving the cell. At the same time (not shown),  $Na^+$  ions enter the cell.

of smaller units (monomers) called **mononucleotides**. Each mononucleotide consists of an N-containing base, a sugar, and a phosphate group (Figure 13.12). In DNA (*deoxyribonucleic acid*), the sugar is 2-deoxyribose, in which  $-H$  substitutes for  $-OH$  on the second C atom of the five-C sugar ribose.

The repeating pattern of the DNA chain is *sugar linked to phosphate linked to sugar linked to phosphate*, and so on. Attached to each sugar is one of four N-containing bases, flat ring structures that dangle off the polynucleotide chain, similar to the way amino-acid side chains dangle off the polypeptide chain.

**Intermolecular Forces and the Double Helix** DNA exists as two chains wrapped around each other in a **double helix** that is stabilized by intermolecular forces (Figure 13.13):

- *On the more polar exterior*, negatively charged sugar-phosphate groups interact with the aqueous surroundings via ion-dipole forces and H bonds.
- *In the less polar interior*, flat, N-containing bases stack above each other and interact by dispersion forces.
- *Bases form specific interchain H bonds*; that is, each base in one chain is always H bonded with its complementary base in the other chain. Thus, *the base sequence of one chain is the H-bonded complement of the base sequence of the other*.

**Figure 13.12** A short portion of the polynucleotide chain of DNA.

**Figure 13.13** The double helix of DNA. A segment of DNA (*left*) has its polar-ionic sugar-phosphate portion (*pink*) facing the water and the nonpolar bases (*gray*) stacking in the interior. The expanded portion (*right*) shows an H-bonded pair of the bases guanine and cytosine.

A DNA molecule contains millions of H bonds linking bases in these prescribed pairs. The *total* energy of the H bonds keeps the chains together, but each H bond is weak enough (around 5% of a typical covalent single bond) that a few at a time can break as the chains separate during crucial cellular processes. (In Chapter 15, we'll see how H-bonded base pairs are essential for protein synthesis and DNA replication.)

### › Summary of Section 13.2

- › In soluble proteins, polar and ionic amino-acid side chains on the exterior interact with surrounding water, and nonpolar side chains in the interior interact with each other.
- › With polar-ionic heads *and* nonpolar tails, a soap dissolves grease *and* interacts with water.
- › Like soaps, phospholipids have dual polarity. They assemble into a water-impermeable lipid bilayer. In a cell membrane, the embedded portions of membrane proteins have exterior nonpolar side chains that interact with the nonpolar tails in the lipid bilayer through dispersion forces. Some antibiotics form channels with nonpolar exteriors and polar interiors that shuttle ions through the cell membrane.
- › DNA forms a double helix with a sugar-phosphate, polar-ionic exterior. In the interior, N-containing bases H bond in specific pairs and stack through dispersion forces.

## 13.3 WHY SUBSTANCES DISSOLVE: BREAKING DOWN THE SOLUTION PROCESS

The qualitative *macroscopic* rule “like dissolves like” is based on *molecular* interactions between the solute and the solvent. To see *why* like dissolves like, we'll break down the solution process conceptually into steps and examine each of them quantitatively.

### The Heat of Solution and Its Components

Before a solution forms, solute particles (ions or molecules) are attracting each other, as are solvent particles (molecules). For one to dissolve in the other, three steps must take place, each accompanied by an enthalpy change:

*Step 1. Solute particles separate from each other.* This step involves overcoming intermolecular (or ionic) attractions, so it is *endothermic*:

*Step 2. Solvent particles separate from each other.* This step also involves overcoming attractions, so it is *endothermic*, too:

*Step 3. Solute and solvent particles mix and form a solution.* The different particles attract each other and come together, so this step is *exothermic*:

The overall process is called a *thermochemical solution cycle*, and in yet another application of Hess's law, we combine the three individual enthalpy changes to find the **heat (or enthalpy) of solution** ( $\Delta H_{\text{soln}}$ ), the total enthalpy change that occurs when solute and solvent form a solution:

$$\Delta H_{\text{soln}} = \Delta H_{\text{solute}} + \Delta H_{\text{solvent}} + \Delta H_{\text{mix}} \quad (13.1)$$

Overall solution formation is exothermic or endothermic, and  $\Delta H_{\text{soln}}$  is either negative or positive, depending on the relative sizes of the individual  $\Delta H$  values:

- *Exothermic process:*  $\Delta H_{\text{soln}} < 0$ . If the sum of the endothermic terms ( $\Delta H_{\text{solute}} + \Delta H_{\text{solvent}}$ ) is *smaller* than the exothermic term ( $\Delta H_{\text{mix}}$ ), the process is exothermic and  $\Delta H_{\text{soln}}$  is negative (Figure 13.14A).
- *Endothermic process:*  $\Delta H_{\text{soln}} > 0$ . If the sum of the endothermic terms is *larger* than the exothermic term, the process is endothermic and  $\Delta H_{\text{soln}}$  is positive (Figure 13.14B). If  $\Delta H_{\text{soln}}$  is highly positive, the solute may not dissolve significantly in that solvent.

#### Student Hot Spot

Student data indicate that you may struggle with the concept of energy changes and the solution process. Access the Smartbook to view additional Learning Resources on this topic.

**Figure 13.14** Enthalpy components of the heat of solution. **A**,  $\Delta H_{\text{mix}}$  is larger than the sum of  $\Delta H_{\text{solute}}$  and  $\Delta H_{\text{solvent}}$ , so  $\Delta H_{\text{soln}}$  is negative. **B**,  $\Delta H_{\text{mix}}$  is smaller than the sum of  $\Delta H_{\text{solute}}$  and  $\Delta H_{\text{solvent}}$ , so  $\Delta H_{\text{soln}}$  is positive.

## The Heat of Hydration: Dissolving Ionic Solids in Water

The  $\Delta H_{\text{solvent}}$  and  $\Delta H_{\text{mix}}$  components of the solution cycle are difficult to measure individually. Combined, they equal the enthalpy change for **solvation**, the process of surrounding a solute particle with solvent particles:

$$\Delta H_{\text{solvation}} = \Delta H_{\text{solvent}} + \Delta H_{\text{mix}}$$

Solvation in water is called **hydration**. Thus, enthalpy changes for separating the water molecules ( $\Delta H_{\text{solvent}}$ ) and mixing the separated solute with them ( $\Delta H_{\text{mix}}$ ) are combined into the **heat** (or enthalpy) **of hydration** ( $\Delta H_{\text{hydr}}$ ). In water, Equation 13.1 becomes

$$\Delta H_{\text{soln}} = \Delta H_{\text{solute}} + \Delta H_{\text{hydr}}$$

The heat of hydration is a key factor in dissolving an ionic solid. Breaking the H bonds in water is more than compensated for by forming the stronger ion-dipole forces, so hydration of an ion is *always* exothermic. The  $\Delta H_{\text{hydr}}$  of an ion is defined as the enthalpy change for the hydration of 1 mol of separated (gaseous) ions:

**Importance of Charge Density** Heats of hydration exhibit trends based on the ion's **charge density**, the ratio of its charge to its volume. In general, the higher the charge density, the more negative  $\Delta H_{\text{hydr}}$  is. Coulomb's law says that the higher the charge of an ion and the smaller its radius, the closer it gets to the oppositely charged pole of an  $\text{H}_2\text{O}$  molecule (see Figure 2.12), and the stronger the attraction. Thus,

- A 2+ ion attracts  $\text{H}_2\text{O}$  molecules more strongly than a 1+ ion of similar size.
- A small 1+ ion attracts  $\text{H}_2\text{O}$  molecules more strongly than a large 1+ ion.

Periodic trends in  $\Delta H_{\text{hydr}}$  values are based on trends in charge density (Table 13.4):

- *Down a group*, the charge stays the same and the size increases; thus, the charge densities decrease, as do the  $\Delta H_{\text{hydr}}$  values.
- *Across a period*, say, from Group 1A(1) to Group 2A(2), the 2A ion has a smaller radius *and* a higher charge, so its charge density and  $\Delta H_{\text{hydr}}$  are greater.

**Components of Aqueous Heats of Solution** To separate an ionic solute,  $\text{MX}$ , into gaseous ions requires a lot of energy ( $\Delta H_{\text{solute}}$ ); recall from Chapter 9 that this is the lattice energy, and it is highly positive:

Thus, for ionic compounds in water, the heat of solution is the lattice energy (always positive) plus the combined heats of hydration of the ions (always negative):

$$\Delta H_{\text{soln}} = \Delta H_{\text{lattice}} + \Delta H_{\text{hydr}} \text{ of the ions} \quad (13.2)$$

Trends in Ionic Heats of Hydration		
Ion	Ionic Radius (pm)	$\Delta H_{\text{hydr}}$ (kJ/mol)
<b>Group 1A(1)</b>		
$\text{Na}^+$	102	−410
$\text{K}^+$	138	−336
$\text{Rb}^+$	152	−315
$\text{Cs}^+$	167	−282
<b>Group 2A(2)</b>		
$\text{Mg}^{2+}$	72	−1903
$\text{Ca}^{2+}$	100	−1591
$\text{Sr}^{2+}$	118	−1424
$\text{Ba}^{2+}$	135	−1317
<b>Group 7A(17)</b>		
$\text{F}^-$	133	−431
$\text{Cl}^-$	181	−313
$\text{Br}^-$	196	−284
$\text{I}^-$	220	−247

**Table 13.4**

Figure 13.15 Enthalpy diagrams for three ionic compounds dissolving in water.

Once again, the sizes of the individual terms determine the sign of  $\Delta H_{\text{soln}}$ .

Figure 13.15 shows qualitative enthalpy diagrams for three ionic solutes dissolving in water:

- *NaCl*. Sodium chloride has a small positive  $\Delta H_{\text{soln}}$  (3.9 kJ/mol) because its lattice energy is only slightly greater than the combined ionic heats of hydration: if you dissolve NaCl in water in a flask, you don't feel the small temperature change.
- *NaOH*. Sodium hydroxide has a large negative  $\Delta H_{\text{soln}}$  (−44.5 kJ/mol) because its lattice energy is much *smaller* than the combined ionic heats of hydration: if you dissolve NaOH in water, the flask feels hot.
- *$\text{NH}_4\text{NO}_3$* . Ammonium nitrate has a large positive  $\Delta H_{\text{soln}}$  (25.7 kJ/mol) because its lattice energy is much *larger* than the combined ionic heats of hydration: if you dissolve  $\text{NH}_4\text{NO}_3$  in water, the flask feels cold.

Hot and cold “packs” consist of a thick outer pouch of water and a thin inner pouch of a salt. A squeeze breaks the inner pouch, and the salt dissolves. Most hot packs use anhydrous  $\text{CaCl}_2$  ( $\Delta H_{\text{soln}} = -82.8$  kJ/mol). In Japan, some soup is sold in double-walled cans with a salt in a packet immersed in water between the walls. Open the can and the packet breaks, the salt dissolves, and the soup quickly warms to about 90°C. Cold packs use  $\text{NH}_4\text{NO}_3$  ( $\Delta H_{\text{soln}} = 25.7$  kJ/mol). A cold pack can keep the solution at 0°C for about half an hour, long enough to soothe a sprain.

### SAMPLE PROBLEM 13.2

### Calculating an Aqueous Ionic Heat of Solution

**Problem** With secondary applications ranging from sedative to fire retardant, calcium bromide is used primarily in concentrated solution as an industrial drilling fluid.

- (a) Use Table 13.4 and the lattice energy (2132 kJ/mol) to find the heat of solution (kJ/mol) of calcium bromide.  
 (b) Draw an enthalpy diagram for this solution process.

#### (a) Calculating the heat of solution of $\text{CaBr}_2$ .

**Plan** We are given, or can look up, the individual enthalpy components for a salt dissolving in water and have to determine their signs to calculate the overall heat of solution ( $\Delta H_{\text{soln}}$ ). The components are the lattice energy (the heat absorbed when the solid separates into gaseous ions) and the heat of hydration for each ion (the heat

released when the ion becomes hydrated). The lattice energy is always positive, so  $\Delta H_{\text{lattice}} = 2132 \text{ kJ/mol}$ . Heats of hydration are always negative, so from Table 13.4,  $\Delta H_{\text{hydr}}$  of  $\text{Ca}^{2+} = -1591 \text{ kJ/mol}$  and  $\Delta H_{\text{hydr}}$  of  $\text{Br}^- = -284 \text{ kJ/mol}$ . We use Equation 13.2, noting that there are 2 mol of  $\text{Br}^-$ , to obtain  $\Delta H_{\text{soln}}$ .

#### Solution

$$\begin{aligned}\Delta H_{\text{soln}} &= \Delta H_{\text{lattice}} + \Delta H_{\text{hydr of the ions}} \\ &= \Delta H_{\text{lattice}} + \Delta H_{\text{hydr of Ca}^{2+}} + 2(\Delta H_{\text{hydr of Br}^-}) \\ &= 2132 \text{ kJ/mol} + (-1591 \text{ kJ/mol}) + 2(-284 \text{ kJ/mol}) \\ &= -27 \text{ kJ/mol}\end{aligned}$$

**Check** Rounding to check the math gives

$$2100 \text{ kJ/mol} - 1600 \text{ kJ/mol} - 560 \text{ kJ/mol} = -60 \text{ kJ/mol}$$

This small negative sum indicates that our answer is correct.

#### (b) Drawing an enthalpy diagram for the process of dissolving $\text{CaBr}_2$ .

**Plan** Along a vertical enthalpy axis, the lattice energy (endothermic) is represented by an upward arrow leading from solid salt to gaseous ions. The hydration of the ions (exothermic) is represented by a downward arrow from gaseous to hydrated ions. From part (a),  $\Delta H_{\text{soln}}$  is small and negative, so the downward arrowhead is slightly below the tail of the upward arrow.

**Solution** The enthalpy diagram is shown in the margin.

#### FOLLOW-UP PROBLEMS

**13.2A** Use the following data to find the combined heat of hydration for the ions in  $\text{KNO}_3$ :  $\Delta H_{\text{soln}} = 34.89 \text{ kJ/mol}$  and  $\Delta H_{\text{lattice}} = 685 \text{ kJ/mol}$ .

**13.2B** Use the following data to find the heat of hydration of  $\text{CN}^-$ :  $\Delta H_{\text{soln}}$  of  $\text{NaCN} = 1.21 \text{ kJ/mol}$ ,  $\Delta H_{\text{lattice}}$  of  $\text{NaCN} = 766 \text{ kJ/mol}$ , and  $\Delta H_{\text{hydr}}$  of  $\text{Na}^+ = -410. \text{ kJ/mol}$ .

**SOME SIMILAR PROBLEMS** 13.30, 13.31, 13.36, and 13.37

## The Solution Process and the Change in Entropy

The heat of solution ( $\Delta H_{\text{soln}}$ ) is one of two factors that determine whether a solute dissolves. The other factor is the natural tendency of a system of particles to spread out, which results in the system's kinetic energy becoming more dispersed or more widely distributed. A thermodynamic variable called **entropy** ( $S$ ) is directly related to the number of ways a system can distribute its energy, which involves the freedom of motion of the particles.

Let's see what it means for a system to "distribute its energy." We'll first compare the three physical states and then compare solute and solvent with solution.

**Entropy and the Three Physical States** The states of matter differ significantly in their entropy.

- In a solid, the particles are fixed in their positions with little freedom of motion. In a liquid, they can move around each other and so have greater freedom of motion. And in a gas, the particles have little restriction and much more freedom of motion.
- The more freedom of motion the particles have, the more ways they can distribute their kinetic energy; thus, a liquid has higher entropy than a solid, and a gas has higher entropy than a liquid:

$$S_{\text{gas}} > S_{\text{liquid}} > S_{\text{solid}}$$

- Thus, there is a *change* in entropy ( $\Delta S$ ) associated with a phase change, and it can be positive or negative. For example, when a liquid vaporizes, the change in entropy ( $\Delta S_{\text{vap}} = S_{\text{gas}} - S_{\text{liquid}}$ ) is positive ( $\Delta S_{\text{vap}} > 0$ , increase in entropy) since  $S_{\text{gas}} > S_{\text{liquid}}$ ; when a liquid freezes (fusion), the change in entropy ( $\Delta S_{\text{fus}} = S_{\text{solid}} - S_{\text{liquid}}$ ) is negative ( $\Delta S_{\text{fus}} < 0$ , decrease in entropy) since  $S_{\text{solid}} < S_{\text{liquid}}$ .

**Entropy and the Formation of Solutions** The formation of solutions also involves a change in entropy. A solution usually has higher entropy than the pure solute and pure solvent because the number of ways to distribute the energy is related to the number of interactions between different molecules. There are far more interactions possible when solute and solvent are mixed than when they are pure; thus,

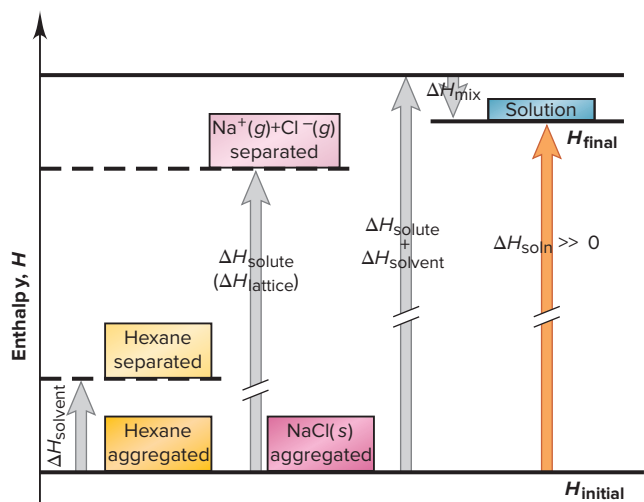

$$S_{\text{soln}} > (S_{\text{solute}} + S_{\text{solvent}}) \quad \text{or} \quad \Delta S_{\text{soln}} > 0$$

You know from everyday experience that solutions form naturally, but pure solutes and solvents don't: you've seen sugar dissolve in water, but you've never seen a sugar solution separate into pure sugar and water. In Chapter 20, we'll see that energy is needed to reverse the natural tendency of systems to distribute their energy—to get “mixed up.” Water treatment plants, oil refineries, steel mills, and many other industrial facilities expend a lot of energy to separate mixtures into pure components.

**Enthalpy vs. Entropy Changes in Solution Formation** Solution formation involves the interplay of two factors: systems change toward a state of *lower enthalpy* and *higher entropy*, so the relative sizes of  $\Delta H_{\text{soln}}$  and  $\Delta S_{\text{soln}}$  determine whether a solution forms. Let's consider three solute-solvent pairs to see which factor dominates in each case:

1. *NaCl in hexane.* Given their very different intermolecular forces, we predict that sodium chloride does *not* dissolve in hexane ( $\text{C}_6\text{H}_{14}$ ). An enthalpy diagram (Figure 13.16A) shows that separating the nonpolar solvent is easy because the dispersion forces are weak ( $\Delta H_{\text{solvent}} \geq 0$ ), but separating the solute requires supplying the very large  $\Delta H_{\text{lattice}}$  ( $\Delta H_{\text{solute}} \gg 0$ ). Mixing releases little heat because ion-induced dipole forces between  $\text{Na}^+$  (or  $\text{Cl}^-$ ) and hexane are weak ( $\Delta H_{\text{mix}} \leq 0$ ). Because the sum of the endothermic terms is *much* larger than the exothermic term,  $\Delta H_{\text{soln}} \gg 0$ . A solution does not form because the entropy increase from mixing solute and solvent would be much smaller than the enthalpy increase required to separate the solute:  $\Delta S_{\text{mix}} \ll \Delta H_{\text{solute}}$ .

2. *Octane in hexane.* We predict that octane ( $\text{C}_8\text{H}_{18}$ ) is soluble in hexane because both are held together by dispersion forces of similar strength; in fact, these two substances are miscible. That is, both  $\Delta H_{\text{solute}}$  and  $\Delta H_{\text{solvent}}$  are around zero. The similar forces mean that  $\Delta H_{\text{mix}}$  is also around zero. And a lot of heat is not released; in fact,  $\Delta H_{\text{soln}}$  is around zero (Figure 13.16B). So why does a solution form so readily? With no enthalpy change driving the process, octane dissolves in hexane because the entropy increases greatly when the pure substances mix:  $\Delta S_{\text{mix}} \gg \Delta H_{\text{soln}}$ .

**A NaCl.**  $\Delta H_{\text{mix}}$  is *much* smaller than  $\Delta H_{\text{solute}}$ ;  $\Delta H_{\text{soln}}$  is so much larger than the entropy increase due to mixing that NaCl does *not* dissolve.

**Figure 13.16** Enthalpy diagrams for dissolving (A) NaCl and (B) octane in hexane.

**B Octane.**  $\Delta H_{\text{soln}}$  is very small, but the entropy increase due to mixing is large, so octane *does* dissolve.

3.  $\text{NH}_4\text{NO}_3$  in water. A large enough increase in entropy can sometimes cause a solution to form even when the enthalpy increase is large ( $\Delta H_{\text{soln}} \gg 0$ ). As we saw previously, in Figure 13.15C, when ammonium nitrate dissolves in water, the process is highly endothermic; that is,  $\Delta H_{\text{lattice}} \gg \Delta H_{\text{hydr}}$  of the ions. Nevertheless, *the increase in entropy that occurs when the crystal breaks down and the ions mix with water molecules is greater than the increase in enthalpy*:  $\Delta S_{\text{soln}} > \Delta H_{\text{soln}}$ .

In Chapter 20, we'll return in depth to the relation between enthalpy and entropy to understand physical and chemical systems.

### › Summary of Section 13.3

- › In a thermochemical solution cycle, the heat of solution is the sum of the endothermic separations of solute and of solvent and the exothermic mixing of their particles.
- › In water, solvation (surrounding solute particles with solvent) is called hydration. For ions, heats of hydration depend on the ion's charge density but are always negative because ion-dipole forces are strong. Charge density exhibits periodic trends.
- › Systems naturally increase their entropy (distribute their energy in more ways). A gas has higher entropy than a liquid, which has higher entropy than a solid, and a solution has higher entropy than the pure solute and solvent.
- › Relative sizes of the enthalpy and entropy changes determine solution formation. A substance with a positive  $\Delta H_{\text{soln}}$  dissolves *only* if  $\Delta S_{\text{soln}}$  is larger than  $\Delta H_{\text{soln}}$ .

## 13.4 SOLUBILITY AS AN EQUILIBRIUM PROCESS

When an excess amount of solid is added to a solvent, particles leave the crystal, are surrounded by solvent, and move away. Some dissolved solute particles collide with undissolved solute and recrystallize, but, as long as the rate of dissolving is greater than the rate of recrystallizing, the concentration rises. At a given temperature, when solid is dissolving at the same rate as dissolved particles are recrystallizing, the concentration remains constant and *undissolved solute is in equilibrium with dissolved solute*:

Figure 13.17 shows an ionic solid in equilibrium with dissolved cations and anions. (We learned about the concept of equilibrium in Section 4.7 and saw how it occurs between phases in Section 12.2.)

Three terms express the extent of this solution process:

- A **saturated solution** is *at* equilibrium and contains the maximum amount of dissolved solute at a given temperature in the presence of undissolved solute. Therefore, if you filter off the solution and add more solute, the added solute doesn't dissolve.
- An **unsaturated solution** contains *less* than the equilibrium concentration of dissolved solute; add more solute, and more will dissolve until the solution is saturated.
- A **supersaturated solution** contains *more* than the equilibrium concentration and is unstable relative to the saturated solution. You can often prepare a supersaturated solution if the solute is more soluble at higher temperature. While heating, dissolve more than the amount required for saturation at some lower temperature, and then slowly cool the solution. If the excess solute remains dissolved, the solution is supersaturated. Add a "seed" crystal of solute or tap the container, and the excess solute crystallizes immediately, leaving behind a saturated solution (Figure 13.18).

### Effect of Temperature on Solubility

You know that more sugar dissolves in hot tea than in iced tea; in fact, temperature affects the solubility of most substances. Let's examine the effects of temperature on the solubility of solids and gases.

**Figure 13.17** Equilibrium in a saturated solution. At some temperature, the number of solute particles dissolving (*white arrows*) per unit time equals the number recrystallizing (*black arrows*).

**Figure 13.18** Sodium acetate crystallizing from a supersaturated solution. When a seed crystal of sodium acetate is added to a supersaturated solution of the compound (A), solute begins to crystallize (B) and continues until the remaining solution is saturated (C).

**Figure 13.19** Relation between solubility and temperature for several ionic compounds.

**Temperature and the Solubility of Solids in Water** Like sugar, *most solids are more soluble at higher temperatures* (Figure 13.19). Note that cerium sulfate is one of several exceptions, most of which are other sulfates. Some salts have higher solubility up to a certain temperature and then lower solubility at still higher temperatures.

The effect of temperature on solubility is a complex phenomenon, and the sign of  $\Delta H_{\text{soln}}$  does not reflect that complexity. Tabulated  $\Delta H_{\text{soln}}$  values give the enthalpy change for making a solution at the standard state of 1 *M*; but in order to understand the effect of temperature, we need to know the sign of the enthalpy change very close to the point of saturation, which may differ from the sign of the tabulated value. For example, tables give a negative  $\Delta H_{\text{soln}}$  for NaOH and a positive one for  $\text{NH}_4\text{NO}_3$ , yet both compounds are more soluble at higher temperatures. Thus, even though the effect of temperature indicates the equilibrium nature of solubility, no single measure can predict the effect for a given solute.

**Temperature and the Solubility of Gases in Water** The effect of temperature on *gas* solubility is much more predictable. When a solid dissolves in a liquid, the solute particles must separate, so  $\Delta H_{\text{solute}} > 0$ . In contrast, gas particles are already separated, so  $\Delta H_{\text{solute}} \approx 0$ . Because hydration is exothermic ( $\Delta H_{\text{hydr}} < 0$ ), the sum of these two terms is negative. Thus,  $\Delta H_{\text{soln}} < 0$  for all gases in water:

Thus, *gas solubility in water decreases with rising temperature (addition of heat)*. Gases have weak intermolecular forces with water. When the temperature rises, the average kinetic energy increases, allowing the gas particles to easily overcome these forces and re-enter the gas phase.

This behavior leads to *thermal pollution*. Many electric power plants use large amounts of water from a nearby river or lake for cooling, and the warmed water is returned to the source. The metabolic rates of fish and other aquatic animals increase in this warmer water, increasing their need for  $\text{O}_2$ . But the concentration of dissolved  $\text{O}_2$  is lower in warm water, so they become “oxygen deprived.” Also, the less dense warm water floats and prevents  $\text{O}_2$  from reaching the cooler water below. Thus, even creatures at deeper levels become oxygen deprived. Farther from the plant, the water temperature and  $\text{O}_2$  solubility return to normal. To mitigate the problem, cooling towers lower the temperature of the water before it exits the plant (Figure 13.20); nuclear power plants use a similar approach (Section 24.7).

**Figure 13.20** Preventing thermal pollution with cooling towers.

## Effect of Pressure on Solubility

Pressure has little effect on the solubility of liquids and solids because they are almost incompressible. But it has a *major* effect on the solubility of gases. Consider a piston-cylinder assembly with a gas above a saturated aqueous solution of the gas (Figure 13.21A). At equilibrium, at a given pressure, the same number of gas molecules enter and leave the solution per unit time:

Push down on the piston, and you disturb the equilibrium: gas volume decreases, so gas pressure (and concentration) increases, and gas particles collide with the liquid surface more often. Thus, more particles enter than leave the solution per unit time (Figure 13.21B). More gas dissolves to reduce this disturbance (a shift to the right in the preceding equation) until the system re-establishes equilibrium (Figure 13.21C).

The relation between gas pressure and solubility has many familiar applications. In a closed can of cola, dissolved  $\text{CO}_2$  is in equilibrium with 4 atm of  $\text{CO}_2$  in the small volume above the solution. Open the can and the dissolved  $\text{CO}_2$  bubbles out of solution until the drink goes “flat” because its  $\text{CO}_2$  concentration reaches equilibrium with  $\text{CO}_2$  in air ( $P_{\text{CO}_2} = 4 \times 10^{-4}$  atm). In a different situation (*see photo*), scuba divers who breathe compressed air have a high concentration of  $\text{N}_2$  dissolved in their blood. If they ascend too quickly, they may suffer decompression sickness (the “bends”), in which lower external pressure allows the dissolved  $\text{N}_2$  to form bubbles in the blood that block capillaries.

**Henry’s law** expresses the quantitative relationship between gas pressure and solubility: *the solubility of a gas ( $S_{\text{gas}}$ ) is directly proportional to the partial pressure of the gas ( $P_{\text{gas}}$ ) above the solution:*

$$S_{\text{gas}} = k_{\text{H}} \times P_{\text{gas}} \quad (13.3)$$

where  $k_{\text{H}}$  is the *Henry’s law constant* and is specific for a given gas-solvent combination at a given temperature. With  $S_{\text{gas}}$  in mol/L and  $P_{\text{gas}}$  in atm, the units of  $k_{\text{H}}$  are mol/L·atm, or mol·L<sup>-1</sup>·atm<sup>-1</sup>.

What happens to gases dissolved in the blood of a scuba diver?

**Figure 13.21** The effect of pressure on gas solubility.

## SAMPLE PROBLEM 13.3

## Using Henry's Law to Calculate Gas Solubility

**Problem** The partial pressure of carbon dioxide gas inside a bottle of cola is 4 atm at 25°C. What mass of CO<sub>2</sub> is dissolved in a 0.5-L bottle of cola? The Henry's law constant for CO<sub>2</sub> in water is 3.3×10<sup>-2</sup> mol/L·atm at 25°C.

**Plan** We know  $P_{\text{CO}_2}$  (4 atm) and the value of  $k_{\text{H}}$  (3.3×10<sup>-2</sup> mol/L·atm), so we substitute them into Equation 13.3 to find  $S_{\text{CO}_2}$  in mol/L. Then we multiply the solubility by the volume of cola and molar mass of CO<sub>2</sub> to obtain the mass of dissolved CO<sub>2</sub>.

**Solution**  $S_{\text{CO}_2} = k_{\text{H}} \times P_{\text{CO}_2} = (3.3 \times 10^{-2} \text{ mol/L} \cdot \text{atm})(4 \text{ atm}) = 0.1 \text{ mol/L}$

$$\text{Mass (g) CO}_2 = \frac{0.1 \text{ mol}}{\text{L}} \times 0.5 \text{ L} \times \frac{44.01 \text{ g CO}_2}{1 \text{ mol CO}_2} = 2 \text{ g CO}_2$$

**Check** The units are correct. We rounded to one significant figure to match the number of significant figures in the given values for the pressure and the volume of cola.

## FOLLOW-UP PROBLEMS

**13.3A** If air contains 78% N<sub>2</sub> by volume, what is the solubility of N<sub>2</sub> in water at 25°C and 1 atm ( $k_{\text{H}}$  for N<sub>2</sub> in H<sub>2</sub>O at 25°C = 7×10<sup>-4</sup> mol/L·atm)?

**13.3B** Dinitrogen monoxide (N<sub>2</sub>O), commonly known as *laughing gas*, is mixed with oxygen for use as an analgesic during dental surgery. A mixture of N<sub>2</sub>O and O<sub>2</sub> is 40% N<sub>2</sub>O by volume and has a total pressure of 1.2 atm; the solubility of N<sub>2</sub>O in water at 25°C is 1.2×10<sup>-2</sup> mol/L. Calculate  $k_{\text{H}}$  for N<sub>2</sub>O in H<sub>2</sub>O at this temperature.

**SOME SIMILAR PROBLEMS** 13.46 and 13.47

## › Summary of Section 13.4

- › A solution that contains the maximum amount of dissolved solute in the presence of excess undissolved solute is saturated. A saturated solution is in equilibrium with excess solute, because solute particles are entering and leaving the solution at the same rate. An unsaturated solution contains less than this amount.
- › Most solids are more soluble at higher temperatures.
- › All gases have a negative  $\Delta H_{\text{soln}}$  in water, so heating lowers gas solubility in water.
- › Henry's law says that the solubility of a gas is directly proportional to its partial pressure above the solution.

## 13.5 CONCENTRATION TERMS

Concentration is the *proportion* of a substance in a mixture, so it is an *intensive* property (like density and temperature), one that does not depend on the quantity of mixture: 1.0 L or 1.0 mL of 0.1 M NaCl have the same concentration. Concentration is a ratio of quantities (Table 13.5), most often solute to *solution*, but sometimes solute to *solvent*. Both parts of the ratio can be given in units of mass, volume, or amount (mol), and chemists express concentration by several terms, including molarity, molality, and various expressions of “parts of solute per part by solution.”

## Molarity and Molality

Two very common concentration terms are molarity and molality:

1. Molarity ( $M$ ) is the *number of moles of solute dissolved in 1 L of solution*:

$$\text{Molarity (} M \text{)} = \frac{\text{amount (mol) of solute}}{\text{volume (L) of solution}} \quad (13.4)$$

In Chapter 4, we used molarity to convert liters of solution into amount of dissolved solute. Molarity has two drawbacks that affect its use in precise work:

- *Effect of temperature.* A liquid expands when heated, so a unit volume of hot solution contains less solute than one of cold solution; thus, the molarity of the hot and cold solutions is different.

Table 13.5

## Concentration Definitions

Concentration Term	Ratio
Molarity ( $M$ )	$\frac{\text{amount (mol) of solute}}{\text{volume (L) of solution}}$
Molality ( $m$ )	$\frac{\text{amount (mol) of solute}}{\text{mass (kg) of solvent}}$
Parts by mass	$\frac{\text{mass of solute}}{\text{mass of solution}}$
Parts by volume	$\frac{\text{volume of solute}}{\text{volume of solution}}$
Mole fraction ( $X$ )	$\frac{\text{amount (mol) of solute}}{\text{amount (mol) of solute} + \text{amount (mol) of solvent}}$

- *Effect of mixing.* Because of solute-solvent interactions that are difficult to predict, *volumes may not be additive*: adding 500. mL of one solution to 500. mL of another may not give 1000. mL of final solution.

2. **Molality ( $m$ )** does not contain volume in its ratio; it is *the number of moles of solute dissolved in 1000 g (1 kg) of solvent*:

$$\text{Molality } (m) = \frac{\text{amount (mol) of solute}}{\text{mass (kg) of solvent}} \quad (13.5)$$

Note that molality includes the quantity of *solvent*, not of solution. For precise work, molality has two advantages over molarity:

- *Effect of temperature.* Molal solutions are based on *masses* of components, not *volume*. Since mass does not change with temperature, neither does molality.
- *Effect of mixing.* Unlike volumes, masses *are* additive: adding 500. g of one solution to 500. g of another *does* give 1000. g of final solution.

For these reasons, molality is the preferred term when temperature, and hence density, may change, as in a study of physical properties. Note that, in the case of water, 1 L has a mass of 1 kg, so *molality and molarity are nearly the same for dilute aqueous solutions*.

## SAMPLE PROBLEM 13.4

## Calculating Molality

**Problem** What is the molality of a solution prepared by dissolving 32.0 g of  $\text{CaCl}_2$  in 271 g of water?

**Plan** To use Equation 13.5, we convert the mass of  $\text{CaCl}_2$  (32.0 g) to amount (mol) using the molar mass (g/mol) and then divide by the mass of water (271 g), being sure to convert from grams to kilograms (see the road map).

**Solution** Converting from grams of solute to moles:

$$\text{Amount (mol) of CaCl}_2 = 32.0 \text{ g CaCl}_2 \times \frac{1 \text{ mol CaCl}_2}{110.98 \text{ g CaCl}_2} = 0.288 \text{ mol CaCl}_2$$

Finding the molality:

$$\begin{aligned} \text{Molality} &= \frac{\text{mol solute}}{\text{kg solvent}} = \frac{0.288 \text{ mol CaCl}_2}{271 \text{ g} \times \frac{1 \text{ kg}}{10^3 \text{ g}}} \\ &= 1.06 \text{ m CaCl}_2 \end{aligned}$$

**Check** The answer seems reasonable: the given amount (mol) of  $\text{CaCl}_2$  and mass (kg) of  $\text{H}_2\text{O}$  are about the same, so their ratio is about 1.

## Road Map

## FOLLOW-UP PROBLEMS

**13.4A** How many grams of glucose ( $C_6H_{12}O_6$ ) must be dissolved in 563 g of ethanol ( $C_2H_5OH$ ) to prepare a  $2.40 \times 10^{-2} m$  solution?

**13.4B** What is the molality of a solution made by dissolving 15.20 g of  $I_2$  in 1.33 mol of diethyl ether,  $(CH_3CH_2)_2O$ ?

**SOME SIMILAR PROBLEMS** 13.64 and 13.65

## Parts of Solute by Parts of Solution

Several concentration terms relate the parts of solute (or solvent) to the parts of *solution*. Both can be expressed in units of mass, volume, or amount (mol).

**Parts by Mass** The most common of these terms is **mass percent [% (w/w)]**, which you encountered in Chapter 3 as the fraction by mass of an element in a compound. The word *percent* means “per hundred,” so with respect to solution concentration, *mass percent* means mass of solute dissolved in 100. parts by mass of solution:

$$\begin{aligned} \text{Mass percent} &= \frac{\text{mass of solute}}{\text{mass of solute} + \text{mass of solvent}} \times 100 \\ &= \frac{\text{mass of solute}}{\text{mass of solution}} \times 100 \end{aligned} \quad (13.6)$$

Mass percent values appear commonly on jars of solid laboratory chemicals to indicate impurities.

Two very similar terms are parts per million (ppm) by mass and parts per billion (ppb) by mass, or grams of solute per million or per billion grams of solution: in Equation 13.6, you multiply by  $10^6$  or by  $10^9$ , respectively, instead of by 100, to obtain these much smaller concentrations. Environmental toxicologists use these units to measure pollutants. For example, TCDD (*tetrachlorodibenzodioxin*) (*see margin*), a byproduct of paper bleaching, is unsafe at soil levels above 1 ppb. From normal contact with air, water, and soil, North Americans have an average of 0.01 ppb TCDD in their tissues.

Is this deadly toxin in your body?

**Parts by Volume** The most common parts-by-volume term is **volume percent [% (v/v)]**, the volume of solute in 100. volumes of solution:

$$\text{Volume percent} = \frac{\text{volume of solute}}{\text{volume of solution}} \times 100 \quad (13.7)$$

For example, rubbing alcohol is an aqueous solution of isopropanol (a three-carbon alcohol) that contains 70 volumes of alcohol in 100. volumes of solution, or 70% (v/v).

Parts by volume is often used to express tiny concentrations of liquids or gases. Minor atmospheric components occur in parts per million by volume (ppmv). For example, about 0.05 ppmv of the toxic gas carbon monoxide (CO) is in clean air, 1000 times as much (50 ppmv of CO) in air over urban traffic, and 10,000 times as much (500 ppmv of CO) in cigarette smoke. *Pheromones* are compounds secreted by members of a species to signal food, danger, sexual readiness, and so forth. Many organisms, including dogs and monkeys, release pheromones, and researchers suspect that humans do as well. Some insect pheromones, such as the sexual attractant of the gypsy moth, are active at a few hundred molecules per milliliter of air, 100 parts per quadrillion by volume.

A concentration term often used in health-related facilities for aqueous solutions is % (w/v), a ratio of solute *weight* (actually mass) to solution *volume*. Thus, a 1.5% (w/v) NaCl solution contains 1.5 g of NaCl per 100. mL of *solution*.

**Parts by Mole: Mole Fraction** The **mole fraction (X)** of a solute is the ratio of the number of moles of solute to the total number of moles (solute plus solvent):

$$\text{Mole fraction (X)} = \frac{\text{amount (mol) of solute}}{\text{amount (mol) of solute} + \text{amount (mol) of solvent}} \quad (13.8)$$

Put another way, the mole fraction gives the proportion of solute (or solvent) particles in solution. The *mole percent* is the mole fraction expressed as a percentage:

$$\text{Mole percent (mol \%)} = \text{mole fraction} \times 100$$

**SAMPLE PROBLEM 13.5**
**Expressing Concentrations in Parts by Mass, Parts by Volume, and Mole Fraction**

**Problem (a)** Find the concentration of calcium ion (in ppm) in a 3.50-g pill that contains 40.5 mg of  $\text{Ca}^{2+}$ .

**(b)** The label on a 0.750-L bottle of Italian chianti says “11.5% alcohol by volume.” How many liters of alcohol does the wine contain?

**(c)** A sample of rubbing alcohol contains 142 g of isopropyl alcohol ( $\text{C}_3\text{H}_7\text{OH}$ ) and 58.0 g of water. What are the mole fractions of alcohol and water?

**Plan (a)** We know the mass of  $\text{Ca}^{2+}$  (40.5 mg) and the mass of the pill (3.50 g). We convert the mass of  $\text{Ca}^{2+}$  from mg to g, find the mass ratio of  $\text{Ca}^{2+}$  to pill, and multiply by  $10^6$  to obtain the concentration in ppm. **(b)** We know the volume % (11.5%, or 11.5 parts by volume of alcohol to 100. parts of chianti) and the total volume (0.750 L), so we use Equation 13.7 to find the number of liters of alcohol. **(c)** We know the mass and formula of each component, so we convert masses to amounts (mol) and apply Equation 13.8 to find the mole fractions.

**Solution (a)** Finding parts per million by mass of  $\text{Ca}^{2+}$ . Combining the steps, we have

$$\begin{aligned} \text{ppm Ca}^{2+} &= \frac{\text{mass of Ca}^{2+}}{\text{mass of pill}} \times 10^6 = \frac{40.5 \text{ mg Ca}^{2+} \times \frac{1 \text{ g}}{10^3 \text{ mg}}}{3.50 \text{ g}} \times 10^6 \\ &= 1.16 \times 10^4 \text{ ppm Ca}^{2+} \end{aligned}$$

**(b)** Finding volume (L) of alcohol:

$$\text{Volume percent} = \frac{\text{volume of solute}}{\text{volume of solution}} \times 100$$

$$\text{Volume of alcohol} = \text{volume of solution} \times \frac{\text{volume percent}}{100}$$

$$\begin{aligned} \text{Volume (L) of alcohol} &= 0.750 \text{ L chianti} \times \frac{11.5 \text{ L alcohol}}{100. \text{ L chianti}} \\ &= 0.0862 \text{ L} \end{aligned}$$

**(c)** Finding mole fractions. Converting from mass (g) to amount (mol):

$$\text{Amount (mol) of C}_3\text{H}_7\text{OH} = 142 \text{ g C}_3\text{H}_7\text{OH} \times \frac{1 \text{ mol C}_3\text{H}_7\text{OH}}{60.09 \text{ g C}_3\text{H}_7\text{OH}} = 2.36 \text{ mol C}_3\text{H}_7\text{OH}$$

$$\text{Amount (mol) of H}_2\text{O} = 58.0 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}} = 3.22 \text{ mol H}_2\text{O}$$

Calculating mole fractions:

$$\begin{aligned} X_{\text{C}_3\text{H}_7\text{OH}} &= \frac{\text{moles of C}_3\text{H}_7\text{OH}}{\text{total moles}} = \frac{2.36 \text{ mol}}{2.36 \text{ mol} + 3.22 \text{ mol}} \\ &= 0.423 \\ X_{\text{H}_2\text{O}} &= \frac{\text{moles of H}_2\text{O}}{\text{total moles}} = \frac{3.22 \text{ mol}}{2.36 \text{ mol} + 3.22 \text{ mol}} \\ &= 0.577 \end{aligned}$$

**Check (a)** The mass ratio is about  $0.04 \text{ g}/4 \text{ g} = 10^{-2}$ , and  $10^{-2} \times 10^6 = 10^4$  ppm, so it seems correct. **(b)** The volume % is a bit more than 10%, so the volume of alcohol should be a bit more than 75 mL (0.075 L). **(c)** Always check that the *mole fractions add up to 1*:  $0.423 + 0.577 = 1.000$ .

**FOLLOW-UP PROBLEMS**

**13.5A** An alcohol solution contains 35.0 g of 1-propanol ( $\text{C}_3\text{H}_7\text{OH}$ ) and 150. g of ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ). Calculate the mass percent and the mole fraction of each alcohol.

**13.5B** A sample of gasoline contains 1.87 g of ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ), 27.4 g of 2,2,4-trimethylpentane (iso-octane,  $\text{C}_8\text{H}_{18}$ ), and 4.10 g of heptane ( $\text{C}_7\text{H}_{16}$ ). Calculate the mass percent and the mole percent of each component.

**SOME SIMILAR PROBLEMS** 13.70 and 13.71

## Interconverting Concentration Terms

All the terms we just discussed represent different ways of expressing concentration, so they are interconvertible. Keep these points in mind:

- To convert a term based on amount to one based on mass, you need the molar mass. These conversions are similar to the mass-mole conversions you've done earlier.
- To convert a term based on mass to one based on volume, you need the solution *density*. Given the mass of solution, the density (mass/volume) gives the volume, or vice versa.
- Molality includes quantity of *solvent*; the other terms include quantity of *solution*.

### Student Hot Spot

Student data indicate that you may struggle with converting from one concentration term to another. Access the SmartBook to view additional Learning Resources on this topic.

#### SAMPLE PROBLEM 13.6

#### Interconverting Concentration Terms

**Problem** Hydrogen peroxide is a powerful oxidizing agent; it is used in concentrated solution in rocket fuel and in dilute solution in hair bleach. An aqueous solution of  $\text{H}_2\text{O}_2$  is 30.0% by mass and has a density of 1.11 g/mL. Calculate the (a) molality, (b) mole fraction of  $\text{H}_2\text{O}_2$ , and (c) molarity.

**Plan** We know the mass % (30.0) and the density (1.11 g/mL). (a) For molality, we need the amount (mol) of solute and the mass (kg) of *solvent*. If we assume 100.0 g of solution, the mass % equals the grams of  $\text{H}_2\text{O}_2$ , which we subtract from 100.0 g to obtain the grams of solvent. To find molality, we convert grams of  $\text{H}_2\text{O}_2$  to moles and divide by mass of solvent (converting g to kg). (b) To find the mole fraction, we use the moles of  $\text{H}_2\text{O}_2$  [from part (a)] and convert the grams of  $\text{H}_2\text{O}$  to moles. Then we divide the moles of  $\text{H}_2\text{O}_2$  by the total moles. (c) To find molarity, we assume 100.0 g of solution and use the solution density to find the volume. Then we divide the moles of  $\text{H}_2\text{O}_2$  [from part (a)] by *solution* volume (in L).

**Solution** (a) From mass % to molality:

Finding mass of solvent (assume a 100.0-g sample of solution; 30.0% of 100 g = 30.0 g of  $\text{H}_2\text{O}_2$ ):

$$\text{Mass (g) of H}_2\text{O} = 100.0 \text{ g solution} - 30.0 \text{ g H}_2\text{O}_2 = 70.0 \text{ g H}_2\text{O}$$

Converting from grams of  $\text{H}_2\text{O}_2$  to moles:

$$\text{Amount (mol) of H}_2\text{O}_2 = 30.0 \text{ g H}_2\text{O}_2 \times \frac{1 \text{ mol H}_2\text{O}_2}{34.02 \text{ g H}_2\text{O}_2} = 0.882 \text{ mol H}_2\text{O}_2$$

Calculating molality:

$$\text{Molality of H}_2\text{O}_2 = \frac{\text{mol H}_2\text{O}_2}{\text{kg H}_2\text{O}} = \frac{0.882 \text{ mol H}_2\text{O}_2}{70.0 \text{ g} \times \frac{1 \text{ kg}}{10^3 \text{ g}}} = 12.6 \text{ m H}_2\text{O}_2$$

(b) From mass % to mole fraction:

$$\text{Amount (mol) of H}_2\text{O}_2 = 0.882 \text{ mol H}_2\text{O}_2 \text{ [from part (a)]}$$

$$\text{Amount (mol) of H}_2\text{O} = 70.0 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}} = 3.88 \text{ mol H}_2\text{O}$$

$$X_{\text{H}_2\text{O}_2} = \frac{\text{mol H}_2\text{O}_2}{\text{mol H}_2\text{O}_2 + \text{mol H}_2\text{O}} = \frac{0.882 \text{ mol}}{0.882 \text{ mol} + 3.88 \text{ mol}} = 0.185$$

(c) From mass % and density to molarity:

Using density to convert from solution mass to volume:

$$\text{Volume (mL) of solution} = 100.0 \text{ g} \times \frac{1 \text{ mL}}{1.11 \text{ g}} = 90.1 \text{ mL}$$

Calculating molarity:

$$\text{Molarity} = \frac{\text{mol H}_2\text{O}_2}{\text{L soln}} = \frac{0.882 \text{ mol H}_2\text{O}_2}{90.1 \text{ mL} \times \frac{1 \text{ L soln}}{10^3 \text{ mL}}} = 9.79 \text{ M H}_2\text{O}_2$$

**Check** Rounding shows the sizes of the answers to be reasonable: (a) The ratio  $\sim 0.9 \text{ mol}/0.07 \text{ kg}$  is greater than 10. (b)  $\sim 0.9 \text{ mol H}_2\text{O}_2/(1 \text{ mol} + 4 \text{ mol}) \approx 0.2$ . (c) The ratio of moles to liters ( $0.9/0.09$ ) is around 10.

**FOLLOW-UP PROBLEMS**

**13.6A** Concentrated hydrochloric acid is 11.8 *M* HCl and has a density of 1.190 g/mL. Calculate the mass %, molality, and mole fraction of HCl.

**13.6B** Concentrated aqueous solutions of calcium bromide are used in drilling oil wells. If a solution of CaBr<sub>2</sub> is 5.44 *m* and has a density of 1.70 g/mL, find the mass %, molarity, and mole percent of CaBr<sub>2</sub>.

**SOME SIMILAR PROBLEMS** 13.72–13.75

### › Summary of Section 13.5

- › The concentration of a solution is independent of the quantity of solution and can be expressed as molarity (mol solute/L solution), molality (mol solute/kg solvent), parts by mass (mass solute/mass solution), parts by volume (volume solute/volume solution), or mole fraction [mol solute/(mol solute + mol solvent)] (Table 13.5).
- › Molality is based on mass, so it is independent of temperature; the mole fraction gives the proportion of dissolved particles.
- › If the quantities of solute and solution as well as the solution density are known, the various ways of expressing concentration are interconvertible.

## 13.6 COLLIGATIVE PROPERTIES OF SOLUTIONS

The presence of solute gives a solution different physical properties than the pure solvent has. But, in the case of four important properties, it is the *number* of solute particles, *not* their chemical identity, that makes the difference. These **colligative properties** (*colligative* means “collective”) are vapor pressure lowering, boiling point elevation, freezing point depression, and osmotic pressure. Most of these effects are small, but they have many applications, including some that are vital to organisms.

We predict the magnitude of a colligative property from the solute formula, which shows the number of particles in solution and is closely related to our classification of solutes (Chapter 4) by their ability to conduct an electric current (Figure 13.22):

1. **Electrolytes.** An aqueous solution of an **electrolyte** conducts a current because the solute separates into ions as it dissolves.
  - *Strong electrolytes*—soluble salts, strong acids, and strong bases—dissociate completely, so their solutions conduct well.
  - *Weak electrolytes*—weak acids and weak bases—dissociate very little, so their solutions conduct poorly.
2. **Nonelectrolytes.** Compounds such as sugar and alcohol do not dissociate into ions at all. They are **nonelectrolytes** because their solutions do not conduct a current.

Thus, we can predict that

- *For nonelectrolytes*, 1 mol of compound yields 1 mol of particles when it dissolves in solution. For example, 0.35 *M* glucose contains 0.35 mol of solute particles per liter.
- *For strong electrolytes*, 1 mol of compound dissolves to yield the amount (mol) of ions shown in the formula unit: 0.4 *M* Na<sub>2</sub>SO<sub>4</sub> has 0.8 mol of Na<sup>+</sup> ions and 0.4 mol of SO<sub>4</sub><sup>2-</sup> ions, or 1.2 mol of particles, per liter (see Sample Problem 4.2).
- *For weak electrolytes*, the calculation is complicated because the solution reaches equilibrium; we examine these systems in Chapters 18 and 19.

In this section, we discuss colligative properties of three types of solutions—those of nonvolatile nonelectrolytes, volatile nonelectrolytes, and strong electrolytes.

A Strong electrolyte

B Weak electrolyte

C Nonelectrolyte

**Figure 13.22** Conductivity of three types of electrolyte solutions. **A**, For strong electrolytes, the number of particles equals the number of ions in a formula unit. **B**, Weak electrolytes form few ions. **C**, For nonelectrolytes, the number of particles equals the number of molecules.

Source: A–C: © McGraw-Hill Education/Stephen Frisch, photographer

## Nonvolatile Nonelectrolyte Solutions

We start with solutions of *nonvolatile nonelectrolytes*, because they provide the clearest examples of the colligative properties. These solutions contain solutes that are not ionic and thus do not dissociate, and they have negligible vapor pressure at the boiling point of the solvent; sucrose (table sugar) dissolved in water is an example.

**Vapor Pressure Lowering** *The vapor pressure of a nonvolatile nonelectrolyte solution is always lower than the vapor pressure of the pure solvent.* The difference in vapor pressures is the **vapor pressure lowering ( $\Delta P$ )**.

1. *Why the vapor pressure of a solution is lower.* The fundamental reason for this lowering involves entropy, specifically the relative change in entropy that accompanies vaporization of solvent versus vaporization of the solution. A liquid vaporizes because a gas has higher entropy. In a closed container, vaporization continues until the numbers of particles leaving and entering the liquid phase per unit time are equal, that is, when the system reaches equilibrium. But, as we said, the entropy of a solution is already higher than that of a pure solvent, so fewer solvent particles need to vaporize to reach the same entropy. With fewer particles in the gas phase, the vapor above a solution has lower pressure (Figure 13.23).

**Figure 13.23** Effect of solute on the vapor pressure of solution.

2. *Quantifying vapor pressure lowering.* **Raoult's law** says that the vapor pressure of solvent above a solution ( $P_{\text{solvent}}$ ) equals the mole fraction of solvent ( $X_{\text{solvent}}$ ) times the vapor pressure of the pure solvent ( $P_{\text{solvent}}^{\circ}$ ):

$$P_{\text{solvent}} = X_{\text{solvent}} \times P_{\text{solvent}}^{\circ} \quad (13.9)$$

Since  $X_{\text{solvent}}$  is less than 1 in a solution,  $P_{\text{solvent}}$  is less than  $P_{\text{solvent}}^{\circ}$ . An **ideal solution** is one that follows Raoult's law at any concentration. However, just as real gases deviate from ideality, so do real solutions. In practice, Raoult's law works reasonably well for *dilute* solutions and becomes exact at infinite dilution.

Let's see how the *amount* of dissolved solute affects  $\Delta P$ . The solution consists of solvent and solute, so the sum of their mole fractions equals 1:

$$X_{\text{solvent}} + X_{\text{solute}} = 1; \quad \text{thus} \quad X_{\text{solvent}} = 1 - X_{\text{solute}}$$

From Raoult's law, we have

$$P_{\text{solvent}} = X_{\text{solvent}} \times P_{\text{solvent}}^{\circ} = (1 - X_{\text{solute}}) \times P_{\text{solvent}}^{\circ}$$

Multiplying through on the right side gives

$$P_{\text{solvent}} = P_{\text{solvent}}^{\circ} - (X_{\text{solute}} \times P_{\text{solvent}}^{\circ})$$

Rearranging and introducing  $\Delta P$  gives

$$P_{\text{solvent}}^{\circ} - P_{\text{solvent}} = \Delta P = X_{\text{solute}} \times P_{\text{solvent}}^{\circ} \quad (13.10)$$

Thus,  $\Delta P$  equals the mole fraction of solute times the vapor pressure of the pure solvent—a relationship applied in the next sample problem.

## SAMPLE PROBLEM 13.7

Using Raoult's Law to Find  $\Delta P$ 

**Problem** Find the vapor pressure lowering,  $\Delta P$ , when 10.0 mL of glycerol ( $\text{C}_3\text{H}_8\text{O}_3$ ) is added to 500. mL of water at 50.°C. At this temperature, the vapor pressure of pure water is 92.5 torr and its density is 0.988 g/mL. The density of glycerol is 1.26 g/mL.

**Plan** To calculate  $\Delta P$ , we use Equation 13.10. We are given the vapor pressure of pure water ( $P_{\text{H}_2\text{O}}^\circ = 92.5$  torr), so we just need the mole fraction of glycerol,  $X_{\text{glycerol}}$ . We convert the given volume of glycerol (10.0 mL) to mass using the given density (1.26 g/mL), find the molar mass from the formula, and convert mass (g) to amount (mol). The same procedure gives amount of  $\text{H}_2\text{O}$ . From these amounts, we find  $X_{\text{glycerol}}$  and  $\Delta P$ .

**Solution** Calculating the amount (mol) of glycerol and of water:

$$\begin{aligned}\text{Amount (mol) of glycerol} &= 10.0 \text{ mL glycerol} \times \frac{1.26 \text{ g glycerol}}{1 \text{ mL glycerol}} \times \frac{1 \text{ mol glycerol}}{92.09 \text{ g glycerol}} \\ &= 0.137 \text{ mol glycerol}\end{aligned}$$

$$\begin{aligned}\text{Amount (mol) of H}_2\text{O} &= 500. \text{ mL H}_2\text{O} \times \frac{0.988 \text{ g H}_2\text{O}}{1 \text{ mL H}_2\text{O}} \times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}} \\ &= 27.4 \text{ mol H}_2\text{O}\end{aligned}$$

Calculating the mole fraction of glycerol:

$$X_{\text{glycerol}} = \frac{0.137 \text{ mol}}{0.137 \text{ mol} + 27.4 \text{ mol}} = 0.00498$$

Finding the vapor pressure lowering:

$$\Delta P = X_{\text{glycerol}} P_{\text{H}_2\text{O}}^\circ = 0.00498 \times 92.5 \text{ torr} = 0.461 \text{ torr}$$

**Check** The amount of each component seems correct: for glycerol,  $\sim 10 \text{ mL} \times 1.25 \text{ g/mL} \div 100 \text{ g/mol} = 0.125 \text{ mol}$ ; for  $\text{H}_2\text{O}$ ,  $\sim 500 \text{ mL} \times 1 \text{ g/mL} \div 20 \text{ g/mol} = 25 \text{ mol}$ . The small  $\Delta P$  is reasonable because the mole fraction of solute is small.

**Comment 1.** We can also find  $X_{\text{H}_2\text{O}}$  ( $1 - 0.00498 = 0.99502$ ) and use Equation 13.9 to calculate  $P_{\text{H}_2\text{O}}$  (92.0 torr). Then  $P_{\text{H}_2\text{O}}^\circ - P_{\text{H}_2\text{O}}$  gives  $\Delta P$  (with fewer significant figures).

**2.** The calculation assumes that glycerol is nonvolatile. At 1 atm, glycerol boils at 290.0°C, so the vapor pressure of glycerol at 50°C is negligible.

**3.** We have assumed the solution is close to ideal and that Raoult's law holds.

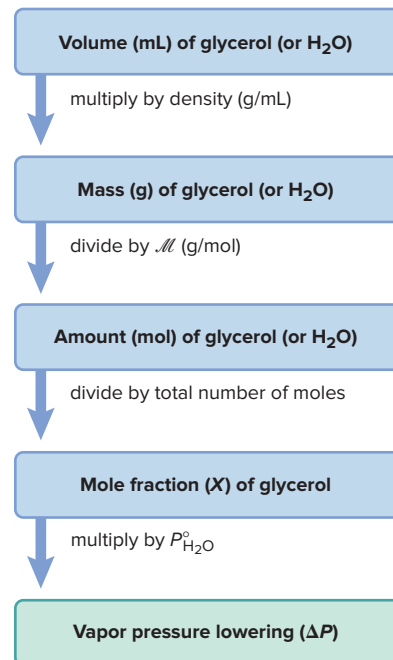

## FOLLOW-UP PROBLEMS

**13.7A** Calculate the vapor pressure lowering of a solution of 2.00 g of aspirin ( $\mathcal{M} = 180.15 \text{ g/mol}$ ) in 50.0 g of methanol ( $\text{CH}_3\text{OH}$ ) at 21.2°C. Methanol has a vapor pressure of 101 torr at this temperature.

**13.7B** Because menthol ( $\text{C}_{10}\text{H}_{20}\text{O}$ ) has a minty taste and soothes throat soreness, it is added to many medicinal products. Find the vapor pressure (in torr) of a solution that contains 6.49 g of menthol in 25.0 g of ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) at 22°C. Ethanol has a vapor pressure of 6.87 kPa at this temperature (101.325 kPa = 1 atm).

**SOME SIMILAR PROBLEMS** 13.96 and 13.97

## Road Map

**Boiling Point Elevation** A solution boils at a higher temperature than the pure solvent. This colligative property results from the vapor pressure lowering:

1. *Why a solution boils at a higher  $T$ .* Recall that the boiling point,  $T_b$ , of a liquid is the temperature at which its vapor pressure equals the external pressure,  $P_{\text{ext}}$ . But, the vapor pressure of a solution is always lower than that of the pure solvent. Therefore, it is lower than  $P_{\text{ext}}$  at  $T_b$  of the solvent, so the solution doesn't boil. Thus, **boiling point elevation** ( $\Delta T_b$ ) results because a higher temperature is needed to raise the solution's vapor pressure to equal  $P_{\text{ext}}$ .

We superimpose a phase diagram for the solution on one for the solvent to see  $\Delta T_b$  (Figure 13.24, next page): the gas-liquid line for the solution lies below the line for the solvent at any  $T$  and to the right of it at any  $P$ , and the line crosses 1 atm ( $P_{\text{ext}}$ , or  $P_{\text{atm}}$ ) at a higher  $T$ .

**Figure 13.24** Boiling and freezing points of solvent and solution. Phase diagrams of an aqueous solution (dashed lines) and of pure water (solid lines). (The slope of the solid-liquid line and the size of  $\Delta P$  are exaggerated.)

2. *Quantifying boiling point elevation.* Like vapor pressure lowering, boiling point elevation is proportional to the concentration of solute:

$$\Delta T_b \propto m \quad \text{or} \quad \Delta T_b = K_b m \quad (13.11)$$

where  $m$  is the solution molality and  $K_b$  is the *molal boiling point elevation constant*. Since  $\Delta T_b > 0$ , we subtract the lower solvent  $T_b$  from the higher solution  $T_b$ :

$$\Delta T_b = T_{b(\text{solution})} - T_{b(\text{solvent})}$$

Molality is used to determine the boiling point elevation because it relates to mole fraction and, thus, to particles of solute, and it is not affected by temperature.

The constant  $K_b$  has units of degrees Celsius per molal unit ( $^{\circ}\text{C}/m$ ) and is specific for a given solvent (Table 13.6). The  $K_b$  for water is  $0.512^{\circ}\text{C}/m$ , so  $\Delta T_b$  for aqueous solutions is quite small. For example, if you dissolve 1.00 mol of glucose (180. g; 1.00 mol of particles) or 0.500 mol of NaCl (29.2 g; also 1.00 mol of particles) in 1.00 kg of water at 1 atm, both solutions will boil at  $100.512^{\circ}\text{C}$  instead of  $100.000^{\circ}\text{C}$ .

Table 13.6

**Molal Boiling Point Elevation and Freezing Point Depression Constants of Several Solvents**

Solvent	Boiling Point ( $^{\circ}\text{C}$ )*	$K_b$ ( $^{\circ}\text{C}/m$ )	Freezing Point ( $^{\circ}\text{C}$ )	$K_f$ ( $^{\circ}\text{C}/m$ )
Acetic acid	117.9	3.07	16.6	3.90
Benzene	80.1	2.53	5.56	4.90
Carbon disulfide	46.2	2.34	-111.5	3.83
Carbon tetrachloride	76.5	5.03	-23	30.
Chloroform	61.7	3.63	-63.5	4.70
Diethyl ether	34.5	2.02	-116.2	1.79
Ethanol	78.5	1.22	-117.3	1.99
Water	100.0	0.512	0.0	1.86

\*At 1 atm

**Freezing Point Depression** A solution freezes at a lower temperature than the pure solvent, and this colligative property also results from vapor pressure lowering:

1. *Why a solution freezes at a lower  $T$ .* Only solvent vaporizes from a solution, so solute molecules are left behind. Similarly, *only solvent freezes*, again leaving solute molecules behind. The freezing point of a solution is the temperature at which its vapor pressure equals that of the pure solvent, that is, when solid solvent and liquid

solution are in equilibrium. **Freezing point depression ( $\Delta T_f$ )** occurs because the vapor pressure of the solution is always lower than that of the solvent, so the solution freezes at a lower temperature; that is, only at a lower temperature will solvent particles leave and enter the solid at the same rate. In Figure 13.24, the solid-liquid line for the solution is to the left of the pure solvent line at 1 atm, or at any pressure.

2. *Quantifying freezing point depression.* Like  $\Delta T_b$ , the freezing point depression is proportional to the molal concentration of solute:

$$\Delta T_f \propto m \quad \text{or} \quad \Delta T_f = K_f m \quad (13.12)$$

where  $K_f$  is the *molal freezing point depression constant*, which also has units of  $^\circ\text{C}/m$  (see Table 13.6). Also, like  $\Delta T_b$ ,  $\Delta T_f > 0$ , but in this case, we subtract the lower solution  $T_f$  from the higher solvent  $T_f$ :

$$\Delta T_f = T_{f(\text{solvent})} - T_{f(\text{solution})}$$

Here, too, the effect in aqueous solution is small because  $K_f$  for water is just  $1.86^\circ\text{C}/m$ . Thus, at 1 atm, 1 *m* glucose, 0.5 *m* NaCl, and 0.33 *m*  $\text{K}_2\text{SO}_4$ , all solutions with 1 mol of particles per kilogram of water, freeze at  $-1.86^\circ\text{C}$  instead of at  $0.00^\circ\text{C}$ .

### Student Hot Spot

Student data indicate that you may struggle with colligative property calculations. Access the Smartbook to view additional Learning Resources on this topic.

### SAMPLE PROBLEM 13.8

### Determining Boiling and Freezing Points of a Solution

**Problem** You add 1.00 kg of ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ) antifreeze to 4450 g of water in your car's radiator. What are the boiling and freezing points of the solution?

**Plan** To find the boiling and freezing points, we need  $\Delta T_b$  and  $\Delta T_f$ . We first find the molality by converting mass of solute (1.00 kg) to amount (mol) and dividing by mass of solvent (4450 g, converted to kg). Then we calculate  $\Delta T_b$  and  $\Delta T_f$  from Equations 13.11 and 13.12 (using constants from Table 13.6). We add  $\Delta T_b$  to the solvent boiling point and subtract  $\Delta T_f$  from its freezing point. The road map shows the steps.

**Solution** Calculating the molality:

$$\begin{aligned} \text{Amount (mol) of } \text{C}_2\text{H}_6\text{O}_2 &= 1.00 \text{ kg } \text{C}_2\text{H}_6\text{O}_2 \times \frac{10^3 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol } \text{C}_2\text{H}_6\text{O}_2}{62.07 \text{ g } \text{C}_2\text{H}_6\text{O}_2} \\ &= 16.1 \text{ mol } \text{C}_2\text{H}_6\text{O}_2 \\ \text{Molality} &= \frac{\text{mol solute}}{\text{kg solvent}} = \frac{16.1 \text{ mol } \text{C}_2\text{H}_6\text{O}_2}{4450 \text{ g } \text{H}_2\text{O} \times \frac{1 \text{ kg}}{10^3 \text{ g}}} = 3.62 \text{ m } \text{C}_2\text{H}_6\text{O}_2 \end{aligned}$$

Finding the boiling point elevation and  $T_{b(\text{solution})}$ , with  $K_b = 0.512^\circ\text{C}/m$ :

$$\Delta T_b = \frac{0.512^\circ\text{C}}{m} \times 3.62 \text{ m} = 1.85^\circ\text{C}$$

$$T_{b(\text{solution})} = T_{b(\text{solvent})} + \Delta T_b = 100.00^\circ\text{C} + 1.85^\circ\text{C} = 101.85^\circ\text{C}$$

Finding the freezing point depression and  $T_{f(\text{solution})}$ , with  $K_f = 1.86^\circ\text{C}/m$ :

$$\Delta T_f = \frac{1.86^\circ\text{C}}{m} \times 3.62 \text{ m} = 6.73^\circ\text{C}$$

$$T_{f(\text{solution})} = T_{f(\text{solvent})} - \Delta T_f = 0.00^\circ\text{C} - 6.73^\circ\text{C} = -6.73^\circ\text{C}$$

**Check** The changes in boiling and freezing points should be in the same proportion as the constants used. That is,  $\Delta T_b/\Delta T_f$  should equal  $K_b/K_f$ :  $1.85/6.73 = 0.275 = 0.512/1.86$ .

**Comment** These answers are approximate because the concentration far exceeds that of a *dilute* solution, for which Raoult's law is most accurate.

### FOLLOW-UP PROBLEMS

**13.8A** Carbon disulfide ( $\text{CS}_2$ ) has the unusual ability to dissolve several nonmetals as well as rubbers and resins. What are the boiling and freezing points of a solution consisting of 8.44 g of phosphorus ( $\text{P}_4$ ) dissolved in 60.0 g of  $\text{CS}_2$  (see Table 13.6)?

**13.8B** What is the lowest molality of ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ) solution that will protect your car's coolant from freezing at  $0.00^\circ\text{F}$ ? To make a solution of this molality, what mass of ethylene glycol must be added to 4.00 kg of water? (Assume that the solution is ideal.)

**SOME SIMILAR PROBLEMS** 13.98–13.103

### Road Map

**Osmotic Pressure** Another colligative property is observed when solutions of higher and lower concentrations are separated by a **semipermeable membrane**, one that allows solvent, but *not* solute, to pass through. The phenomenon is called **osmosis**: a net flow of solvent into the more concentrated solution causes a pressure difference known as *osmotic pressure*. Many organisms regulate internal concentrations by osmosis.

1. *Why osmotic pressure arises.* Consider a simple apparatus in which a semipermeable membrane lies at the curve of a U tube and separates an aqueous sugar solution from pure water. Water molecules pass in *either* direction, but the larger sugar molecules do not. Because sugar molecules are on the solution side of the membrane, fewer water molecules touch that side, so fewer leave the solution than enter it in a given time (Figure 13.25A). As a result, the solution maintains higher entropy. This *net flow of water into the solution* increases its volume and thus decreases its concentration.

As the height of the solution column rises and the height of the water column falls, the difference in the weights of the columns produces a pressure difference that resists more water entering and pushes some water back through the membrane. When water is being pushed out of the solution at the same rate it is entering, the system is at equilibrium (Figure 13.25B). The pressure difference at this point is the **osmotic pressure ( $\Pi$ )**, which is the same as the pressure that must be applied to *prevent* net movement of water from solvent to solution (or from lower to higher concentration, Figure 13.25C).

2. *Quantifying osmotic pressure.* The osmotic pressure is proportional to the number of solute particles in a given solution *volume*, that is, to the molarity ( $M$ ):

$$\Pi \propto \frac{n_{\text{solute}}}{V_{\text{soln}}} \quad \text{or} \quad \Pi \propto M$$

The proportionality constant is  $R$  times the absolute temperature  $T$ . Thus,

$$\Pi = \frac{n_{\text{solute}}}{V_{\text{soln}}} RT = MRT \quad (13.13)$$

The similarity of Equation 13.13 to the ideal gas law ( $P = nRT/V$ ) is not surprising, because both relate the pressure of a system to its concentration and temperature.

**The Underlying Theme of Colligative Properties** A common theme runs through the explanations of the four colligative properties of nonvolatile solutes. Each property arises because solute particles cannot move between two phases:

- They cannot enter the gas phase, which leads to *vapor pressure lowering* and *boiling point elevation*.

**Figure 13.25** The development of osmotic pressure. **A**, In a given time, more solvent enters the solution through the membrane than leaves. **B**, At equilibrium, solvent flow is equalized. **C**, The *osmotic pressure ( $\Pi$ )* prevents the volume change.

- They cannot enter the solid phase, which leads to *freezing point depression*.
- They cannot cross a semipermeable membrane, which leads to *osmotic pressure*.

In each situation, the presence of solute decreases the mole fraction of solvent, which lowers the number of solvent particles leaving the solution per unit time. This lowering maintains higher entropy and requires a new balance in numbers of particles moving between two phases per unit time, and this new balance results in the measured colligative property.

## Using Colligative Properties to Find Solute Molar Mass

Each colligative property is proportional to solute concentration. Thus, by measuring the property—lower freezing point, higher boiling point, and so forth—we determine the amount (mol) of solute particles and, given the mass of solute, the molar mass.

In principle, any of the colligative properties can be used, but generally only freezing point depression and osmotic pressure are widely used. Osmotic pressure creates the largest changes and, thus, the most precise measurements. Polymer chemists and biochemists estimate molar masses as great as  $10^5$  g/mol by measuring osmotic pressure. Because only a tiny fraction of a mole of a macromolecular solute dissolves, the change in the other colligative properties would be too small.

### SAMPLE PROBLEM 13.9

#### Determining Molar Mass from Colligative Properties

**Problem** Biochemists have discovered more than 400 mutant varieties of hemoglobin, the blood protein that binds  $O_2$  and carries it to the body's cells. A physician dissolves 21.5 mg of one variety in water to make 1.50 mL of solution at  $5.0^\circ\text{C}$ . She measures an osmotic pressure of 3.61 torr. What is the molar mass of the protein?

**Plan** We know the osmotic pressure ( $\Pi = 3.61$  torr),  $R$ , and  $T$  ( $5.0^\circ\text{C}$ ). We convert  $\Pi$  from torr to atm, and  $T$  from  $^\circ\text{C}$  to K, and then use Equation 13.13 to solve for molarity ( $M$ ). Then we calculate the amount (mol) of hemoglobin from the known volume (1.50 mL) and use the known mass (21.5 mg) to find  $\mathcal{M}$  (see the road map).

**Solution** Combining unit conversion steps and solving for molarity:

$$M = \frac{\Pi}{RT} = \frac{\frac{3.61 \text{ torr}}{760 \text{ torr/1 atm}}}{\left(0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}}\right)(273.15 \text{ K} + 5.0)} = 2.08 \times 10^{-4} M$$

Finding amount (mol) of solute (after changing mL to L):

$$\text{Amount (mol) of solute} = M \times V = \frac{2.08 \times 10^{-4} \text{ mol}}{1 \text{ L soln}} \times 0.00150 \text{ L soln} = 3.12 \times 10^{-7} \text{ mol}$$

Calculating molar mass of hemoglobin (after changing mg to g):

$$\mathcal{M} = \frac{0.0215 \text{ g}}{3.12 \times 10^{-7} \text{ mol}} = 6.89 \times 10^4 \text{ g/mol}$$

**Check** The small osmotic pressure implies a very low molarity. Hemoglobin is a biopolymer, so we expect a small number of moles [ $(\sim 2 \times 10^{-4} \text{ mol/L})(1.5 \times 10^{-3} \text{ L}) = 3 \times 10^{-7} \text{ mol}$ ] and a high  $\mathcal{M}$  [ $(\sim 21 \times 10^{-3} \text{ g}) / (3 \times 10^{-7} \text{ mol}) = 7 \times 10^4 \text{ g/mol}$ ]. Mammalian hemoglobin has a molar mass of 64,500 g/mol.

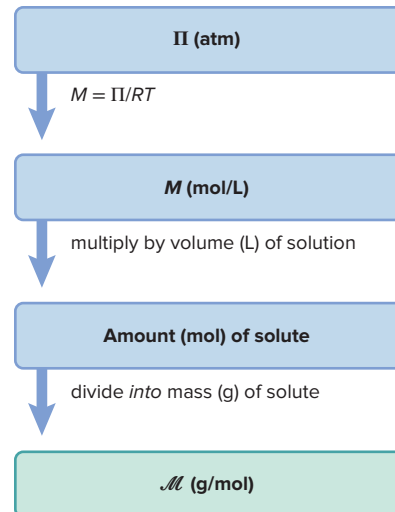

#### FOLLOW-UP PROBLEMS

**13.9A** Pepsin is an enzyme in the intestines of mammals that breaks down proteins into amino acids. A 12.0-mL aqueous solution contains 0.200 g of pepsin and has an osmotic pressure of 8.98 torr at  $27.0^\circ\text{C}$ . What is the molar mass of pepsin?

**13.9B** Naphthalene is the main ingredient in some mothballs. The freezing point of a solution made by dissolving 7.01 g of naphthalene in 200. g of benzene is  $4.20^\circ\text{C}$ . What is the molar mass of naphthalene?

**SOME SIMILAR PROBLEMS** 13.106 and 13.107

#### Road Map

## Volatile Nonelectrolyte Solutions

What is the effect on vapor pressure when the solute *is* volatile, that is, when the vapor consists of solute *and* solvent molecules? From Raoult's law (Equation 13.9),

$$P_{\text{solvent}} = X_{\text{solvent}} \times P_{\text{solvent}}^{\circ} \quad \text{and} \quad P_{\text{solute}} = X_{\text{solute}} \times P_{\text{solute}}^{\circ}$$

where  $X_{\text{solvent}}$  and  $X_{\text{solute}}$  are the mole fractions in the *liquid* phase. According to Dalton's law (Section 5.4), the total vapor pressure is the sum of the partial vapor pressures:

$$P_{\text{total}} = P_{\text{solvent}} + P_{\text{solute}} = (X_{\text{solvent}} \times P_{\text{solvent}}^{\circ}) + (X_{\text{solute}} \times P_{\text{solute}}^{\circ})$$

Thus, just as a nonvolatile solute lowers the vapor pressure of the solvent by making the solvent's mole fraction less than 1, *the presence of each volatile component lowers the vapor pressure of the other* by making each mole fraction less than 1.

Let's examine this idea with a solution of benzene ( $\text{C}_6\text{H}_6$ ) and toluene ( $\text{C}_7\text{H}_8$ ), which are miscible. The mole fractions of the two solution components in this example are equal:  $X_{\text{ben}} = X_{\text{tol}} = 0.500$ . At  $25^{\circ}\text{C}$ , the vapor pressures of the pure substances are 95.1 torr for benzene ( $P_{\text{ben}}^{\circ}$ ) and 28.4 torr for toluene ( $P_{\text{tol}}^{\circ}$ ). Note that benzene is *more volatile* than toluene. We find the partial pressures from Raoult's law:

$$P_{\text{ben}} = X_{\text{ben}} \times P_{\text{ben}}^{\circ} = 0.500 \times 95.1 \text{ torr} = 47.6 \text{ torr}$$

$$P_{\text{tol}} = X_{\text{tol}} \times P_{\text{tol}}^{\circ} = 0.500 \times 28.4 \text{ torr} = 14.2 \text{ torr}$$

Thus, the presence of benzene in the liquid lowers the vapor pressure of toluene, and vice versa.

Now let's calculate the mole fraction of each substance *in the vapor* by applying Dalton's law. Recall from Section 5.4 that  $X_{\text{A}} = P_{\text{A}}/P_{\text{total}}$ . Therefore, for benzene and toluene in the vapor,

$$X_{\text{ben}} = \frac{P_{\text{ben}}}{P_{\text{total}}} = \frac{47.6 \text{ torr}}{47.6 \text{ torr} + 14.2 \text{ torr}} = 0.770$$

$$X_{\text{tol}} = \frac{P_{\text{tol}}}{P_{\text{total}}} = \frac{14.2 \text{ torr}}{47.6 \text{ torr} + 14.2 \text{ torr}} = 0.230$$

The key point is that *the vapor has a higher mole fraction of the more volatile component*. Through a single vaporization-condensation step, a 50/50 *liquid* ratio of benzene to toluene created a 77/23 *vapor* ratio. Condense this vapor into a separate container, and the new *liquid* would have this 77/23 composition, and the new *vapor* above it would be enriched still further in the more volatile benzene.

In the laboratory method of **fractional distillation**, a solution of two or more volatile components is attached to a *fractionating column* packed with glass beads (or ceramic chunks), which increase surface area; the column is connected to a condenser and collection flask. As the solution is heated and the vapor mixture meets the beads, numerous vaporization-condensation steps enrich the mixture until the vapor leaving the column, and thus the liquid finally collected, consists only of the most volatile component. (As we'll see shortly, this method is essential in the oil refining industry.)

## Strong Electrolyte Solutions

For strong electrolyte solutions, the solute formula tells us the number of particles for determining colligative properties. For instance, the boiling point elevation ( $\Delta T_{\text{b}}$ ) of 0.050 *m* NaCl should be  $2 \times \Delta T_{\text{b}}$  of 0.050 *m* glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ), because NaCl dissociates into two particles per formula unit. Thus, we use a multiplying factor called the *van't Hoff factor* ( $i$ ), named after the Dutch chemist Jacobus van't Hoff (1852–1911):

$$i = \frac{\text{measured value for electrolyte solution}}{\text{expected value for nonelectrolyte solution}}$$

To calculate colligative properties for strong electrolyte solutions, we include  $i$ :

$$\text{For vapor pressure lowering:} \quad \Delta P = i(X_{\text{solute}} \times P_{\text{solvent}}^{\circ})$$

$$\text{For boiling point elevation:} \quad \Delta T_{\text{b}} = i(K_{\text{b}}m)$$

$$\text{For freezing point depression:} \quad \Delta T_{\text{f}} = i(K_{\text{f}}m)$$

$$\text{For osmotic pressure:} \quad \Pi = i(MRT)$$

**Nonideal Solutions and Ionic Atmospheres** If strong electrolyte solutions behaved ideally, the factor  $i$  would be the amount (mol) of particles in solution divided by the amount (mol) of dissolved solute; that is,  $i$  would be 2 for KBr, 3 for  $\text{Mg}(\text{NO}_3)_2$ , and so forth. However, *most strong electrolyte solutions are not ideal*, and the measured value of  $i$  is typically *lower* than the value expected from the formula. For example, for the boiling point elevation of 0.050  $m$  NaCl, the expected value is 2.0, but, from experiment, we have

$$i = \frac{\Delta T_b \text{ of } 0.050 \text{ } m \text{ NaCl}}{\Delta T_b \text{ of } 0.050 \text{ } m \text{ glucose}} = \frac{0.049^\circ\text{C}}{0.026^\circ\text{C}} = 1.9$$

It seems as though the ions are not behaving independently, even though other evidence indicates that soluble salts dissociate completely. One clue to understanding the results is that multiply-charged ions cause a larger deviation (Figure 13.26).

To explain this nonideal behavior, we picture positive ions clustered, on average, near negative ions, and vice versa, to form an **ionic atmosphere** of net opposite charge (Figure 13.27). In effect, each type of ion acts “tied up,” so its actual concentration seems *lower*. The *effective* concentration is the *stoichiometric* concentration, which is based on the formula, multiplied by  $i$ . The greater the charge, the stronger the attractions, which explains the larger deviation for salts with multiply-charged ions.

**Comparing Real Solutions and Real Gases** At ordinary conditions and concentrations, particles are *much* closer together in liquids than in gases. And, as a result, nonideal behavior is much more common for solutions, and the observed deviations are much larger. Nevertheless, the two systems have similarities:

- Gases display nearly ideal behavior at low pressures because the distances between particles are large. Similarly, the van't Hoff factor ( $i$ ) approaches the ideal value as the solution becomes more dilute, that is, as the distance between ions increases.
- Attractions between particles cause deviations from the expected pressure in gases and from the expected size of a colligative property in ionic solutions.
- For both real gases and real solutions, we use empirically determined numbers (van der Waals constants or van't Hoff factors) to transform theories (the ideal gas law or Raoult's law) into more useful relations.

**Figure 13.26** Nonideal behavior of strong electrolyte solutions. Van't Hoff factors ( $i$ ) for 0.050  $m$  solutions show the largest deviation for salts with multiply-charged ions. Glucose (a nonelectrolyte) behaves as expected.

**Figure 13.27** An ionic atmosphere model for nonideal behavior of electrolyte solutions.

### SAMPLE PROBLEM 13.10

### Depicting Strong Electrolyte Solutions

**Problem** A 0.952-g sample of magnesium chloride dissolves in 100. g of water in a flask.

- Which scene depicts the solution best?
- What is the amount (mol) represented by each green sphere?
- Assuming the solution is ideal, what is its freezing point (at 1 atm)?

**Plan** (a) We find the numbers of cations and anions per formula unit from the name and compare it with the three scenes. (b) We convert the given mass to amount (mol), use the answer from part (a) to find moles of chloride ions (*green spheres*), and divide by the number of green spheres to get moles/sphere. (c) We find the molality ( $m$ ) from amount (mol) of solute divided by the given mass of water (changed to kg). We multiply  $K_f$  for water (Table 13.6) by  $m$  to get  $\Delta T_f$ , and then subtract that from  $0.000^\circ\text{C}$  to get the solution freezing point.

**Solution** (a) The formula is  $\text{MgCl}_2$ ; only scene A has 1  $\text{Mg}^{2+}$  for every 2  $\text{Cl}^-$ .

$$(b) \text{ Amount (mol) of MgCl}_2 = \frac{0.952 \text{ g MgCl}_2}{95.21 \text{ g/mol MgCl}_2} = 0.0100 \text{ mol MgCl}_2$$

$$\text{Therefore, Amount (mol) of Cl}^- = 0.0100 \text{ mol MgCl}_2 \times \frac{2 \text{ Cl}^-}{1 \text{ MgCl}_2} = 0.0200 \text{ mol Cl}^-$$

$$\text{Moles/sphere} = \frac{0.0200 \text{ mol Cl}^-}{8 \text{ spheres}} = 2.50 \times 10^{-3} \text{ mol/sphere}$$

$$(c) \text{ Molality (} m \text{)} = \frac{\text{mol of solute}}{\text{kg of solvent}} = \frac{0.0100 \text{ mol MgCl}_2}{100. \text{ g} \times \frac{1 \text{ kg}}{10^3 \text{ g}}} = 0.100 \text{ } m \text{ MgCl}_2$$

Assuming an ideal solution,  $i = 3$  for  $\text{MgCl}_2$  (3 ions per formula unit), so we have

$$\Delta T_f = i(K_f m) = 3(1.86^\circ\text{C}/m \times 0.100 \text{ } m) = 0.558^\circ\text{C}$$

and

$$T_f = 0.000^\circ\text{C} - 0.558^\circ\text{C} = -0.558^\circ\text{C}$$

**Check** Let's quickly check the  $\Delta T_f$  in part (c): We have 0.01 mol dissolved in 0.1 kg, or 0.1  $m$ . Then, rounding  $K_f$ , we have about  $3(2^\circ\text{C}/m \times 0.1 \text{ } m) = 0.6^\circ\text{C}$ .

### FOLLOW-UP PROBLEMS

**13.10A** A solution is made by dissolving 31.2 g of potassium phosphate in 85.0 g of water in a beaker. (a) Which scene depicts the solution best? (b) Assuming ideal behavior, what is the boiling point of the solution (at 1 atm)?

**13.10B** The  $\text{MgCl}_2$  solution in the sample problem has a density of 1.006 g/mL at  $20.0^\circ\text{C}$ . (a) What is its osmotic pressure? (b) A U tube, with semipermeable membrane, is filled with this solution in the left arm and a glucose solution of equal molarity in the right. After time, which scene depicts the U tube best?

**SOME SIMILAR PROBLEMS** 13.108 and 13.109

## Applications of Colligative Properties

Two colligative properties, freezing point depression (or boiling point elevation) and osmotic pressure, have key applications that involve all three types of solutes we've discussed, nonvolatile and volatile nonelectrolytes and strong electrolytes.

**Uses of Freezing Point Depression** Applications of this property appear in everyday life, nature, and industry:

- *Plane de-icer and car antifreeze.* The main ingredient in plane de-icer and car antifreeze, ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ), lowers the freezing point of water in winter and raises its boiling point in summer. Due to extensive H bonding, ethylene glycol is miscible with water and nonvolatile at  $100^\circ\text{C}$ .

- **Biological antifreeze.** Structurally similar to ethylene glycol and also miscible with water, glycerol ( $C_3H_8O_3$ ) is produced by some fish and insects, including the common housefly, to lower the freezing point of their blood and thus allow them to survive winters.
- **De-icing sidewalks and roads.**  $NaCl$ , or a mixture of it with  $CaCl_2$ , is used to melt ice on roads. A small amount dissolves in the ice by lowering its freezing point and melting it. More salt dissolves, more ice melts, and so forth. An advantage of  $CaCl_2$  is that it has a highly negative  $\Delta H_{\text{soln}}$ , so heat is released when it dissolves, which melts more ice.
- **Refining petroleum and silicon.** In the oil refining industry, countless vaporization-condensation steps within a 30-m fractionating tower separate the hundreds of volatile compounds in crude oil into a few “fractions” based on boiling point range (Figure 13.28). Impure silicon is refined by continuous melting and refreezing into a sample pure enough for use in computer chips (Chapter 22).

**Uses of Osmotic Pressure** Of the four colligative properties, this one has the most applications vital to organisms.

- **Tonicity and cell shape.** The term *tonicity* refers to the tone, or firmness, of a cell. Placing a cell in an *isotonic* solution, one that has the same concentration of particles as the cell fluid, maintains the cell’s normal shape because water enters and leaves the cell at the same rate (Figure 13.29A). A *hypotonic* solution has a lower concentration of particles, so water enters the cell faster than it leaves, causing the cell to burst (Figure 13.29B). In contrast, a *hypertonic* solution has a higher concentration of particles, so the cell shrinks because water leaves faster than it enters (Figure 13.29C). To maintain cell shape, contact-lens rinse is isotonic saline ( $0.15\ M\ NaCl$ ), as are solutions used to deliver nutrients or drugs intravenously.
- **Absorption of water by trees.** Tree sap is a more concentrated solution than surrounding groundwater, so water passes through root membranes into the tree, creating an osmotic pressure that can exceed 20 atm in the tallest trees.
- **Regulation of water volume in the body.** Of the four major biological cations— $Na^+$ ,  $K^+$ ,  $Mg^{2+}$ , and  $Ca^{2+}$ —sodium ion has the primary role in regulating water volume. It accounts for over 90 mol % of cations *outside* a cell: high  $Na^+$  draws water out of the cell and low  $Na^+$  leaves more inside. And the primary role of the kidneys is to regulate  $Na^+$  concentration.
- **Food preservation.** Before refrigeration, salt was valued as a preservative. Packed onto food, salt causes microbes on the surface to shrivel as they lose water. In fact, it was so highly prized for this purpose that Roman soldiers were paid in salt, from which comes the word *salary*. Salt is also used to draw water out of cucumbers to make pickles.

**Figure 13.28** Fractional distillation in petroleum refining.

**Figure 13.29** Osmotic pressure and cell shape. Isotonic (A), hypotonic (B), and hypertonic (C) solutions influence the shape of a red blood cell.

### › Summary of Section 13.6

- › Colligative properties arise from the number, not the type, of dissolved solute particles.
- › Compared to pure solvent, a solution has higher entropy, which results in lower vapor pressure (Raoult's law), elevated boiling point, and depressed freezing point. A difference in concentration of a solute between two solutions gives rise to osmotic pressure.
- › Colligative properties are used to determine solute molar mass; osmotic pressure gives the most precise measurements.
- › When solute *and* solvent are volatile, each lowers the vapor pressure of the other, with the vapor pressure of the more volatile component greater. When the vapor is condensed, the new solution is richer in that component than the original solution.
- › Calculating colligative properties of strong electrolyte solutions requires a factor (*i*) that adjusts for the number of ions per formula unit. These solutions exhibit nonideal behavior because charge attractions effectively reduce the concentration of ions.

## 13.7 THE STRUCTURE AND PROPERTIES OF COLLOIDS

Particle size plays a defining role in three types of mixtures:

- *Suspensions*. Stir a handful of fine sand into a glass of water, and the particles are suspended at first but gradually settle to the bottom. Sand in water is a **suspension**, a *heterogeneous* mixture containing particles large enough (>1000 nm) to be visibly distinct from the surrounding fluid.
- *Solutions*. In contrast, stirring sugar into water forms a solution, a *homogeneous* mixture in which the particles are invisible, individual sugar molecules (around 1 nm) distributed evenly throughout the surrounding fluid.
- *Colloids*. Between these extremes is a large group of mixtures called *colloidal dispersions*, or **colloids**, in which a dispersed (solute-like) substance is distributed throughout a dispersing (solvent-like) substance. The particles are larger than simple molecules but too small to settle out.

In this section, we examine the classification and key features of colloids.

1. *Particle size and surface area*. Colloidal particles range in diameter from 1 to 1000 nm ( $10^{-9}$  to  $10^{-6}$  m). Each particle may be a single macromolecule (natural or synthetic) or an aggregate of many atoms, ions, or molecules. As a result of the small particle size, a colloid has a *very large total surface area*. A cube with 1-cm sides has a total surface area of 6 cm<sup>2</sup>. If we divide it equally into  $10^{12}$  cubes, each cube is the size of a large colloidal particle and the total surface area is 60,000 cm<sup>2</sup>, or 6 m<sup>2</sup>. The enormous surface area of a colloid attracts other particles through various intermolecular forces.

2. *Classification of colloids*. Colloids are commonly classified by the physical state of the dispersed and dispersing substances (Table 13.7). Many familiar commercial products and natural objects are colloids. Whipped cream and shaving cream are

**Table 13.7** Types of Colloids

Colloid Type	Dispersed Substance	Dispersing Substance	Example(s)
Aerosol	Liquid	Gas	Fog
Aerosol	Solid	Gas	Smoke
Foam	Gas	Liquid	Whipped cream
Solid foam	Gas	Solid	Marshmallow
Emulsion	Liquid	Liquid	Milk
Solid emulsion	Liquid	Solid	Butter
Sol	Solid	Liquid	Paint, cell fluid
Solid sol	Solid	Solid	Opal

**Figure 13.30** Light scattering and the Tyndall effect. **A**, The narrow, barely visible light beam that passes through a solution (*left*), is scattered and broadened by passing through a colloid (*right*). **B**, Sunlight is scattered by dust in air.

Source: (A) © McGraw-Hill Education/Charles Winters/Timeframe Photography, Inc. (B) © Corbis Royalty-Free RF

*foams*, a gas dispersed in a liquid. Styrofoam is a *solid foam*, a gas dispersed in a solid. Most biological fluids are aqueous *sols*, solids dispersed in water: proteins and nucleic acids are the colloidal-size particles dispersed in an aqueous fluid of ions and small molecules within a cell. Soaps and detergents work by forming an *emulsion*, a liquid dispersed in another liquid. Other emulsions are mayonnaise and hand cream. Bile salts convert fats to an emulsion in the watery fluid of the small intestine.

3. *Tyndall effect and Brownian motion*. Light passing through a colloid is scattered randomly because the dispersed particles have sizes similar to wavelengths of visible light (400 to 750 nm). The scattered light beam appears broader than one passing through a solution, an example of the **Tyndall effect** (Figure 13.30). Dust scatters sunlight shining through it, as does mist with headlight beams.

Under low magnification, colloidal particles exhibit *Brownian motion*, an erratic change of speed and direction. Brownian motion results from collisions of the particles with molecules of the dispersing medium, and Einstein's explanation of it in 1905 led many to accept the molecular nature of matter.

4. *Stabilizing and destabilizing colloids*. Why *don't* colloidal particles aggregate and settle out? Colloidal particles dispersed in water have charged surfaces that stabilize the colloid through ion-dipole forces. Molecules with dual polarities, like lipids and soaps, form spherical *micelles*, with the charged heads on the exterior and hydrocarbon tails in the interior (Section 13.2). Aqueous proteins mimic this arrangement, with charged amino acid groups facing the water and nonpolar groups buried within the molecule. Oily particles can be dispersed in water by adding ions, which are adsorbed onto their surfaces. Repulsions between the ions on the oil and partial charges on water molecules prevent the particles from aggregating.

Despite these forces, various methods that coagulate the particles destabilize the colloid. Heating makes the particles collide more often and with enough force to coalesce and settle out. Addition of an electrolyte solution containing oppositely charged ions neutralizes the surface charges, so the particles coagulate and settle. In smokestack gases from a coal-burning power plant, ions become adsorbed onto uncharged colloidal particles, which are then attracted to the charged plates of a device called a *Cottrell precipitator* installed in the stack. At the mouths of rivers, where salt concentrations increase near an ocean or sea, colloidal clay particles coalesce into muddy deltas, like those of the Mississippi and the Nile (Figure 13.31). Thus, the city of New Orleans and the ancient Egyptian empire were made possible by large-scale colloid chemistry.

The upcoming Chemical Connections essay applies solution and colloid chemistry to the purification of water for residential and industrial use.

## › Summary of Section 13.7

- › Particles in a colloid are smaller than those in a suspension and larger than those in a solution.
- › Colloids are classified by the physical states of the dispersed and dispersing substances and involve many combinations of gas, liquid, and/or solid.
- › Colloids have extremely large surface areas, scatter incoming light (Tyndall effect), and exhibit random (Brownian) motion.
- › Colloidal particles in water are stabilized by charged surfaces that keep them dispersed, but they can be coagulated by heating or by the addition of ions.
- › Solution behavior and colloid chemistry are applied to water treatment and purification.

Most water destined for human use comes from lakes, rivers, reservoirs, or groundwater. Present in this essential resource may be soluble toxic organic compounds and high concentrations of  $\text{NO}_3^-$  and  $\text{Fe}^{3+}$ , colloidal clay and microbes, and suspended debris. Let's see how water is treated to remove these dissolved, dispersed, and suspended particles.

## Water Treatment Plants

Treating water involves several steps (Figure B13.1):

**Step 1. Screening and settling.** As water enters the facility, screens remove debris, and settling removes sand and other particles.

**Step 2. Coagulating.** This step and the next two remove colloids. These particles have negative surfaces that repel each other. Added aluminum sulfate [cake alum;  $\text{Al}_2(\text{SO}_4)_3$ ] or iron(III) chloride ( $\text{FeCl}_3$ ), which supply  $\text{Al}^{3+}$  or  $\text{Fe}^{3+}$  ions that neutralize the charges, coagulates the particles through intermolecular forces.

**Step 3. Flocculating and sedimenting.** Mixing water and flocculating agents in large basins causes a fluffy *floc* to form. Added cationic polymers form long-chain bridges between floc particles, which grow bigger and flow into other basins, where they form a sediment and are removed. Some plants use *dissolved air flotation* (DAF) instead: bubbles forced through the water attach to the floc, and the floating mass is skimmed.

**Step 4. Filtering.** Various filters remove remaining particles. In *slow sand filters*, the water passes through sand and/or gravel of increasing particle size. In *rapid sand filters*, the sand is back-washed with water, and the colloidal mass is removed. Membrane filters (*not shown*) with pore sizes of 0.1–10  $\mu\text{m}$  are thin tubes bundled together inside a vessel. The water is forced into these tubes, and the colloid-free filtrate is collected from a large central tube. Filtration is very effective at removing microorganisms resistant to disinfectants.

**Step 5. Disinfecting.** Water sources often contain harmful microorganisms that are killed by one of three agents:

- Chlorine, as aqueous bleach ( $\text{ClO}^-$ ) or  $\text{Cl}_2$ , is most common, but carcinogenic chlorinated organic compounds can form.
- UV light emitted by high-intensity fluorescent tubes disinfects by disrupting microorganisms' DNA.
- Ozone ( $\text{O}_3$ ) gas is a powerful oxidizing agent.

Sodium fluoride (NaF) to prevent tooth decay and phosphate salts to prevent leaching of lead from pipes may then be added.

**Step 6 (not shown). Adsorbing onto granular activated carbon (GAC).** Petroleum and other organic contaminants are removed by adsorption. GAC is a highly porous agent formed by "activating" wood, coal, or coconut shells with steam: 1 kg of GAC has a surface area of 275 acres!

## Water Softening via Ion Exchange

Water with large amounts of 2+ ions, such as  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ , is called **hard water**. Combined with fatty-acid anions in soap, these cations form solid deposits on clothes, washing machines, and sinks:

When a large amount of  $\text{HCO}_3^-$  is present, the cations form *scale*, a carbonate deposit in boilers and hot-water pipes that interferes with the transfer of heat:

Removing hard-water cations, called **water softening**, is done by exchanging  $\text{Na}^+$  ions for  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  ions. A home system for **ion exchange** contains an insoluble polymer *resin* with bonded

Figure B13.1 The typical steps in municipal water treatment.

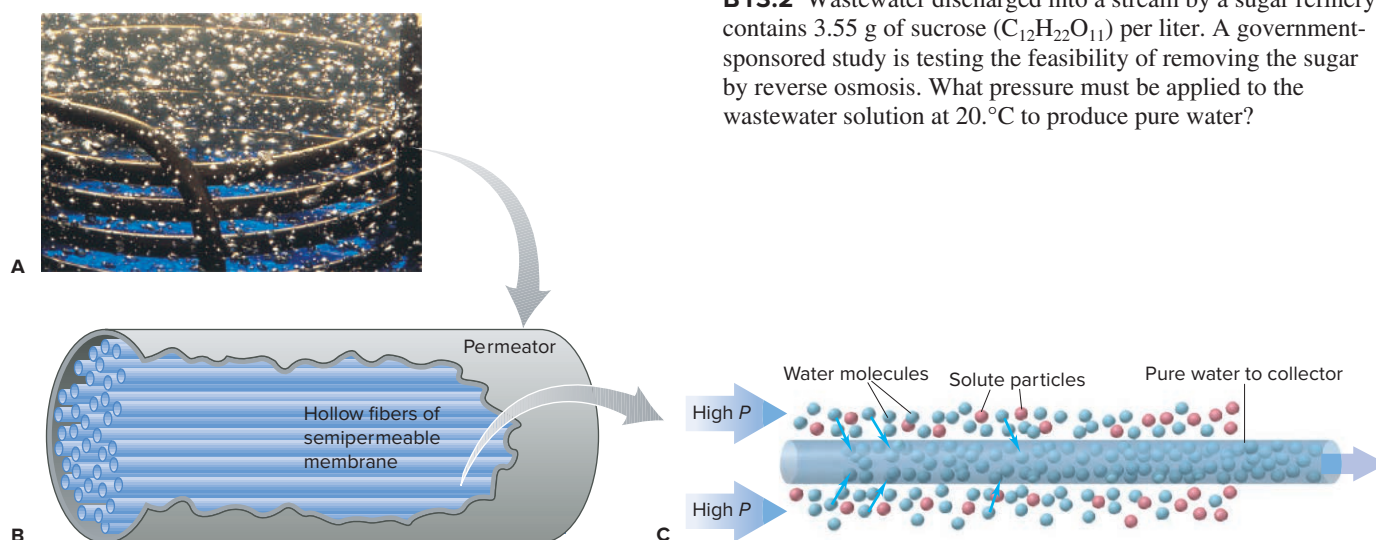

**Figure B13.2** Ion exchange to remove hard-water cations.

anionic groups, such as  $\text{—SO}_3^-$  or  $\text{—COO}^-$ , and  $\text{Na}^+$  ions for charge balance (Figure B13.2). The hard-water cations displace the  $\text{Na}^+$  ions and bind to the anionic groups. When all resin sites are occupied, the resin is regenerated with concentrated  $\text{Na}^+$  solution that exchanges  $\text{Na}^+$  ions for bound  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ .

## Membrane Processes and Reverse Osmosis

Membranes with 0.0001–0.01  $\mu\text{m}$  pores can remove unwanted ions from water. Recall that solutions of different concentrations separated by a semipermeable membrane create osmotic pressure. In **reverse osmosis**, a pressure *greater* than the osmotic pressure is *applied* to the more concentrated solution to force water back through the membrane and filter out ions. In homes, toxic *heavy-metal ions*, such as  $\text{Pb}^{2+}$ ,  $\text{Cd}^{2+}$ , and  $\text{Hg}^{2+}$ , are removed this way. On a large scale, reverse osmosis is used for **desalination**, which can convert seawater (40,000 ppm of ions) to drinking water (400 ppm) (Figure B13.3).

**Figure B13.3** Reverse osmosis to remove ions. **A**, Part of a reverse-osmosis permeator. **B**, Each permeator contains a bundle of hollow fibers of semipermeable membrane. **C**, Pumping seawater at high pressure removes ions, and purer water enters the fibers and is collected.

## Wastewater Treatment

**Wastewater**, used domestic or industrial water, is treated in several ways before being returned to a natural source:

- In *primary* treatment, the water enters a settling basin to remove particles.
- In *biological* treatment, bacteria metabolize organic compounds and are then removed by settling.
- In *advanced* treatment, a process is tailored to remove a specific pollutant. For example, ammonia, which causes excessive growth of plants and algae, is removed in two steps:
  1. *Nitrification*. Certain bacteria oxidize ammonia (electron donor) with  $\text{O}_2$  (electron acceptor) to form nitrate ion:

2. *Denitrification*. Other bacteria oxidize an added compound like methanol ( $\text{CH}_3\text{OH}$ ) using the  $\text{NO}_3^-$ :

Thus, the process converts  $\text{NH}_3$  in wastewater to  $\text{N}_2$ , which is released to the atmosphere.

## Problems

**B13.1** Briefly answer each of the following:

- Why is cake alum [ $\text{Al}_2(\text{SO}_4)_3$ ] added during water purification?
- Why is water that contains large amounts of  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  difficult to use for cleaning?
- What is the meaning of “reverse” in reverse osmosis?
- Why might a water treatment plant use ozone as a disinfectant instead of chlorine?
- How does passing a saturated  $\text{NaCl}$  solution through a “spent” ion-exchange resin regenerate the resin?

**B13.2** Wastewater discharged into a stream by a sugar refinery contains 3.55 g of sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) per liter. A government-sponsored study is testing the feasibility of removing the sugar by reverse osmosis. What pressure must be applied to the wastewater solution at 20.°C to produce pure water?

## CHAPTER REVIEW GUIDE

## Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. The quantitative meaning of solubility (§13.1)
2. The major types of intermolecular forces in solution and their relative strengths (§13.1)
3. How the like-dissolves-like rule depends on intermolecular forces (§13.1)
4. Why gases have relatively low solubilities in water (§13.1)
5. General characteristics of solutions formed by various combinations of gases, liquids, and solids (§13.1)
6. How intermolecular forces stabilize the structures of proteins, the cell membrane, and DNA (§13.2)
7. The enthalpy components of a solution cycle and their effect on  $\Delta H_{\text{soln}}$  (§13.3)
8. The dependence of  $\Delta H_{\text{hydr}}$  on ionic charge density and the factors that determine whether ionic solution processes are exothermic or endothermic (§13.3)
9. The meaning of entropy and how the balance between the change in enthalpy and the change in entropy governs the solution process (§13.3)
10. The distinctions among saturated, unsaturated, and supersaturated solutions, and the equilibrium nature of a saturated solution (§13.4)
11. The relation between temperature and the solubility of solids (§13.4)
12. Why the solubility of gases in water decreases with a rise in temperature (§13.4)
13. The effect of gas pressure on solubility and its quantitative expression as Henry's law (§13.4)
14. The meaning of molarity, molality, mole fraction, and parts by mass or by volume of a solution, and how to convert among them (§13.5)
15. The distinction between electrolytes and nonelectrolytes in solution (§13.6)

16. The four colligative properties and their dependence on number of dissolved particles (§13.6)
17. Ideal solutions and the importance of Raoult's law (§13.6)
18. How the phase diagram of a solution differs from that of the pure solvent (§13.6)
19. Why the vapor over a solution of a volatile nonelectrolyte is richer in the more volatile component (§13.6)
20. Why strong electrolyte solutions are not ideal and the meanings of the van't Hoff factor and ionic atmosphere (§13.6)
21. How particle size distinguishes suspensions, colloids, and solutions (§13.7)
22. How colloidal behavior is demonstrated by the Tyndall effect and Brownian motion (§13.7)

## Master These Skills

1. Predicting relative solubilities from intermolecular forces (SP 13.1)
2. Calculating the heat of solution for an ionic compound (SP 13.2)
3. Using Henry's law to calculate the solubility of a gas (SP 13.3)
4. Expressing concentration in terms of molality, parts by mass, parts by volume, and mole fraction (SPs 13.4, 13.5)
5. Interconverting among the various terms for expressing concentration (SP 13.6)
6. Using Raoult's law to calculate the vapor pressure lowering of a solution (SP 13.7)
7. Determining boiling and freezing points of a solution (SP 13.8)
8. Using a colligative property to calculate the molar mass of a solute (SP 13.9)
9. Calculating the composition of vapor over a solution of volatile nonelectrolyte (§13.6)
10. Calculating the van't Hoff factor ( $i$ ) from the magnitude of a colligative property (§13.6)
11. Using a depiction to determine colligative properties (SP 13.10)

## Key Terms

Page numbers appear in parentheses.

alloy (538)	freezing point depression ( $\Delta T_f$ ) (561)	mass percent [% (w/w)] (554)	soap (541)
amino acid (539)	hard water (570)	miscible (534)	solubility ( $S$ ) (534)
boiling point elevation ( $\Delta T_b$ ) (559)	heat of hydration ( $\Delta H_{\text{hydr}}$ ) (545)	molality ( $m$ ) (553)	solute (534)
charge density (545)	heat of solution ( $\Delta H_{\text{soln}}$ ) (544)	mole fraction ( $X$ ) (554)	solvation (545)
colligative property (557)	Henry's law (551)	mononucleotide (543)	solvent (534)
colloid (568)	hydration (545)	nonelectrolyte (557)	supersaturated solution (549)
desalination (571)	hydration shell (534)	nucleic acid (542)	suspension (568)
dipole-induced dipole force (535)	ideal solution (558)	osmosis (562)	Tyndall effect (569)
double helix (543)	ion exchange (570)	osmotic pressure ( $\Pi$ ) (562)	unsaturated solution (549)
electrolyte (557)	ionic atmosphere (565)	protein (539)	vapor pressure lowering ( $\Delta P$ ) (558)
entropy ( $S$ ) (547)	ion-induced dipole force (534)	Raoult's law (558)	volume percent [% (v/v)] (554)
fractional distillation (564)	like-dissolves-like rule (534)	reverse osmosis (571)	wastewater (571)
	lipid bilayer (542)	saturated solution (549)	water softening (570)
		semipermeable membrane (562)	

## Key Equations and Relationships

Page numbers appear in parentheses.

**13.1** Dividing the general heat of solution into component enthalpies (544):

$$\Delta H_{\text{soln}} = \Delta H_{\text{solute}} + \Delta H_{\text{solvent}} + \Delta H_{\text{mix}}$$

**13.2** Dividing the heat of solution of an ionic compound in water into component enthalpies (545):

$$\Delta H_{\text{soln}} = \Delta H_{\text{lattice}} + \Delta H_{\text{hydr of the ions}}$$

**13.3** Relating gas solubility to its partial pressure (Henry's law) (551):

$$S_{\text{gas}} = k_{\text{H}} \times P_{\text{gas}}$$

**13.4** Defining concentration in terms of molarity (552):

$$\text{Molarity } (M) = \frac{\text{amount (mol) of solute}}{\text{volume (L) of solution}}$$

**13.5** Defining concentration in terms of molality (553):

$$\text{Molality } (m) = \frac{\text{amount (mol) of solute}}{\text{mass (kg) of solvent}}$$

**13.6** Defining concentration in terms of mass percent (554):

$$\text{Mass percent } [\% \text{ (w/w)}] = \frac{\text{mass of solute}}{\text{mass of solution}} \times 100$$

**13.7** Defining concentration in terms of volume percent (554):

$$\text{Volume percent } [\% \text{ (v/v)}] = \frac{\text{volume of solute}}{\text{volume of solution}} \times 100$$

**13.8** Defining concentration in terms of mole fraction (554):

$$\text{Mole fraction } (X) = \frac{\text{amount (mol) of solute}}{\text{amount (mol) of solute} + \text{amount (mol) of solvent}}$$

**13.9** Expressing the relationship between the vapor pressure of solvent above a solution and its mole fraction in the solution (Raoult's law) (558):

$$P_{\text{solvent}} = X_{\text{solvent}} \times P_{\text{solvent}}^{\circ}$$

**13.10** Calculating the vapor pressure lowering due to solute (558):

$$\Delta P = X_{\text{solute}} \times P_{\text{solvent}}^{\circ}$$

**13.11** Calculating the boiling point elevation of a solution (560):

$$\Delta T_{\text{b}} = K_{\text{b}} m$$

**13.12** Calculating the freezing point depression of a solution (561):

$$\Delta T_{\text{f}} = K_{\text{f}} m$$

**13.13** Calculating the osmotic pressure of a solution (562):

$$\Pi = \frac{n_{\text{solute}}}{V_{\text{soln}}} RT = MRT$$

### BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

**13.1A** (a) 1-Butanol has one —OH group/molecule, while 1,4-butanediol has two —OH groups/molecule. 1,4-Butanediol is more soluble in water because it can form more H bonds. (b) Chloroform is more soluble in water because of dipole-dipole forces between the polar  $\text{CHCl}_3$  molecules and water. The forces between nonpolar  $\text{CCl}_4$  molecules and water are weaker dipole-induced dipole forces, which do not effectively replace H bonds between water molecules.

**13.1B** (a) Chloroform dissolves more chloromethane due to similar dipole-dipole forces between the polar molecules of these two substances.  $\text{CH}_3\text{Cl}$  molecules do not exhibit H bonding and so do not effectively replace H bonds between methanol molecules. (b) Hexane dissolves more pentanol due to dispersion forces between the hydrocarbon chains in each molecule.

**13.2A** From Equation 13.2, we have

$$\begin{aligned} \Delta H_{\text{soln}} \text{ of } \text{KNO}_3 &= \Delta H_{\text{lattice}} \text{ of } \text{KNO}_3 \\ &\quad + (\Delta H_{\text{hydr}} \text{ of } \text{K}^+ + \Delta H_{\text{hydr}} \text{ of } \text{NO}_3^-) \\ 34.89 \text{ kJ/mol} &= 685 \text{ kJ/mol} + (\Delta H_{\text{hydr}} \text{ of } \text{K}^+ + \Delta H_{\text{hydr}} \text{ of } \text{NO}_3^-) \\ \Delta H_{\text{hydr}} \text{ of } \text{K}^+ + \Delta H_{\text{hydr}} \text{ of } \text{NO}_3^- &= 34.89 \text{ kJ/mol} - 685 \text{ kJ/mol} \\ &= -650. \text{ kJ/mol} \end{aligned}$$

**13.2B** From Equation 13.2, we have

$$\begin{aligned} \Delta H_{\text{soln}} \text{ of } \text{NaCN} &= \Delta H_{\text{lattice}} \text{ of } \text{NaCN} \\ &\quad + (\Delta H_{\text{hydr}} \text{ of } \text{Na}^+ + \Delta H_{\text{hydr}} \text{ of } \text{CN}^-) \\ 1.21 \text{ kJ/mol} &= 766 \text{ kJ/mol} + (-410. \text{ kJ/mol} + \Delta H_{\text{hydr}} \text{ of } \text{CN}^-) \\ \Delta H_{\text{hydr}} \text{ of } \text{CN}^- &= 1.21 \text{ kJ/mol} - 766 \text{ kJ/mol} + 410. \text{ kJ/mol} \\ &= -355 \text{ kJ/mol} \end{aligned}$$

**13.3A** The partial pressure of  $\text{N}_2$  in air is the volume percent divided by 100 times the total pressure (Dalton's law, Section 5.4):  
 $P_{\text{N}_2} = 0.78 \times 1 \text{ atm} = 0.78 \text{ atm}.$

$$\begin{aligned} S_{\text{gas}} &= k_{\text{H}} \times P_{\text{gas}} \\ S_{\text{N}_2} &= (7 \times 10^{-4} \text{ mol/L} \cdot \text{atm})(0.78 \text{ atm}) \\ &= 5 \times 10^{-4} \text{ mol/L} \end{aligned}$$

**13.3B** In a mixture of gases, the volume percent of a gas divided by 100 times the total pressure equals the gas's partial pressure (Dalton's law, Section 5.4):

$$P_{\text{gas}} = 0.40 \times 1.2 \text{ atm} = 0.48 \text{ atm}.$$

$$k_{\text{H}} = \frac{S_{\text{gas}}}{P_{\text{gas}}} = \frac{1.2 \times 10^{-2} \text{ mol/L}}{0.48 \text{ atm}} = 2.5 \times 10^{-2} \text{ mol/L} \cdot \text{atm}$$

**13.4A** Convert mass (g) of ethanol to kg, multiply by the molality to obtain amount (mol) of glucose, and then multiply amount (mol) of glucose by the molar mass to obtain mass of glucose.

$$\begin{aligned} \text{Amount (mol) of glucose} &= 563 \text{ g ethanol} \times \frac{1 \text{ kg}}{10^3 \text{ g}} \times \frac{2.40 \times 10^{-2} \text{ mol glucose}}{1 \text{ kg ethanol}} \\ &= 1.35 \times 10^{-2} \text{ mol glucose} \end{aligned}$$

$$\begin{aligned} \text{Mass (g) glucose} &= 1.35 \times 10^{-2} \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6 \times \frac{180.16 \text{ g } \text{C}_6\text{H}_{12}\text{O}_6}{1 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6} \\ &= 2.43 \text{ g glucose} \end{aligned}$$

**13.4B** Convert mass (g) of  $\text{I}_2$  to amount (mol) and amount (mol) of  $(\text{CH}_3\text{CH}_2)_2\text{O}$  to mass (kg). Then divide moles of  $\text{I}_2$  by kg of  $(\text{CH}_3\text{CH}_2)_2\text{O}$ .

$$\begin{aligned} \text{Amount (mol) of } \text{I}_2 &= 15.20 \text{ g } \text{I}_2 \times \frac{1 \text{ mol } \text{I}_2}{253.8 \text{ g } \text{I}_2} \\ &= 5.989 \times 10^{-2} \text{ mol } \text{I}_2 \end{aligned}$$

$$\begin{aligned} \text{Mass (kg) of } (\text{CH}_3\text{CH}_2)_2\text{O} &= 1.33 \text{ mol } (\text{CH}_3\text{CH}_2)_2\text{O} \times \frac{74.12 \text{ g } (\text{CH}_3\text{CH}_2)_2\text{O}}{1 \text{ mol } (\text{CH}_3\text{CH}_2)_2\text{O}} \times \frac{1 \text{ kg}}{10^3 \text{ g}} \\ &= 9.86 \times 10^{-2} \text{ kg } (\text{CH}_3\text{CH}_2)_2\text{O} \end{aligned}$$

$$\text{Molality } (m) = \frac{5.989 \times 10^{-2} \text{ mol}}{9.86 \times 10^{-2} \text{ kg}} = 0.607 \text{ m}$$

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

(continued)

$$\mathbf{13.5A} \quad \text{Mass \%} = \frac{\text{mass of solute}}{\text{mass of solution}} \times 100$$

$$\text{Mass \% C}_3\text{H}_7\text{OH} = \frac{35.0 \text{ g}}{35.0 \text{ g} + 150. \text{ g}} \times 100 = 18.9 \text{ mass \%}$$

$$\text{Mass \% C}_2\text{H}_5\text{OH} = 100.0 - 18.9 = 81.1 \text{ mass \%}$$

$$X_{\text{C}_3\text{H}_7\text{OH}} = \frac{35.0 \text{ g C}_3\text{H}_7\text{OH} \times \frac{1 \text{ mol C}_3\text{H}_7\text{OH}}{60.09 \text{ g C}_3\text{H}_7\text{OH}}}{\left(35.0 \text{ g C}_3\text{H}_7\text{OH} \times \frac{1 \text{ mol C}_3\text{H}_7\text{OH}}{60.09 \text{ g C}_3\text{H}_7\text{OH}}\right) + \left(150. \text{ g C}_2\text{H}_5\text{OH} \times \frac{1 \text{ mol C}_2\text{H}_5\text{OH}}{46.07 \text{ g C}_2\text{H}_5\text{OH}}\right)} = 0.152$$

$$X_{\text{C}_2\text{H}_5\text{OH}} = 1.000 - 0.152 = 0.848$$

$$\mathbf{13.5B} \quad \text{Total mass (g)} = 1.87 \text{ g} + 27.4 \text{ g} + 4.10 \text{ g} = 33.4 \text{ g}$$

$$\text{Mass \%} = \frac{\text{mass of solute}}{\text{mass of solution}} \times 100$$

$$\text{Mass \% C}_2\text{H}_5\text{OH} = \frac{1.87 \text{ g}}{33.4 \text{ g}} \times 100 = 5.60\%$$

$$\text{Mass \% C}_8\text{H}_{18} = 82.0\%; \text{ mass \% C}_7\text{H}_{16} = 12.3\%$$

$$\begin{aligned} \text{Amount (mol) of C}_2\text{H}_5\text{OH} &= 1.87 \text{ g C}_2\text{H}_5\text{OH} \times \frac{1 \text{ mol C}_2\text{H}_5\text{OH}}{46.07 \text{ g C}_2\text{H}_5\text{OH}} \\ &= 0.0406 \text{ mol C}_2\text{H}_5\text{OH} \end{aligned}$$

$$\text{Amount (mol) of C}_8\text{H}_{18} = 0.240 \text{ mol C}_8\text{H}_{18}$$

$$\text{Amount (mol) of C}_7\text{H}_{16} = 0.0409 \text{ mol C}_7\text{H}_{16}$$

$$\begin{aligned} \text{Total amount (mol)} &= 0.0406 \text{ mol} + 0.240 \text{ mol} + 0.0409 \text{ mol} \\ &= 0.322 \text{ mol} \end{aligned}$$

$$\text{Mole \% C}_2\text{H}_5\text{OH} = \frac{\text{mol C}_2\text{H}_5\text{OH}}{\text{total mol}} \times 100$$

$$\text{Mole \% C}_2\text{H}_5\text{OH} = \frac{0.0406 \text{ mol}}{0.322 \text{ mol}} \times 100 = 12.6\%$$

$$\text{Mole \% C}_8\text{H}_{18} = 74.5\%; \text{ mole \% C}_7\text{H}_{16} = 12.7\%$$

(Slight differences from 100% are due to rounding.)

$$\mathbf{13.6A} \quad \text{There are 11.8 moles of HCl in 1.00 L of solution:}$$

$$\text{Mass (g) of HCl} = 11.8 \text{ mol HCl} \times \frac{36.46 \text{ g HCl}}{1 \text{ mol HCl}} = 430. \text{ g HCl}$$

$$\begin{aligned} \text{Mass (g) of soln} &= 1 \text{ L soln} \times \frac{10^3 \text{ mL soln}}{1 \text{ L soln}} \times \frac{1.190 \text{ g soln}}{1 \text{ mL soln}} \\ &= 1190. \text{ g soln} \end{aligned}$$

$$\begin{aligned} \text{Mass \% HCl} &= \frac{\text{mass of HCl}}{\text{mass of soln}} \times 100 = \frac{430. \text{ g}}{1190. \text{ g}} \times 100 \\ &= 36.1 \text{ mass \% HCl} \end{aligned}$$

$$\begin{aligned} \text{Mass (kg) of H}_2\text{O} &= (1190. \text{ g soln} - 430. \text{ g HCl}) \times \frac{1 \text{ kg}}{1000 \text{ g}} \\ &= 0.760 \text{ kg H}_2\text{O} \end{aligned}$$

$$\text{Molality of HCl} = \frac{\text{mol HCl}}{\text{kg water}} = \frac{11.8 \text{ mol HCl}}{0.760 \text{ kg H}_2\text{O}} = 15.5 \text{ m HCl}$$

$$\begin{aligned} \text{Amount (mol) of H}_2\text{O} &= 760 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}} \\ &= 42.2 \text{ mol H}_2\text{O} \end{aligned}$$

$$X_{\text{HCl}} = \frac{\text{mol HCl}}{\text{mol HCl} + \text{mol H}_2\text{O}} = \frac{11.8 \text{ mol}}{11.8 \text{ mol} + 42.2 \text{ mol}} = 0.219$$

$$\mathbf{13.6B} \quad \text{There are 5.44 moles of CaBr}_2 \text{ in 1 kg (1000 g) of H}_2\text{O:}$$

$$\begin{aligned} \text{Mass (g) of CaBr}_2 &= 5.44 \text{ mol CaBr}_2 \times \frac{199.88 \text{ g CaBr}_2}{1 \text{ mol CaBr}_2} \\ &= 1087 \text{ g CaBr}_2 \end{aligned}$$

$$\text{Mass (g) of soln} = 1087 \text{ g CaBr}_2 + 1000 \text{ g H}_2\text{O} = 2087 \text{ g soln}$$

$$\begin{aligned} \text{Mass \% CaBr}_2 &= \frac{\text{mass of CaBr}_2}{\text{mass of soln}} \times 100 = \frac{1087 \text{ g}}{2087 \text{ g}} \times 100 \\ &= 52.1 \text{ mass \% CaBr}_2 \end{aligned}$$

$$\begin{aligned} \text{Volume (L) of soln} &= 2087 \text{ g soln} \times \frac{1 \text{ mL soln}}{1.70 \text{ g soln}} \\ &\times \frac{1 \text{ L}}{10^3 \text{ mL}} = 1.228 \text{ L soln} \end{aligned}$$

$$\text{Molarity (M)} = \frac{\text{amount (mol) CaBr}_2}{\text{L soln}} = \frac{5.44 \text{ mol CaBr}_2}{1.228 \text{ L}} = 4.43 \text{ M}$$

$$\text{Amount (mol) of H}_2\text{O} = 1000 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}} = 55.5 \text{ mol H}_2\text{O}$$

$$\begin{aligned} \text{Mole \%} &= \frac{\text{amount (mol) CaBr}_2}{\text{amount (mol) CaBr}_2 + \text{amount (mol) H}_2\text{O}} \times 100 \\ &= \frac{5.44 \text{ mol CaBr}_2}{5.44 \text{ mol CaBr}_2 + 55.5 \text{ mol H}_2\text{O}} \times 100 \\ &= 8.93\% \end{aligned}$$

$$\mathbf{13.7A} \quad \text{Find the mole fraction of aspirin and use Equation 13.10:}$$

$$\begin{aligned} \text{Amount (mol) of aspirin} &= 2.00 \text{ g aspirin} \times \frac{1 \text{ mol aspirin}}{180.15 \text{ g aspirin}} \\ &= 0.0111 \text{ mol aspirin} \end{aligned}$$

$$\begin{aligned} \text{Amount (mol) of CH}_3\text{OH} &= 50.0 \text{ g CH}_3\text{OH} \times \frac{1 \text{ mol CH}_3\text{OH}}{32.04 \text{ g CH}_3\text{OH}} \\ &= 1.56 \text{ mol CH}_3\text{OH} \end{aligned}$$

$$\begin{aligned} X_{\text{aspirin}} &= \frac{\text{mol aspirin}}{\text{mol aspirin} + \text{mol CH}_3\text{OH}} = \frac{0.0111 \text{ mol}}{0.0111 \text{ mol} + 1.56 \text{ mol}} \\ &= 0.00707 \end{aligned}$$

$$\Delta P = X_{\text{aspirin}} \times P_{\text{methanol}}^\circ = 0.00707 \times 101 \text{ torr} = 0.714 \text{ torr}$$

**13.7B** Find mole fraction of ethanol, apply Equation 13.9, and convert kPa to torr:

$$\text{Amount (mol) of menthol} = 6.49 \text{ g menthol} \times \frac{1 \text{ mol menthol}}{156.26 \text{ g menthol}} = 0.0415 \text{ mol menthol}$$

$$\text{Amount (mol) of ethanol} = 25.0 \text{ g ethanol} \times \frac{1 \text{ mol ethanol}}{46.07 \text{ g ethanol}} = 0.543 \text{ mol ethanol}$$

$$X_{\text{ethanol}} = \frac{\text{mol of ethanol}}{\text{mol of ethanol} + \text{mol of menthol}} = \frac{0.543 \text{ mol}}{0.543 \text{ mol} + 0.0415 \text{ mol}} = 0.929$$

$$P_{\text{ethanol}} \text{ (kPa)} = X_{\text{ethanol}} \times P_{\text{ethanol}}^{\circ} = 0.929 \times 6.87 \text{ kPa} = 6.38 \text{ kPa}$$

$$P_{\text{ethanol}} \text{ (torr)} = 6.38 \text{ kPa} \times \frac{760 \text{ torr}}{101.325 \text{ kPa}} = 47.9 \text{ torr}$$

**13.8A** Find molality and then apply Equations 13.11 and 13.12:

$$\text{Amount (mol) of } P_4 = 8.44 \text{ g } P_4 \times \frac{1 \text{ mol } P_4}{123.88 \text{ g } P_4} = 0.0681 \text{ mol } P_4$$

$$\text{Molality (} m \text{)} = \frac{\text{amount (mol) } P_4}{\text{mass (kg) } CS_2} = \frac{0.0681 \text{ mol } P_4}{60.0 \text{ g } CS_2 \times \frac{1 \text{ kg}}{10^3 \text{ g}}} = 1.14 \text{ } m$$

$$\Delta T_b = K_b m = 2.34^{\circ}C/m \times 1.14 \text{ } m = 2.67^{\circ}C$$

$$T_{b(\text{solution})} = T_{b(\text{solvent})} + \Delta T_b = 46.2^{\circ}C + 2.67^{\circ}C = 48.9^{\circ}C$$

$$\Delta T_f = K_f m = 3.83^{\circ}C/m \times 1.14 \text{ } m = 4.37^{\circ}C$$

$$T_{f(\text{solution})} = T_{f(\text{solvent})} - \Delta T_f = -111.5^{\circ}C - 4.37^{\circ}C = -115.9^{\circ}C$$

**13.8B** Calculate  $\Delta T_f$  in  $^{\circ}C$  and use Equation 13.12:

$$\Delta T_f = T_{f(\text{solvent})} - T_{f(\text{solution})} = 32.00^{\circ}F - 0.00^{\circ}F = 32.00^{\circ}F \times \frac{5^{\circ}C}{9^{\circ}F} = 17.78^{\circ}C$$

$$\text{Molality of } C_2H_6O_2 = \frac{\Delta T_f}{K_f} = \frac{17.78^{\circ}C}{1.86^{\circ}C/m} = 9.56 \text{ } m$$

$$\begin{aligned} \text{Mass of } C_2H_6O_2 &= 4.00 \text{ kg } H_2O \times \frac{9.56 \text{ mol } C_2H_6O_2}{1 \text{ kg } H_2O} \\ &\quad \times \frac{62.07 \text{ g } C_2H_6O_2}{1 \text{ mol } C_2H_6O_2} = 2370 \text{ g } C_2H_6O_2 \end{aligned}$$

**13.9A** Find the molarity with Equation 13.13, use  $V$  to find the amount (mol), and then use mass to find the molar mass:

$$\begin{aligned} \text{Molarity (} M \text{)} &= \frac{\Pi}{RT} = \frac{8.98 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}}}{\left(0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}}\right) (273.15 \text{ K} + 27.0)} \\ &= 4.79 \times 10^{-4} \text{ mol/L} \end{aligned}$$

$$\begin{aligned} \text{Amount (mol)} &= M \times V = 4.79 \times 10^{-4} \text{ mol/L} \times 0.0120 \text{ L} \\ &= 5.75 \times 10^{-6} \text{ mol} \end{aligned}$$

$$\mathcal{M} = \frac{0.200 \text{ g}}{5.75 \times 10^{-6} \text{ mol}} = 3.48 \times 10^4 \text{ g/mol}$$

**13.9B** Find the molality with Equation 13.12, use the mass of solvent to find the amount (mol) of naphthalene, and then use mass to find the molar mass:

$$\text{Molality} = \frac{\Delta T_f}{K_f} = \frac{5.56^{\circ}C - 4.20^{\circ}C}{4.90^{\circ}C/m} = 0.278 \text{ } m$$

$$\begin{aligned} \text{Amount (mol) of naphthalene} \\ &= 0.200 \text{ kg benzene} \times \frac{0.278 \text{ mol naphthalene}}{1 \text{ kg benzene}} = 0.0556 \text{ mol} \end{aligned}$$

$$\mathcal{M} = \frac{7.01 \text{ g}}{0.0556 \text{ mol}} = 126 \text{ g/mol}$$

**13.10A** (a) Scene B shows separate ions in a  $3 K^+/1 PO_4^{3-}$  ratio.

(b) Find the moles of  $K_3PO_4$  and then the molality of the solution; use Equation 13.11 to find the boiling point:

$$\begin{aligned} \text{Amount (mol) of } K_3PO_4 &= 31.2 \text{ g } K_3PO_4 \times \frac{1 \text{ mol } K_3PO_4}{212.27 \text{ g } K_3PO_4} \\ &= 0.147 \text{ mol } K_3PO_4 \end{aligned}$$

$$\text{Molality (} m \text{)} = \frac{\text{amount (mol) of } K_3PO_4}{\text{mass (kg) of } H_2O} = \frac{0.147 \text{ mol}}{0.0850 \text{ kg}} = 1.73 \text{ } m$$

With  $i = 4$ ,  $\Delta T_b = iK_b m = 4 \times 0.512^{\circ}C/m \times 1.73 \text{ } m = 3.54^{\circ}C$

$$T_{b(\text{solution})} = T_{b(\text{solvent})} + \Delta T_b = 100.00^{\circ}C + 3.54^{\circ}C = 103.54^{\circ}C$$

**13.10B** (a) Find the molarity of the solution and use Equation 13.13; assume  $i = 3$ :

$$\text{Mass of solution} = 100. \text{ g water} + 0.952 \text{ g } MgCl_2 = 100.952 \text{ g}$$

$$\text{Volume of solution} = 100.952 \text{ g} \times \frac{1 \text{ mL}}{1.006 \text{ g}} \times \frac{1 \text{ L}}{10^3 \text{ mL}} = 0.1003 \text{ L}$$

$$\begin{aligned} \text{Amount (mol) of } MgCl_2 &= 0.952 \text{ g } MgCl_2 \\ &\quad \times \frac{1 \text{ mol } MgCl_2}{95.21 \text{ g } MgCl_2} \\ &= 0.0100 \text{ mol } MgCl_2 \end{aligned}$$

$$\text{Molarity} = \frac{0.0100 \text{ mol } MgCl_2}{0.1003 \text{ L soln}} = 9.97 \times 10^{-2} \text{ } M$$

$$\begin{aligned} \text{Osmotic pressure (} \Pi \text{)} &= i(MRT) \\ &= 3(9.97 \times 10^{-2} \text{ mol/L}) \left(0.0821 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}}\right) (293 \text{ K}) \\ &= 7.19 \text{ atm} \end{aligned}$$

(b) Scene C. There is net flow of water from the glucose solution into the  $MgCl_2$  solution since there are fewer particles of solute in the glucose solution ( $i = 1$  for glucose and  $i = 3$  for  $MgCl_2$ ).

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

### Types of Solutions: Intermolecular Forces and Solubility (Sample Problem 13.1)

#### Concept Review Questions

**13.1** Describe how properties of seawater illustrate the two characteristics that define mixtures.

**13.2** What types of intermolecular forces give rise to hydration shells in an aqueous solution of sodium chloride?

**13.3** Acetic acid is miscible with water. Would you expect carboxylic acids with the general formula  $\text{CH}_3(\text{CH}_2)_n\text{COOH}$  to become more or less water soluble as  $n$  increases? Explain.

**13.4** Which would you expect to be more effective as a soap, sodium acetate or sodium stearate? Explain.

**13.5** Hexane and methanol are miscible as gases but only slightly soluble in each other as liquids. Explain.

**13.6** Hydrogen chloride (HCl) gas is much more soluble than propane gas ( $\text{C}_3\text{H}_8$ ) in water, even though HCl has a lower boiling point. Explain.

#### Skill-Building Exercises (grouped in similar pairs)

**13.7** Which gives the more concentrated solution, (a)  $\text{KNO}_3$  in  $\text{H}_2\text{O}$  or (b)  $\text{KNO}_3$  in carbon tetrachloride ( $\text{CCl}_4$ )? Explain.

**13.8** Which gives the more concentrated solution, stearic acid [ $\text{CH}_3(\text{CH}_2)_{16}\text{COOH}$ ] in (a)  $\text{H}_2\text{O}$  or (b)  $\text{CCl}_4$ ? Explain.

**13.9** What is the strongest type of intermolecular force between solute and solvent in each solution?

- (a)  $\text{CsCl}(s)$  in  $\text{H}_2\text{O}(l)$                       (b)  $\text{CH}_3\overset{\text{O}}{\parallel}\text{CCH}_3(l)$  in  $\text{H}_2\text{O}(l)$   
 (c)  $\text{CH}_3\text{OH}(l)$  in  $\text{CCl}_4(l)$

**13.10** What is the strongest type of intermolecular force between solute and solvent in each solution?

- (a)  $\text{Cu}(s)$  in  $\text{Ag}(s)$                               (b)  $\text{CH}_3\text{Cl}(g)$  in  $\text{CH}_3\text{OCH}_3(g)$   
 (c)  $\text{CH}_3\text{CH}_3(g)$  in  $\text{CH}_3\text{CH}_2\text{CH}_2\text{NH}_2(l)$

**13.11** What is the strongest type of intermolecular force between solute and solvent in each solution?

- (a)  $\text{CH}_3\text{OCH}_3(g)$  in  $\text{H}_2\text{O}(l)$                       (b)  $\text{Ne}(g)$  in  $\text{H}_2\text{O}(l)$   
 (c)  $\text{N}_2(g)$  in  $\text{C}_4\text{H}_{10}(g)$

**13.12** What is the strongest type of intermolecular force between solute and solvent in each solution?

- (a)  $\text{C}_6\text{H}_{14}(l)$  in  $\text{C}_8\text{H}_{18}(l)$                               (b)  $\text{H}_2\text{C}=\text{O}(g)$  in  $\text{CH}_3\text{OH}(l)$   
 (c)  $\text{Br}_2(l)$  in  $\text{CCl}_4(l)$

**13.13** Which member of each pair is more soluble in diethyl ether? Why?

- (a)  $\text{NaCl}(s)$  or  $\text{HCl}(g)$                               (b)  $\text{H}_2\text{O}(l)$  or  $\text{CH}_3\overset{\text{O}}{\parallel}\text{C}(l)$   
 (c)  $\text{MgBr}_2(s)$  or  $\text{CH}_3\text{CH}_2\text{MgBr}(s)$

**13.14** Which member of each pair is more soluble in water? Why?

(a)  $\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_3(l)$  or  $\text{CH}_3\text{CH}_2\text{OCH}_3(g)$

(b)  $\text{CH}_2\text{Cl}_2(l)$  or  $\text{CCl}_4(l)$

#### Problems in Context

**13.15** A dictionary definition of *homogeneous* is “uniform in composition throughout.” River water is a mixture of dissolved compounds, such as calcium bicarbonate, and suspended soil particles. Is river water homogeneous? Explain.

**13.16** Gluconic acid is a derivative of glucose used in cleaners and in the dairy and brewing industries. Caproic acid is a carboxylic acid used in the flavoring industry. Although both are six-carbon acids (see structures below), gluconic acid is soluble in water and nearly insoluble in hexane, whereas caproic acid has the opposite solubility behavior. Explain.

### Intermolecular Forces and Biological Macromolecules

#### Concept Review Questions

**13.17** Name three intermolecular forces that stabilize the shape of a soluble, globular protein, and explain how they act.

**13.18** Name three intermolecular forces that stabilize the structure of DNA, and explain how they act.

**13.19** How can relatively weak H bonds hold the double helix together yet allow DNA to function?

**13.20** Is sodium propanoate (the sodium salt of propanoic acid) as effective a soap as sodium stearate (the sodium salt of stearic acid)? Explain.

**13.21** What intermolecular forces stabilize a lipid bilayer?

**13.22** In what way do proteins embedded in a membrane differ structurally from soluble proteins?

**13.23** Histones are proteins that control gene function by attaching through salt links to exterior regions of DNA. Name an amino acid whose side chain is often found on the exterior of histones.

### Why Substances Dissolve: Understanding the Solution Process (Sample Problem 13.2)

#### Concept Review Questions

**13.24** What is the relationship between solvation and hydration?

**13.25** For a general solvent, which enthalpy terms in the thermochemical solution cycle are combined to obtain  $\Delta H_{\text{solvation}}$ ?

- 13.26** (a) What is the charge density of an ion, and what two properties of an ion affect it?  
 (b) Arrange the following in order of increasing charge density:

(c) How do the two properties in part (a) affect the ionic heat of hydration,  $\Delta H_{\text{hydr}}$ ?

**13.27** For  $\Delta H_{\text{soln}}$  to be very small, what quantities must be nearly equal in magnitude? Will their signs be the same or opposite?

**13.28** Water is added to a flask containing solid  $\text{NH}_4\text{Cl}$ . As the salt dissolves, the solution becomes colder.

- (a) Is the dissolving of  $\text{NH}_4\text{Cl}$  exothermic or endothermic?  
 (b) Is the magnitude of  $\Delta H_{\text{lattice}}$  for  $\text{NH}_4\text{Cl}$  larger or smaller than the combined  $\Delta H_{\text{hydr}}$  values of its ions? Explain.  
 (c) Given the answer to part (a), why does  $\text{NH}_4\text{Cl}$  dissolve in water?

**13.29** An ionic compound has a highly negative  $\Delta H_{\text{soln}}$  in water. Would you expect it to be very soluble or nearly insoluble in water? Explain in terms of enthalpy and entropy changes.

### Skill-Building Exercises (grouped in similar pairs)

**13.30** Sketch an enthalpy diagram for the process of dissolving  $\text{KCl}(s)$  in  $\text{H}_2\text{O}$  (endothermic).

**13.31** Sketch an enthalpy diagram for the process of dissolving  $\text{NaI}(s)$  in  $\text{H}_2\text{O}$  (exothermic).

**13.32** Which ion in each pair has greater charge density? Explain.

- (a)  $\text{Na}^+$  or  $\text{Cs}^+$       (b)  $\text{Sr}^{2+}$  or  $\text{Rb}^+$       (c)  $\text{Na}^+$  or  $\text{Cl}^-$   
 (d)  $\text{O}^{2-}$  or  $\text{F}^-$       (e)  $\text{OH}^-$  or  $\text{SH}^-$       (f)  $\text{Mg}^{2+}$  or  $\text{Ba}^{2+}$   
 (g)  $\text{Mg}^{2+}$  or  $\text{Na}^+$       (h)  $\text{NO}_3^-$  or  $\text{CO}_3^{2-}$

**13.33** Which ion has the lower ratio of charge to volume? Explain.

- (a)  $\text{Br}^-$  or  $\text{I}^-$       (b)  $\text{Sc}^{3+}$  or  $\text{Ca}^{2+}$       (c)  $\text{Br}^-$  or  $\text{K}^+$   
 (d)  $\text{S}^{2-}$  or  $\text{Cl}^-$       (e)  $\text{Sc}^{3+}$  or  $\text{Al}^{3+}$       (f)  $\text{SO}_4^{2-}$  or  $\text{ClO}_4^-$   
 (g)  $\text{Fe}^{3+}$  or  $\text{Fe}^{2+}$       (h)  $\text{Ca}^{2+}$  or  $\text{K}^+$

**13.34** Which ion of each pair in Problem 13.32 has the *larger*  $\Delta H_{\text{hydr}}$ ?

**13.35** Which ion of each pair in Problem 13.33 has the *smaller*  $\Delta H_{\text{hydr}}$ ?

**13.36** (a) Use the following data to calculate the combined heat of hydration for the ions in potassium bromate ( $\text{KBrO}_3$ ):

$$\Delta H_{\text{lattice}} = 745 \text{ kJ/mol} \quad \Delta H_{\text{soln}} = 41.1 \text{ kJ/mol}$$

(b) Which ion contributes more to the answer for part (a)? Why?

**13.37** (a) Use the following data to calculate the combined heat of hydration for the ions in sodium acetate ( $\text{NaC}_2\text{H}_3\text{O}_2$ ):

$$\Delta H_{\text{lattice}} = 763 \text{ kJ/mol} \quad \Delta H_{\text{soln}} = 17.3 \text{ kJ/mol}$$

(b) Which ion contributes more to the answer for part (a)? Why?

**13.38** State whether the entropy of the system increases or decreases in each of the following processes:

- (a) Gasoline burns in a car engine.  
 (b) Gold is extracted and purified from its ore.  
 (c) Ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) dissolves in 1-propanol ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ ).

**13.39** State whether the entropy of the system increases or decreases in each of the following processes:

- (a) Pure gases are mixed to prepare an anesthetic.  
 (b) Electronic-grade silicon is prepared from sand.  
 (c) Dry ice (solid  $\text{CO}_2$ ) sublimates.

### Problems in Context

**13.40** Besides being used in black-and-white film, silver nitrate ( $\text{AgNO}_3$ ) is used similarly in forensic science. The  $\text{NaCl}$  left behind in the sweat of a fingerprint is treated with  $\text{AgNO}_3$  solution to form  $\text{AgCl}$ . This precipitate is developed to show the black-and-white fingerprint pattern. Given that  $\Delta H_{\text{lattice}} = 822 \text{ kJ/mol}$  and  $\Delta H_{\text{hydr}} = -799 \text{ kJ/mol}$  for  $\text{AgNO}_3$ , calculate its  $\Delta H_{\text{soln}}$ .

### Solubility as an Equilibrium Process

(Sample Problem 13.3)

### Concept Review Questions

**13.41** You are given a bottle of solid X and three aqueous solutions of X—one saturated, one unsaturated, and one supersaturated. How would you determine which solution is which?

**13.42** Potassium permanganate ( $\text{KMnO}_4$ ) has a solubility of 6.4 g/100 g of  $\text{H}_2\text{O}$  at  $20^\circ\text{C}$  and a curve of solubility vs. temperature that slopes upward to the right. How would you prepare a supersaturated solution of  $\text{KMnO}_4$ ?

**13.43** Why does the solubility of any gas in water decrease with rising temperature?

### Skill-Building Exercises (grouped in similar pairs)

**13.44** For a saturated aqueous solution of each of the following at  $20^\circ\text{C}$  and 1 atm, will the solubility increase, decrease, or stay the same when the indicated change occurs?

- (a)  $\text{O}_2(g)$ , increase  $P$       (b)  $\text{N}_2(g)$ , increase  $V$

**13.45** For a saturated aqueous solution of each of the following at  $20^\circ\text{C}$  and 1 atm, will the solubility increase, decrease, or stay the same when the indicated change occurs?

- (a)  $\text{He}(g)$ , decrease  $T$       (b)  $\text{RbI}(s)$ , increase  $P$

**13.46** The Henry's law constant ( $k_{\text{H}}$ ) for  $\text{O}_2$  in water at  $20^\circ\text{C}$  is  $1.28 \times 10^{-3} \text{ mol/L} \cdot \text{atm}$ .

(a) How many grams of  $\text{O}_2$  will dissolve in 2.50 L of  $\text{H}_2\text{O}$  that is in contact with pure  $\text{O}_2$  at 1.00 atm?

(b) How many grams of  $\text{O}_2$  will dissolve in 2.50 L of  $\text{H}_2\text{O}$  that is in contact with air, where the partial pressure of  $\text{O}_2$  is 0.209 atm?

**13.47** Argon makes up 0.93% by volume of air. Calculate its solubility (mol/L) in water at  $20^\circ\text{C}$  and 1.0 atm. The Henry's law constant for Ar under these conditions is  $1.5 \times 10^{-3} \text{ mol/L} \cdot \text{atm}$ .

### Problems in Context

**13.48** Caffeine is about 10 times as soluble in hot water as in cold water. A chemist puts a hot-water extract of caffeine into an ice bath, and some caffeine crystallizes. Is the remaining solution saturated, unsaturated, or supersaturated?

**13.49** The partial pressure of  $\text{CO}_2$  gas above the liquid in a bottle of champagne at  $20^\circ\text{C}$  is 5.5 atm. What is the solubility of  $\text{CO}_2$  in champagne? Assume Henry's law constant is the same for champagne as for water: at  $20^\circ\text{C}$ ,  $k_{\text{H}} = 3.7 \times 10^{-2} \text{ mol/L} \cdot \text{atm}$ .

**13.50** Respiratory problems are treated with devices that deliver air with a higher partial pressure of  $\text{O}_2$  than normal air. Why?

**Concentration Terms**

(Sample Problems 13.4 to 13.6)

**Concept Review Questions**

**13.51** Explain the difference between molarity and molality. Under what circumstances would molality be a more accurate measure of the concentration of a prepared solution than molarity? Why?

**13.52** Which way of expressing concentration includes (a) volume of solution; (b) mass of solution; (c) mass of solvent?

**13.53** A solute has a solubility in water of 21 g/kg water. Is this value the same as 21 g/kg solution? Explain.

**13.54** You want to convert among molarity, molality, and mole fraction of a solution. You know the masses of solute and solvent and the volume of solution. Is this enough information to carry out all the conversions? Explain.

**13.55** When a solution is heated, which ways of expressing concentration change in value? Which remain unchanged? Explain.

**Skill-Building Exercises (grouped in similar pairs)**

**13.56** Calculate the molarity of each aqueous solution:

- (a) 32.3 g of table sugar ( $C_{12}H_{22}O_{11}$ ) in 100. mL of solution  
 (b) 5.80 g of  $LiNO_3$  in 505 mL of solution

**13.57** Calculate the molarity of each aqueous solution:

- (a) 0.82 g of ethanol ( $C_2H_5OH$ ) in 10.5 mL of solution  
 (b) 1.27 g of gaseous  $NH_3$  in 33.5 mL of solution

**13.58** Calculate the molarity of each aqueous solution:

- (a) 78.0 mL of 0.240  $M$   $NaOH$  diluted to 0.250 L with water  
 (b) 38.5 mL of 1.2  $M$   $HNO_3$  diluted to 0.130 L with water

**13.59** Calculate the molarity of each aqueous solution:

- (a) 25.5 mL of 6.25  $M$   $HCl$  diluted to 0.500 L with water  
 (b) 8.25 mL of  $2.00 \times 10^{-2} M$   $KI$  diluted to 12.0 mL with water

**13.60** How would you prepare the following aqueous solutions?

- (a) 365 mL of  $8.55 \times 10^{-2} M$   $KH_2PO_4$  from solid  $KH_2PO_4$   
 (b) 465 mL of 0.335  $M$   $NaOH$  from 1.25  $M$   $NaOH$

**13.61** How would you prepare the following aqueous solutions?

- (a) 2.5 L of 0.65  $M$   $NaCl$  from solid  $NaCl$   
 (b) 15.5 L of 0.3  $M$  urea [ $(NH_2)_2C=O$ ] from 2.1  $M$  urea

**13.62** How would you prepare the following aqueous solutions?

- (a) 1.40 L of 0.288  $M$   $KBr$  from solid  $KBr$   
 (b) 255 mL of 0.0856  $M$   $LiNO_3$  from 0.264  $M$   $LiNO_3$

**13.63** How would you prepare the following aqueous solutions?

- (a) 57.5 mL of  $1.53 \times 10^{-3} M$   $Cr(NO_3)_3$  from solid  $Cr(NO_3)_3$   
 (b)  $5.8 \times 10^3 m^3$  of 1.45  $M$   $NH_4NO_3$  from 2.50  $M$   $NH_4NO_3$

**13.64** Calculate the molality of the following:

- (a) A solution containing 85.4 g of glycine ( $NH_2CH_2COOH$ ) dissolved in 1.270 kg of  $H_2O$   
 (b) A solution containing 8.59 g of glycerol ( $C_3H_8O_3$ ) in 77.0 g of ethanol ( $C_2H_5OH$ )

**13.65** Calculate the molality of the following:

- (a) A solution containing 174 g of  $HCl$  in 757 g of  $H_2O$   
 (b) A solution containing 16.5 g of naphthalene ( $C_{10}H_8$ ) in 53.3 g of benzene ( $C_6H_6$ )

**13.66** What is the molality of a solution consisting of 44.0 mL of benzene ( $C_6H_6$ ;  $d = 0.877 g/mL$ ) in 167 mL of hexane ( $C_6H_{14}$ ;  $d = 0.660 g/mL$ )?

**13.67** What is the molality of a solution consisting of 2.66 mL of carbon tetrachloride ( $CCl_4$ ;  $d = 1.59 g/mL$ ) in 76.5 mL of methylene chloride ( $CH_2Cl_2$ ;  $d = 1.33 g/mL$ )?

**13.68** How would you prepare the following aqueous solutions?

- (a)  $3.10 \times 10^2 g$  of 0.125  $m$  ethylene glycol ( $C_2H_6O_2$ ) from ethylene glycol and water  
 (b) 1.20 kg of 2.20 mass %  $HNO_3$  from 52.0 mass %  $HNO_3$

**13.69** How would you prepare the following aqueous solutions?

- (a) 1.50 kg of 0.0355  $m$  ethanol ( $C_2H_5OH$ ) from ethanol and water  
 (b) 445 g of 13.0 mass %  $HCl$  from 34.1 mass %  $HCl$

**13.70** A solution contains 0.35 mol of isopropanol ( $C_3H_7OH$ ) dissolved in 0.85 mol of water.

- (a) What is the mole fraction of isopropanol?  
 (b) The mass percent?  
 (c) The molality?

**13.71** A solution contains 0.100 mol of  $NaCl$  dissolved in 8.60 mol of water.

- (a) What is the mole fraction of  $NaCl$ ?  
 (b) The mass percent?  
 (c) The molality?

**13.72** What mass of cesium bromide must be added to 0.500 L of water ( $d = 1.00 g/mL$ ) to produce a 0.400  $m$  solution? What are the mole fraction and the mass percent of  $CsBr$ ?

**13.73** What are the mole fraction and the mass percent of a solution made by dissolving 0.30 g of  $KI$  in 0.400 L of water ( $d = 1.00 g/mL$ )?

**13.74** Calculate the molality, molarity, and mole fraction of  $NH_3$  in ordinary household ammonia, which is an 8.00 mass % aqueous solution ( $d = 0.9651 g/mL$ ).

**13.75** Calculate the molality, molarity, and mole fraction of  $FeCl_3$  in a 28.8 mass % aqueous solution ( $d = 1.280 g/mL$ ).

**Problems in Context**

**13.76** Wastewater from a cement factory contains 0.25 g of  $Ca^{2+}$  ions and 0.056 g of  $Mg^{2+}$  ions per 100.0 L of solution. The solution density is 1.001 g/mL. Calculate the  $Ca^{2+}$  and  $Mg^{2+}$  concentrations in ppm (by mass).

**13.77** An automobile antifreeze mixture is made by mixing equal volumes of ethylene glycol ( $d = 1.114 g/mL$ ;  $\mathcal{M} = 62.07 g/mol$ ) and water ( $d = 1.00 g/mL$ ) at  $20^\circ C$ . The density of the mixture is 1.070 g/mL. Express the concentration of ethylene glycol as:

- (a) Volume percent    (b) Mass percent    (c) Molarity  
 (d) Molality    (e) Mole fraction

**Colligative Properties of Solutions**

(Sample Problems 13.7 to 13.10)

**Concept Review Questions**

**13.78** The chemical formula of a solute does *not* affect the extent of the solution's colligative properties. What characteristic of a solute *does* affect these properties? Name a physical property of a solution that *is* affected by the chemical formula of the solute.

**13.79** What is a nonvolatile nonelectrolyte? Why is using this type of solute the simplest way to demonstrate colligative properties?

**13.80** In what sense is a strong electrolyte "strong"? What property of a substance makes it a strong electrolyte?

**13.81** Express Raoult's law in words. Is Raoult's law valid for a solution of a volatile solute? Explain.

**13.82** What are the most important differences between the phase diagram of a pure solvent and the phase diagram of a solution of that solvent?

**13.83** Is the composition of the vapor at the top of a fractionating column different from the composition at the bottom? Explain.

**13.84** Is the boiling point of 0.01 *m* KF(aq) higher or lower than that of 0.01 *m* glucose(aq)? Explain.

**13.85** Which aqueous solution has a boiling point closer to its predicted value, 0.050 *m* NaF or 0.50 *m* KCl? Explain.

**13.86** Which aqueous solution has a freezing point closer to its predicted value, 0.01 *m* NaBr or 0.01 *m* MgCl<sub>2</sub>? Explain.

**13.87** The freezing point depression constants of the solvents cyclohexane and naphthalene are 20.1°C/*m* and 6.94°C/*m*, respectively. Which solvent would give a more accurate result if you are using freezing point depression to determine the molar mass of a substance that is soluble in either one? Why?

### Skill-Building Exercises (grouped in similar pairs)

**13.88** Classify each substance as a strong electrolyte, weak electrolyte, or nonelectrolyte:

- (a) Hydrogen chloride (HCl)                      (b) Potassium nitrate (KNO<sub>3</sub>)  
(c) Glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>)                              (d) Ammonia (NH<sub>3</sub>)

**13.89** Classify each substance as a strong electrolyte, weak electrolyte, or nonelectrolyte:

- (a) Sodium permanganate (NaMnO<sub>4</sub>)  
(b) Acetic acid (CH<sub>3</sub>COOH)  
(c) Methanol (CH<sub>3</sub>OH)  
(d) Calcium acetate [Ca(C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>)<sub>2</sub>]

**13.90** How many moles of solute particles are present in 1 L of each of the following aqueous solutions?

- (a) 0.3 *M* KBr                                      (b) 0.065 *M* HNO<sub>3</sub>  
(c) 10<sup>-4</sup> *M* KHSO<sub>4</sub>                                (d) 0.06 *M* ethanol (C<sub>2</sub>H<sub>5</sub>OH)

**13.91** How many moles of solute particles are present in 1 mL of each of the following aqueous solutions?

- (a) 0.02 *M* CuSO<sub>4</sub>                                (b) 0.004 *M* Ba(OH)<sub>2</sub>  
(c) 0.08 *M* pyridine (C<sub>5</sub>H<sub>5</sub>N)              (d) 0.05 *M* (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub>

**13.92** Which solution has the lower freezing point?

- (a) 11.0 g of CH<sub>3</sub>OH in 100. g of H<sub>2</sub>O *or*  
22.0 g of CH<sub>3</sub>CH<sub>2</sub>OH in 200. g of H<sub>2</sub>O  
(b) 20.0 g of H<sub>2</sub>O in 1.00 kg of CH<sub>3</sub>OH *or*  
20.0 g of CH<sub>3</sub>CH<sub>2</sub>OH in 1.00 kg of CH<sub>3</sub>OH

**13.93** Which solution has the higher boiling point?

- (a) 38.0 g of C<sub>3</sub>H<sub>8</sub>O<sub>3</sub> in 250. g of ethanol *or*  
38.0 g of C<sub>2</sub>H<sub>6</sub>O<sub>2</sub> in 250. g of ethanol  
(b) 15 g of C<sub>2</sub>H<sub>6</sub>O<sub>2</sub> in 0.50 kg of H<sub>2</sub>O *or*  
15 g of NaCl in 0.50 kg of H<sub>2</sub>O

**13.94** Rank the following aqueous solutions in order of increasing (a) osmotic pressure; (b) boiling point; (c) freezing point; (d) vapor pressure at 50°C:

- (I) 0.100 *m* NaNO<sub>3</sub>  
(II) 0.100 *m* glucose  
(III) 0.100 *m* CaCl<sub>2</sub>

**13.95** Rank the following aqueous solutions in order of decreasing (a) osmotic pressure; (b) boiling point; (c) freezing point; (d) vapor pressure at 298 K:

- (I) 0.04 *m* urea [(NH<sub>2</sub>)<sub>2</sub>C=O]  
(II) 0.01 *m* AgNO<sub>3</sub>  
(III) 0.03 *m* CuSO<sub>4</sub>

**13.96** Calculate the vapor pressure of a solution of 34.0 g of glycerol (C<sub>3</sub>H<sub>8</sub>O<sub>3</sub>) in 500.0 g of water at 25°C. The vapor pressure of water at 25°C is 23.76 torr. (Assume ideal behavior.)

**13.97** Calculate the vapor pressure of a solution of 0.39 mol of cholesterol in 5.4 mol of toluene at 32°C. Pure toluene has a vapor pressure of 41 torr at 32°C. (Assume ideal behavior.)

**13.98** What is the freezing point of 0.251 *m* urea in water?

**13.99** What is the boiling point of 0.200 *m* lactose in water?

**13.100** The boiling point of ethanol (C<sub>2</sub>H<sub>5</sub>OH) is 78.5°C. What is the boiling point of a solution of 6.4 g of vanillin (*M* = 152.14 g/mol) in 50.0 g of ethanol (*K<sub>b</sub>* of ethanol = 1.22°C/*m*)?

**13.101** The freezing point of benzene is 5.5°C. What is the freezing point of a solution of 5.00 g of naphthalene (C<sub>10</sub>H<sub>8</sub>) in 444 g of benzene (*K<sub>f</sub>* of benzene = 4.90°C/*m*)?

**13.102** What is the minimum mass of ethylene glycol (C<sub>2</sub>H<sub>6</sub>O<sub>2</sub>) that must be dissolved in 14.5 kg of water to prevent the solution from freezing at -12.0°F? (Assume ideal behavior.)

**13.103** What is the minimum mass of glycerol (C<sub>3</sub>H<sub>8</sub>O<sub>3</sub>) that must be dissolved in 11.0 mg of water to prevent the solution from freezing at -15°C? (Assume ideal behavior.)

**13.104** A small protein has a molar mass of 1.50 × 10<sup>4</sup> g/mol. What is the osmotic pressure exerted at 24.0°C by 25.0 mL of an aqueous solution that contains 37.5 mg of the protein?

**13.105** At 37°C, 0.30 *M* sucrose has about the same osmotic pressure as blood. What is the osmotic pressure of blood?

**13.106** A solution made by dissolving 31.7 g of an unknown compound in 150. g of water freezes at -1.15°C. What is the molar mass of the compound?

**13.107** A 125-mL sample of an aqueous solution of the protein ovalbumin from chicken egg white contains 1.31 g of the dissolved protein and has an osmotic pressure of 4.32 torr at 25°C. What is the molar mass of ovalbumin?

**13.108** Assuming ideal behavior, find the freezing point of a solution made by dissolving 13.2 g of ammonium phosphate in 45.0 g of water.

**13.109** Assuming ideal behavior, find the boiling point of a solution made by dissolving 32.8 g of calcium nitrate in 108 g of water.

**13.110** Calculate the molality and van't Hoff factor (*i*) for the following aqueous solutions:

- (a) 1.00 mass % NaCl, freezing point = -0.593°C  
(b) 0.500 mass % CH<sub>3</sub>COOH, freezing point = -0.159°C

**13.111** Calculate the molality and van't Hoff factor (*i*) for the following aqueous solutions:

- (a) 0.500 mass % KCl, freezing point = -0.234°C  
(b) 1.00 mass % H<sub>2</sub>SO<sub>4</sub>, freezing point = -0.423°C

## Problems in Context

**13.112** In a study designed to prepare new gasoline-resistant coatings, a polymer chemist dissolves 6.053 g of poly(vinyl alcohol) in enough water to make 100.0 mL of solution. At 25°C, the osmotic pressure of this solution is 0.272 atm. What is the molar mass of the polymer sample?

**13.113** The U.S. Food and Drug Administration lists dichloromethane (CH<sub>2</sub>Cl<sub>2</sub>) and carbon tetrachloride (CCl<sub>4</sub>) among the many cancer-causing chlorinated organic compounds. What are the partial pressures of these substances in the vapor above a solution of 1.60 mol of CH<sub>2</sub>Cl<sub>2</sub> and 1.10 mol of CCl<sub>4</sub> at 23.5°C? The vapor pressures of pure CH<sub>2</sub>Cl<sub>2</sub> and CCl<sub>4</sub> at 23.5°C are 352 torr and 118 torr, respectively. (Assume ideal behavior.)

## The Structure and Properties of Colloids

## Concept Review Questions

**13.114** Is the fluid inside a bacterial cell considered a solution, a colloid, or both? Explain.

**13.115** What type of colloid is each of the following?

- (a) Milk (b) Fog (c) Shaving cream

**13.116** What is Brownian motion, and what causes it?

**13.117** In a movie theater, you can see the beam of projected light. What phenomenon does this exemplify? Why does it occur?

**13.118** Why don't soap micelles coagulate and form large globules? Is soap more effective in freshwater or in seawater? Why?

## Comprehensive Problems

**13.119** The three aqueous ionic solutions represented below have total volumes of 25. mL for A, 50. mL for B, and 100. mL for C. If each sphere represents 0.010 mol of ions, calculate:

- (a) the total molarity of ions for each solution;  
 (b) the highest molarity of solute;  
 (c) the lowest molality of solute (assuming the solution densities are equal);  
 (d) the highest osmotic pressure (assuming ideal behavior).

**13.120** An aqueous solution is 10.0% glucose by mass ( $d = 1.039$  g/mL at 20°C). Calculate its freezing point, boiling point at 1 atm, and osmotic pressure.

**13.121** Because zinc has nearly the same atomic radius as copper ( $d = 8.95$  g/cm<sup>3</sup>), zinc atoms substitute for some copper atoms in the many types of brass. Calculate the density of the brass with (a) 10.0 atom % Zn and (b) 38.0 atom % Zn.

**13.122** Gold occurs in seawater at an average concentration of  $1.1 \times 10^{-2}$  ppb. How many liters of seawater must be processed to recover 1 troy ounce of gold, assuming 81.5% efficiency ( $d$  of seawater = 1.025 g/mL; 1 troy ounce = 31.1 g)?

**13.123** Use atomic properties to explain why xenon is 11 times as soluble as helium in water at 0°C on a mole basis.

**13.124** Which of the following best represents a molecular-scale view of an ionic compound in aqueous solution? Explain.

**13.125** Four 0.50 *m* aqueous solutions are depicted below. Assume that the solutions behave ideally.

- (a) Which has the highest boiling point?  
 (b) Which has the lowest freezing point?  
 (c) Can you determine which one has the highest osmotic pressure? Explain.

**13.126** Thermal pollution from industrial wastewater causes the temperature of river or lake water to rise, which can affect fish survival as the concentration of dissolved O<sub>2</sub> decreases. Use the following data to find the molarity of O<sub>2</sub> at each temperature (assume the solution density is the same as water).

Temperature (°C)	Solubility of O <sub>2</sub> (mg/kg H <sub>2</sub> O)	Density of H <sub>2</sub> O (g/mL)
0.0	14.5	0.99987
20.0	9.07	0.99823
40.0	6.44	0.99224

**13.127** Pyridine (right) is an essential portion of many biologically active compounds, such as nicotine and vitamin B<sub>6</sub>. Like ammonia, it has a nitrogen with a lone pair, which makes it act as a weak base. Because it is miscible in a wide range of solvents, from water to benzene, pyridine is one of the most important bases and solvents in organic syntheses. Account for its solubility behavior in terms of intermolecular forces.

**13.128** A chemist is studying small organic compounds to evaluate their potential for use as an antifreeze. When 0.243 g of a compound is dissolved in 25.0 mL of water, the freezing point of the solution is -0.201°C.

- (a) Calculate the molar mass of the compound ( $d$  of water = 1.00 g/mL).  
 (b) Analysis shows that the compound is 53.31 mass % C and 11.18 mass % H, the remainder being O. Determine the empirical and molecular formulas of the compound.  
 (c) Draw a Lewis structure for a compound with this formula that forms H bonds and another for one that does not.

**13.129** Air in a smoky bar contains  $4.0 \times 10^{-6}$  mol/L of CO. What mass of CO is inhaled by a bartender who respirates at a rate of 11 L/min during an 8.0-h shift?

**13.130** Is 50% by mass of methanol dissolved in ethanol different from 50% by mass of ethanol dissolved in methanol? Explain.

**13.131** Three gaseous mixtures of  $N_2$  (blue),  $Cl_2$  (green), and Ne (purple) are depicted below.

(a) Which has the smallest mole fraction of  $N_2$ ?

(b) Which have the same mole fraction of Ne?

(c) Rank all three in order of increasing mole fraction of  $Cl_2$ .

**13.132** A water treatment plant needs to attain a fluoride concentration of  $4.50 \times 10^{-5}$  M in the drinking water it produces.

(a) What mass of NaF must be added to 5000. L of water in a blending tank?

(b) What mass per day of fluoride is ingested by a person who drinks 2.0 L of this water?

**13.133** Four U tubes each have distilled water in the right arm, a solution in the left arm, and a semipermeable membrane between the arms.

(a) If the solute is KCl, which solution is most concentrated?

(b) If each solute is different but all the solutions have the same molarity, which contains the smallest number of dissolved ions?

**13.134**  $\beta$ -Pinene ( $C_{10}H_{16}$ ) and  $\alpha$ -terpineol ( $C_{10}H_{18}O$ ) are used in cosmetics to provide a “fresh pine” scent. At 367 K, the pure substances have vapor pressures of 100.3 torr and 9.8 torr, respectively. What is the composition of the vapor (in terms of mole fractions) above a solution containing equal masses of these compounds at 367 K? (Assume ideal behavior.)

**13.135** A solution of 1.50 g of solute dissolved in 25.0 mL of  $H_2O$  at  $25^\circ C$  has a boiling point of  $100.45^\circ C$ .

(a) What is the molar mass of the solute if it is a nonvolatile nonelectrolyte and the solution behaves ideally ( $d$  of  $H_2O$  at  $25^\circ C = 0.997$  g/mL)?

(b) Conductivity measurements show that the solute is ionic with general formula  $AB_2$  or  $A_2B$ . What is the molar mass if the solution behaves ideally?

(c) Analysis indicates that the solute has an empirical formula of  $CaN_2O_6$ . Explain the difference between the actual formula mass and that calculated from the boiling point elevation.

(d) Find the van't Hoff factor ( $i$ ) for this solution.

**13.136** A pharmaceutical preparation made with ethanol ( $C_2H_5OH$ ) is contaminated with methanol ( $CH_3OH$ ). A sample of vapor above the liquid mixture contains a 97/1 mass ratio of  $C_2H_5OH$  to  $CH_3OH$ . What is the mass ratio of these alcohols in the liquid mixture? At the temperature of the liquid mixture, the vapor pressures of  $C_2H_5OH$  and  $CH_3OH$  are 60.5 torr and 126.0 torr, respectively.

**13.137** Water treatment plants commonly use chlorination to destroy bacteria. A byproduct is chloroform ( $CHCl_3$ ), a suspected carcinogen, produced when HOCl, formed by reaction of  $Cl_2$  and water, reacts with dissolved organic matter. The United States, Canada, and the World Health Organization have set a limit of 100. ppb of  $CHCl_3$  in drinking water. Convert this concentration into molarity, molality, mole fraction, and mass percent.

**13.138** A saturated  $Na_2CO_3$  solution is prepared, and a small excess of solid is present (white pile in beaker). A seed crystal of  $Na_2^{14}CO_3$  ( $^{14}C$  is a radioactive isotope of  $^{12}C$ ) is added (small red piece), and the radioactivity is measured over time.

(a) Would you expect radioactivity in the solution? Explain.

(b) Would you expect radioactivity in all the solid or just in the seed crystal? Explain.

**13.139** A biochemical engineer isolates a bacterial gene fragment and dissolves a 10.0-mg sample in enough water to make 30.0 mL of solution. The osmotic pressure of the solution is 0.340 torr at  $25^\circ C$ .

(a) What is the molar mass of the gene fragment?

(b) If the solution density is 0.997 g/mL, how large is the freezing point depression for this solution ( $K_f$  of water =  $1.86^\circ C/m$ )?

**13.140** A river is contaminated with 0.65 mg/L of dichloroethylene ( $C_2H_2Cl_2$ ). What is the concentration (in ng/L) of dichloroethylene at  $21^\circ C$  in the air breathed by a person swimming in the river ( $k_H$  for  $C_2H_2Cl_2$  in water is  $0.033$  mol/L·atm)?

**13.141** At an air-water interface, fatty acids such as oleic acid lie in a one-molecule-thick layer (a monolayer), with the heads in the water and the tails perpendicular in the air. When 2.50 mg of oleic acid is placed on a water surface, it forms a circular monolayer 38.6 cm in diameter. Find the surface area (in  $cm^2$ ) occupied by one molecule ( $M$  of oleic acid = 283 g/mol).

**13.142** A simple device used for estimating the concentration of total dissolved solids in an aqueous solution works by measuring the electrical conductivity of the solution. The method assumes that equal concentrations of different solids give approximately the same conductivity, and that the conductivity is proportional to concentration. The table below gives some actual electrical conductivities (in arbitrary units) for solutions of selected solids at the indicated concentrations (in ppm by mass):

Sample	Conductivity		
	0 ppm	$5.00 \times 10^3$ ppm	$10.00 \times 10^3$ ppm
$CaCl_2$	0.0	8.0	16.0
$K_2CO_3$	0.0	7.0	14.0
$Na_2SO_4$	0.0	6.0	11.0
Seawater (dilute)	0.0	8.0	15.0
Sucrose ( $C_{12}H_{22}O_{11}$ )	0.0	0.0	0.0
Urea [( $NH_2$ ) $_2$ C=O]	0.0	0.0	0.0

(a) How reliable are these measurements for estimating concentrations of dissolved solids?

(b) For what types of substances might this method have a large error? Why?

(c) Based on this method, an aqueous  $CaCl_2$  solution has a conductivity of 14.0 units. Calculate its mole fraction and molality.

**13.143** Two beakers are placed in a closed container (*left*). One beaker contains water, the other a concentrated aqueous sugar solution. With time, the solution volume increases and the water volume decreases (*right*). Explain on the molecular level.

**13.144** The release of volatile organic compounds into the atmosphere is regulated to limit ozone formation. In a laboratory simulation, 5% of the ethanol in a liquid detergent is released. Thus, a “down-the-drain” factor of 0.05 is used to estimate ethanol emissions from the detergent. The  $k_H$  values for ethanol and 2-butoxyethanol ( $C_4H_9OCH_2CH_2OH$ ) are  $5 \times 10^{-6} \text{ atm} \cdot \text{m}^3/\text{mol}$  and  $1.6 \times 10^{-6} \text{ atm} \cdot \text{m}^3/\text{mol}$ , respectively.

- Estimate a “down-the-drain” factor for 2-butoxyethanol in the detergent.
- What is the  $k_H$  for ethanol in units of  $\text{L} \cdot \text{atm}/\text{mol}$ ?
- Is the value found in part (b) consistent with a value given as  $0.64 \text{ Pa} \cdot \text{m}^3/\text{mol}$ ?

**13.145** Although other solvents are available, dichloromethane ( $CH_2Cl_2$ ) is still often used to “decaffeinate” drinks because the solubility of caffeine in  $CH_2Cl_2$  is 8.35 times that in water.

- A 100.0-mL sample of cola containing 10.0 mg of caffeine is extracted with 60.0 mL of  $CH_2Cl_2$ . What mass of caffeine remains in the aqueous phase?
- A second identical cola sample is extracted with two successive 30.0-mL portions of  $CH_2Cl_2$ . What mass of caffeine remains in the aqueous phase after each extraction?
- Which approach extracts more caffeine?

**13.146** How would you prepare 250. g of 0.150 *m* aqueous  $NaHCO_3$ ?

**13.147** Tartaric acid occurs in crystalline residues found in wine vats. It is used in baking powders and as an additive in foods. It contains 32.3% by mass carbon and 3.97% by mass hydrogen; the balance is oxygen. When 0.981 g of tartaric acid is dissolved in 11.23 g of water, the solution freezes at  $-1.26^\circ\text{C}$ . Find the empirical and molecular formulas of tartaric acid.

**13.148** Methanol ( $CH_3OH$ ) and ethanol ( $C_2H_5OH$ ) are miscible because the major intermolecular force for each is H bonding. In some methanol-ethanol solutions, the mole fraction of methanol is higher, but the mass percent of ethanol is higher. What is the range of mole fraction of methanol for these solutions?

**13.149** A solution of 5.0 g of benzoic acid ( $C_6H_5COOH$ ) in 100.0 g of carbon tetrachloride has a boiling point of  $77.5^\circ\text{C}$ .

- Calculate the molar mass of benzoic acid in the solution.
- Suggest a reason for the difference between the molar mass based on the formula and that found in part (a). (*Hint*: Consider intermolecular forces in this compound.)

**13.150** Derive a general equation that expresses the relationship between the molarity and the molality of a solution. Why are the numerical values of these two terms approximately equal for very dilute aqueous solutions?

**13.151** A florist prepares a solution of nitrogen-phosphorus fertilizer by dissolving 5.66 g of  $NH_4NO_3$  and 4.42 g of  $(NH_4)_3PO_4$  in enough water to make 20.0 L of solution. What are the molarities of  $NH_4^+$  and of  $PO_4^{3-}$  in the solution?

**13.152** Suppose coal-fired power plants used water in scrubbers to remove  $SO_2$  from smokestack gases (see Chemical Connections, Section 6.6).

- If the partial pressure of  $SO_2$  in the stack gases is  $2.0 \times 10^{-3} \text{ atm}$ , what is the solubility of  $SO_2$  in the scrubber liquid ( $k_H$  for  $SO_2$  in water is  $1.23 \text{ mol/L} \cdot \text{atm}$  at  $200.^\circ\text{C}$ )?
- From your answer to part (a), why are basic solutions, such as limewater slurries [ $Ca(OH)_2$ ], used in scrubbers?

**13.153** Urea is a white crystalline solid used as a fertilizer, in the pharmaceutical industry, and in the manufacture of certain polymer resins. Analysis of urea reveals that, by mass, it is 20.1% carbon, 6.7% hydrogen, 46.5% nitrogen, and the balance oxygen.

- Find the empirical formula of urea.
- A 5.0 g/L solution of urea in water has an osmotic pressure of 2.04 atm, measured at  $25^\circ\text{C}$ . What are the molar mass and molecular formula of urea?

**13.154** The total concentration of dissolved particles in blood is 0.30 *M*. An intravenous (IV) solution must be isotonic with blood, which means it must have the same concentration.

- To relieve dehydration, a patient is given 100. mL/h of IV glucose ( $C_6H_{12}O_6$ ) for 2.5 h. What mass (g) of glucose did she receive?
- If isotonic saline ( $NaCl$ ) is used, what is the molarity of the solution?
- If the patient is given 150. mL/h of IV saline for 1.5 h, how many grams of  $NaCl$  did she receive?

**13.155** Deviations from Raoult’s law lead to the formation of *azeotropes*, constant boiling mixtures that cannot be separated by distillation, making industrial separations difficult. For components A and B, there is a positive deviation if the A-B attraction is less than A-A and B-B attractions (A and B reject each other), and a negative deviation if the A-B attraction is greater than A-A and B-B attractions. If the A-B attraction is nearly equal to the A-A and B-B attractions, the solution obeys Raoult’s law. Explain whether the behavior of each pair of components will be nearly ideal, show a positive deviation, or show a negative deviation:

- Benzene ( $C_6H_6$ ) and methanol
- Water and ethyl acetate
- Hexane and heptane
- Methanol and water
- Water and hydrochloric acid

**13.156** Acrylic acid ( $CH_2=CHCOOH$ ) is a monomer used to make superabsorbent polymers and various compounds for paint and adhesive production. At 1 atm, it boils at  $141.5^\circ\text{C}$  but is prone to polymerization. Its vapor pressure at  $25^\circ\text{C}$  is 4.1 mbar. What pressure (in mmHg) is needed to distill the pure acid at  $65^\circ\text{C}$ ?

**13.157** To effectively stop polymerization, certain inhibitors require the presence of a small amount of  $O_2$ . At equilibrium with 1 atm of air, the concentration of  $O_2$  dissolved in the monomer acrylic acid ( $CH_2=CHCOOH$ ) is  $1.64 \times 10^{-3} \text{ M}$ .

- What is  $k_H$  ( $\text{mol/L} \cdot \text{atm}$ ) for  $O_2$  in acrylic acid?
- If 0.005 atm of  $O_2$  is sufficient to stop polymerization, what is the molarity of  $O_2$ ?
- What is the mole fraction?
- What is the concentration in ppm? (Pure acrylic acid is 14.6 *M*;  $P_{O_2}$  in air is 0.2095 atm.)

**13.158** Volatile organic solvents have been implicated in adverse health effects observed in industrial workers. Greener methods are phasing these solvents out. Rank the solvents in Table 13.6 in terms of increasing volatility.

**13.159** At ordinary temperatures, water is a poor solvent for organic substances. But at high pressure and above 200°C, water develops many properties of organic solvents. Find the minimum pressure needed to maintain water as a liquid at 200.°C ( $\Delta H_{\text{vap}} = 40.7 \text{ kJ/mol}$  at 100°C and 1.00 atm; assume that this value remains constant with temperature).

**13.160** In ice-cream making, the ingredients are kept below 0.0°C in an ice-salt bath.

(a) Assuming that NaCl dissolves completely and forms an ideal solution, what mass of it is needed to lower the melting point of 5.5 kg of ice to  $-5.0^\circ\text{C}$ ?

(b) Given the same assumptions as in part (a), what mass of  $\text{CaCl}_2$  is needed?

**13.161** Perfluorocarbons (PFCs), hydrocarbons with all H atoms replaced by F atoms, have very weak cohesive forces. One interesting consequence of this property is that a live mouse can breathe while submerged in  $\text{O}_2$ -saturated PFCs.

(a) At 298 K, perfluorohexane ( $\text{C}_6\text{F}_{14}$ ,  $M = 338 \text{ g/mol}$  and  $d = 1.674 \text{ g/mL}$ ) in equilibrium with 101,325 Pa of  $\text{O}_2$  has a mole fraction of  $\text{O}_2$  of  $4.28 \times 10^{-3}$ . What is  $k_{\text{H}}$  in  $\text{mol/L}\cdot\text{atm}$ ?

(b) According to one source,  $k_{\text{H}}$  for  $\text{O}_2$  in water at 25°C is 756.7 L·atm/mol. What is the solubility of  $\text{O}_2$  in water at 25°C in ppm?

(c) Rank in descending order the  $k_{\text{H}}$  for  $\text{O}_2$  in water, ethanol,  $\text{C}_6\text{F}_{14}$ , and  $\text{C}_6\text{H}_{14}$ . Explain your ranking.

**13.162** The solubility of  $\text{N}_2$  in blood is a serious problem for divers breathing compressed air (78%  $\text{N}_2$  by volume) at depths greater than 50 ft.

(a) What is the molarity of  $\text{N}_2$  in blood at 1.00 atm?

(b) What is the molarity of  $\text{N}_2$  in blood at a depth of 50. ft?

(c) Find the volume (in mL) of  $\text{N}_2$ , measured at 25°C and 1.00 atm, released per liter of blood when a diver at a depth of 50. ft rises to the surface ( $k_{\text{H}}$  for  $\text{N}_2$  in water at 25°C is  $7.0 \times 10^{-4} \text{ mol/L}\cdot\text{atm}$  and at 37°C is  $6.2 \times 10^{-4} \text{ mol/L}\cdot\text{atm}$ ; assume  $d$  of water is 1.00 g/mL).

**13.163** Figure 12.11 shows the phase changes of pure water. Consider how the diagram would change if air were present at 1 atm and dissolved in the water.

(a) Would the three phases of water still attain equilibrium at some temperature? Explain.

(b) In principle, would that temperature be higher, lower, or the same as the triple point for pure water? Explain.

(c) Would ice sublime at a few degrees below the freezing point under this pressure? Explain.

(d) Would the liquid have the same vapor pressure as that shown in Figure 12.7 at 100°C? At 120°C?

**13.164**  $\text{KNO}_3$ ,  $\text{KClO}_3$ ,  $\text{KCl}$ , and  $\text{NaCl}$  are recrystallized as follows:

*Step 1.* A saturated aqueous solution of the compound is prepared at 50°C.

*Step 2.* The mixture is filtered to remove undissolved compound.

*Step 3.* The filtrate is cooled to 0°C.

*Step 4.* The crystals that form are filtered, dried, and weighed.

(a) Which compound has the highest percent recovery and which the lowest (see Figure 13.19)?

(b) Starting with 100. g of each compound, how many grams of each can be recovered?

**13.165** Eighty proof whiskey is 40% ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) by volume. A man has 7.0 L of blood and drinks 28 mL of the whiskey, of which 22% of the ethanol goes into his blood.

(a) What concentration (in g/mL) of ethanol is in his blood ( $d$  of ethanol = 0.789 g/mL)?

(b) What volume (in mL) of whiskey would raise his blood alcohol level to  $8.0 \times 10^{-4} \text{ g/mL}$ , the level at which a person is considered intoxicated?

**13.166** Soft drinks are canned under 4 atm of  $\text{CO}_2$  and release  $\text{CO}_2$  when the can is opened.

(a) How many moles of  $\text{CO}_2$  are dissolved in 355 mL of soda in a can before it is opened?

(b) After the soda has gone flat?

(c) What volume (in L) would the released  $\text{CO}_2$  occupy at 1.00 atm and 25°C ( $k_{\text{H}}$  for  $\text{CO}_2$  at 25°C is  $3.3 \times 10^{-2} \text{ mol/L}\cdot\text{atm}$ ;  $P_{\text{CO}_2}$  in air is  $4 \times 10^{-4} \text{ atm}$ )?

**13.167** Gaseous  $\text{O}_2$  in equilibrium with  $\text{O}_2$  dissolved in water at 283 K is depicted at right.

(a) Which scene below represents the system at 298 K?

(b) Which scene represents the system when the pressure of  $\text{O}_2$  is increased by half?

# 14

## Periodic Patterns in the Main-Group Elements

### 14.1 Hydrogen, the Simplest Atom

Where Hydrogen Fits in the Periodic Table  
Highlights of Hydrogen Chemistry

## Concepts and Skills to Review Before You Study This Chapter

- › acids, bases, and salts (Section 4.4)
- › redox behavior and oxidation states (Section 4.5)
- › electron configurations (Section 8.2)
- › trends in atomic size, ionization energy, metallic behavior, and electronegativity (Sections 8.3, 8.4, and 9.5)
- › trends in element properties and type of bonding (Sections 8.4 and 9.5)
- › models of ionic, covalent, and metallic bonding (Sections 9.2, 9.3, 9.6, and 12.6)
- › resonance and formal charge (Section 10.1)
- › molecular shape and polarity (Sections 10.2 and 10.3)
- › orbital hybridization and modes of orbital overlap (Sections 11.1 and 11.2)
- › phase changes and phase diagrams, intermolecular forces, and crystalline solids (Sections 12.2, 12.3, and 12.6)

Recurring patterns appear throughout nature, helping us make sense of the diversity in the world around us. Physical patterns we observe in animals and plants give rise to systems of biological classification; patterns within our bodies, such as heartbeats, allow us to monitor health and disease; and astronomical patterns allow us to predict phases of the Moon, eclipses, and comet appearances. For example, astronomers know from studying the periodic pattern of its orbit that Halley's Comet (*see photo*), last seen in 1986, will appear next in 2061. As you'll see in the upcoming discussions, patterns also appear in the atomic, chemical, and physical properties of the elements, which help us make sense of their behavior.

**IN THIS CHAPTER . . .** We apply general ideas of bonding, structure, and reactivity (from Chapters 7–12) to the main-group elements and see how their behavior correlates with their position in the periodic table.

- › We begin with hydrogen, the simplest element, considering its position in the periodic table and examining the three types of hydrides.
- › We then survey Period 2 as an example of the general changes in chemical and physical properties from left to right across the periodic table.
- › We go on to discuss each of the eight families of main-group elements by exploring vertical trends in physical and chemical properties. In the process, we highlight some of the most important elements—boron, carbon, silicon, nitrogen, phosphorus, oxygen, sulfur, and the halogens.

## 14.1 HYDROGEN, THE SIMPLEST ATOM

A hydrogen atom consists of a nucleus with a single positive charge, surrounded by a single electron. Perhaps because of this simple structure, hydrogen may be the most important element of all. In the Sun, hydrogen (H) nuclei combine to form helium (He) nuclei in a process that provides nearly all Earth's energy. About 90% of all the atoms in the universe are H atoms, so it is the most abundant element by far. On Earth, only tiny amounts of the free, diatomic element occur naturally, but hydrogen is abundant in combination with oxygen in water. With a simple structure and low molar mass, nonpolar  $H_2$  is a colorless, odorless gas with extremely weak dispersion forces that result in very low melting ( $-259^\circ\text{C}$ ) and boiling points ( $-253^\circ\text{C}$ ).

### Where Hydrogen Fits in the Periodic Table

Hydrogen has no perfectly suitable position in the periodic table (Figure 14.1). Depending on the property, hydrogen may fit better in Group 1A(1), 4A(14), or 7A(17):

- Like the Group 1A(1) elements, hydrogen has an outer electron configuration of  $ns^1$  and most commonly a +1 oxidation state. However, unlike the alkali metals, hydrogen shares its single valence electron with nonmetals rather than transferring it to them.

1	H			H			H	
2								
3								
4								
5								
6								
7								

Figure 14.1 Where does hydrogen belong?

Moreover, hydrogen has a much higher ionization energy (IE = 1311 kJ/mol) and electronegativity (EN = 2.1) than any of the alkali metals. By comparison, lithium has an IE of only 520 kJ/mol and an EN of 1.0, the highest of the alkali metals.

- *Like the Group 4A(14) elements*, hydrogen's valence level is half-filled, but with only one electron, and it has an ionization energy, electron affinity, electronegativity, and bond energy similar to the values for Group 4A(14).
- *Like the Group 7A(17) elements*, hydrogen occurs as diatomic molecules and fills its outer level either by electron sharing or by gaining one electron from a metal to form a 1<sup>−</sup> ion (hydride, H<sup>−</sup>). However, while the monatomic halide ions (X<sup>−</sup>) are common and stable, H<sup>−</sup> is rare and reactive. Moreover, hydrogen has a lower electronegativity (EN = 2.1) than any of the halogens (whose ENs range from 4.0 to 2.2), and it lacks their three valence electron pairs.

Hydrogen's unique behavior arises from its tiny size. It has a high IE because its electron is very close to the nucleus, with no inner electrons to shield it from the positive charge. And it has a low EN (for a nonmetal) because it has only one proton to attract bonding electrons. In this chapter, H will be discussed as part of either Group 1A(1) or 7A(17) depending on the property being considered.

## Highlights of Hydrogen Chemistry

In Chapters 12 and 13, we discussed the vital importance of H bonding, and in Chapter 22, we'll look at hydrogen's many uses in industry. Elemental hydrogen is very reactive and combines with nearly every other element. It forms three types of hydrides—ionic, covalent, and metallic.

**Ionic (Saltlike) Hydrides** With very reactive metals, such as those in Group 1A(1) and the larger members of Group 2A(2) (Ca, Sr, and Ba), hydrogen forms *saltlike hydrides*—white, crystalline solids composed of the metal cation and the hydride ion:

In water, H<sup>−</sup> is a strong base that pulls H<sup>+</sup> from surrounding H<sub>2</sub>O molecules to form H<sub>2</sub> and OH<sup>−</sup>:

The hydride ion is also a powerful reducing agent; for example, it reduces Ti(IV) to the free metal:

**Covalent (Molecular) Hydrides** Hydrogen reacts with nonmetals to form many *covalent hydrides*, such as CH<sub>4</sub>, PH<sub>3</sub>, H<sub>2</sub>S, and HCl. Most are gases, but many hydrides of boron and carbon are liquids or solids that consist of much larger molecules. In most covalent hydrides, hydrogen has an oxidation number of +1 because the other nonmetal has a higher electronegativity.

Conditions for preparing the covalent hydrides depend on the reactivity of the other nonmetal. For example, with stable, triple-bonded N<sub>2</sub>, hydrogen reacts at high temperatures (~400°C) and pressures (~250 atm), and the reaction needs a catalyst to proceed at any practical speed:

Industrial facilities throughout the world use this reaction to produce millions of tons of ammonia each year for fertilizers, explosives, and synthetic fibers. On the other hand, hydrogen combines rapidly with reactive, single-bonded F<sub>2</sub>, even at extremely low temperatures (−196°C):

**Metallic (Interstitial) Hydrides** Many transition elements form *metallic (interstitial) hydrides*, in which H<sub>2</sub> molecules (and H atoms) occupy the holes in the metal's crystal structure (Figure 14.2). Thus, such hydrides are *not* compounds but gas-solid solutions.

**Figure 14.2** A metallic (interstitial) hydride.

Also, unlike ionic and covalent hydrides, interstitial hydrides, such as  $\text{TiH}_{1.7}$ , typically do not have a specific stoichiometric formula because the metal can incorporate variable amounts of hydrogen, depending on the pressure and temperature. Metallic hydrides cannot serve as “storage containers” for hydrogen fuel in cars; the metals that store the most hydrogen are expensive and heavy and release hydrogen only at very high temperatures. But other systems, including carbon nanotubes, are being studied for this role.

## 14.2 TRENDS ACROSS THE PERIODIC TABLE: THE PERIOD 2 ELEMENTS

Table 14.1 on pages 588–589 presents the main horizontal trends in atomic properties and the physical and chemical properties that emerge from them for the Period 2 elements, lithium through neon. In general, *these trends apply to the other periods as well*. Note the following points:

- Electrons fill the one  $ns$  and the three  $np$  orbitals according to Pauli’s exclusion principle and Hund’s rule.
- As a result of increasing nuclear charge and the addition of electrons to orbitals of the same energy level (same  $n$  value), atomic size generally decreases, whereas first ionization energy and electronegativity generally increase (see bar graphs).
- Metallic character decreases with increasing nuclear charge as elements change from metals to metalloids to nonmetals.
- Reactivity is highest at the left and right ends of the period, except for the inert noble gas, because members of Groups 1A(1) and 7A(17) are only one electron away from attaining a filled outer level.
- Bonding between atoms of an element changes from metallic, to covalent in networks, to covalent in individual molecules, to none (noble gases exist as separate atoms). As expected, physical properties, such as melting point, change abruptly at the network/molecule boundary, which occurs between carbon (solid) and nitrogen (gas).
- Bonding between each element and an active nonmetal changes from ionic, to polar covalent, to covalent. Bonding between each element and an active metal changes from metallic to polar covalent to ionic (see Figure 9.2).
- The acid-base behavior of the common element oxide in water changes from basic to amphoteric to acidic as the bond between the element and oxygen changes from ionic to covalent (see the similar trend for the Period 3 elements in Figure 8.24).
- Reducing strength decreases through the metals, and oxidizing strength increases through the nonmetals. In Period 2, oxidation numbers (O.N.s) equal the A-group number for Li and Be and the A-group number minus 8 for O and F. Boron has several O.N.s, Ne has none, and C and N show all the O.N.s that are possible for their groups.

**The Anomalous Behavior of Period 2 Members** One point that is not made in Table 14.1 is the *anomalous (unrepresentative) behavior specific for the Period 2 elements within their groups*. This behavior arises from the relatively *small atomic size* of these elements and the *small number of orbitals* in their outer energy level.

1. *Anomalous properties of lithium.* In Group 1A(1), Li is the only member that forms a simple oxide and nitride,  $\text{Li}_2\text{O}$  and  $\text{Li}_3\text{N}$ , on reaction with  $\text{O}_2$  and  $\text{N}_2$  in air and the only member that forms molecular compounds with organic halides:

Because of its small size,  $\text{Li}^+$  has a relatively high charge density. Therefore, it can deform nearby electron clouds to a much greater extent than the other Group 1A(1) ions can, which increases orbital overlap and gives many lithium salts significant covalent character. Thus,  $\text{LiCl}$ ,  $\text{LiBr}$ , and  $\text{LiI}$  are much more soluble in polar organic solvents, such as ethanol and acetone, than are the halides of Na and K, because the bond polarity of a lithium halide allows it to interact with these solvents through

Table 14.1

dipole-dipole forces. The small, highly positive  $\text{Li}^+$  makes  $\text{Li}$  salts much less soluble in water than those of  $\text{Na}$  and  $\text{K}$ .

2. *Anomalous properties of beryllium.* Because of the extremely high charge density of  $\text{Be}^{2+}$ , the discrete ion does not exist, and *all Be compounds exhibit covalent bonding*. With only two valence electrons,  $\text{Be}$  does not attain an octet in its simple gaseous compounds (Section 10.1), but this electron deficiency is overcome as the gas condenses.

Consider beryllium chloride ( $\text{BeCl}_2$ ). At temperatures greater than  $900^\circ\text{C}$ , it consists of linear molecules in which two  $sp$  hybrid orbitals hold four electrons around the central  $\text{Be}$  (Figure 14.3A). As the temperature decreases, the molecules bond together, solidifying in long chains with each  $\text{Cl}$  bridging two  $\text{Be}$  atoms. Each  $\text{Be}$  is  $sp^3$  hybridized and has attained an octet (Figure 14.3B).

3. *Anomalous properties of other Period 2 elements.* Boron is the only member of its group to form complex families of compounds with metals and with hydrogen (boranes). Carbon shows extremely unusual behavior: carbon atoms bond to other carbons (and to a small number of other elements) extensively and diversely, giving rise to countless organic compounds. Triple-bonded, unreactive, gaseous nitrogen is very different from its reactive, solid family members. Oxygen, the only gas in its group, is much more reactive than sulfur and the other members. Fluorine is so electronegative that it reacts violently with water, and it is the only member of its group that forms a weak hydrohalic acid,  $\text{HF}$ .

## 14.3 GROUP 1A(1): THE ALKALI METALS

The first group of elements in the periodic table is named for the alkaline (basic) nature of their oxides and for the basic solutions the elements form in water. Group 1A(1) provides the best example of regular trends with no significant exceptions. All the elements in the group—lithium ( $\text{Li}$ ), sodium ( $\text{Na}$ ), potassium ( $\text{K}$ ), rubidium ( $\text{Rb}$ ), cesium ( $\text{Cs}$ ), and rare, radioactive francium ( $\text{Fr}$ )\*—are very reactive metals. The Family Portrait of Group 1A(1) is the first in a series that provides an overview of each of the main groups, summarizing key atomic, physical, and chemical properties.

### Why the Alkali Metals Are Unusual Physically

Alkali metals have some properties that are unique for metals:

- They are unusually soft and can be easily cut with a knife.  $\text{Na}$  has the consistency of cold butter, and  $\text{K}$  can be squeezed like clay.
- Alkali metals have lower melting and boiling points than any other group of metals.  $\text{Li}$  is the only member that melts above  $100^\circ\text{C}$ , and  $\text{Cs}$  melts only a few degrees above room temperature.
- They have lower densities than most metals.  $\text{Li}$  floats on lightweight mineral oil (see photo).

The unusual physical behavior of these metals can be traced to the largest atomic size in their respective periods and to the  $ns^1$  valence electron configuration. Because the single valence electron is relatively far from the nucleus, only weak attractions exist in the solid between the delocalized electrons and the metal-ion cores. Such weak metallic bonding means that the alkali metal crystal structure can be easily deformed or broken down, which results in a soft consistency and low melting point. The low densities of the alkali metals result from their having the lowest molar masses and largest atomic radii (and, thus, volumes) in their periods.

\*Francium is so rare (estimates indicate only 15 g of the element in the top kilometer of Earth's crust) that its properties are largely unknown. Therefore, the discussion of this group mentions it only occasionally.

## KEY ATOMIC PROPERTIES, PHYSICAL PROPERTIES, AND REACTIONS

KEY	Atomic No.	Symbol	Atomic mass	Valence e <sup>-</sup> configuration (Common oxidation states)

## Atomic Properties

Group electron configuration is  $ns^1$ . All members have the +1 oxidation state and form an  $E^+$  ion. Atoms have the largest size and lowest IE and EN in their periods. Down the group, atomic and ionic size increase, while IE and EN decrease.

## Physical Properties

Metallic bonding is relatively weak because there is only one valence electron. Therefore, these metals are soft with relatively low melting and boiling points. These values decrease down the group because larger atom cores attract delocalized electrons less strongly. Large atomic size and low atomic mass result in low density; thus, density generally increases down the group because mass increases more than size.

## Reactions

1. The alkali metals reduce H in  $H_2O$  from the +1 to the 0 oxidation state (E represents any element in the group):

The reaction becomes more vigorous down the group.

2. The alkali metals reduce oxygen, but the product depends on the metal. Li forms the oxide,  $Li_2O$ ; Na forms the peroxide (O.N. of O = -1),  $Na_2O_2$ ; K, Rb, and Cs form the superoxide (O.N. of O =  $-\frac{1}{2}$ ),  $EO_2$ :

In emergency breathing units,  $KO_2$  reacts with  $H_2O$  and  $CO_2$  in exhaled air to release  $O_2$  (Section 22.4).

3. The alkali metals reduce hydrogen to form ionic (saltlike) hydrides:

$NaH$  is an industrial base and reducing agent that is used to prepare other reducing agents, such as  $NaBH_4$ .

4. The alkali metals reduce halogens to form ionic halides:

## Why the Alkali Metals Are So Reactive

The alkali metals are extremely reactive elements. They are *powerful reducing agents*, readily losing an electron and always occurring in nature as 1+ cations rather than as free metals. Some examples of their reactivity follow:

- The alkali metals (E)\* reduce halogens to form ionic solids in highly exothermic reactions:

- They reduce hydrogen in water, reacting vigorously (Rb and Cs explosively) to form H<sub>2</sub> and a metal hydroxide solution (*see photo*):

- They reduce molecular hydrogen to form ionic hydrides:

- They reduce O<sub>2</sub> in air, and thus tarnish rapidly. Because of this reactivity, Na and K are usually kept under mineral oil (an unreactive liquid) in the laboratory, and Rb and Cs are handled with gloves under an inert argon atmosphere.

The *ns*<sup>1</sup> configuration, which is the basis for the physical properties of the alkali metals, is also the basis of their reactivity, as shown in the steps for the reaction between an alkali metal and a nonmetal:

- Atomization: the solid metal separates into gaseous atoms.* The weak metallic bonding leads to *low values for*  $\Delta H_{\text{atom}}$  (the heat needed to convert the solid into individual gaseous atoms), which decrease down the group:

- Ionization: the metal atom transfers its outer electron to the nonmetal.* Alkali metals have *low ionization energies* (the lowest in their periods) and form *cations with small radii* since a great decrease in size occurs when the outer electron is lost: the volume of the Li<sup>+</sup> is about 13% the volume of Li! Thus, Group 1A(1) ions are small spheres with considerable charge density.

- Lattice formation: the resulting cations and anions attract each other to form an ionic solid.* Group 1A(1) salts have *high lattice energies*, which easily overcome the endothermic atomization and ionization steps, because the small cations lie close to the anions. For a given anion, the trend in lattice energy is the inverse of the trend in cation size: *as cation radius increases, lattice energy decreases*. The Group 1A(1) and 2A(2) chlorides exemplify this steady decrease in lattice energy (Figure 14.4).

Despite these strong ionic attractions in the solid, *nearly all Group 1A(1) salts are water soluble*. The attraction between the ions and water molecules creates a highly exothermic heat of hydration ( $\Delta H_{\text{hydr}}$ ), and a large increase in entropy occurs when ions in the organized crystal become dispersed and hydrated in solution; together, these factors outweigh the high lattice energy.

The magnitude of the hydration energy *decreases* as ionic size increases:

Interestingly, the *smaller* ions form larger *hydrated ions*. This size trend is key to the function of nerves, kidneys, and cell membranes because the *sizes* of Na<sup>+</sup>(aq) and K<sup>+</sup>(aq), the most common cations in cell fluids, influence their movement into and out of cells.

Potassium reacting with water.

Figure 14.4 Lattice energies of the Group 1A(1) and 2A(2) chlorides.

## 14.4 GROUP 2A(2): THE ALKALINE EARTH METALS

The Group 2A(2) elements are called *alkaline earth metals* because their oxides give basic (alkaline) solutions and melt at such high temperatures that they remained as solids (“earths”) in the alchemists’ fires. The group is a fascinating collection of

\*Throughout the chapter, we use E to represent any element in a group other than in Group 7A(17), for which the halogens are represented as X.

elements: rare beryllium (Be), common magnesium (Mg) and calcium (Ca), less familiar strontium (Sr) and barium (Ba), and radioactive radium (Ra). The Group 2A(2) Family Portrait (*next page*) presents an overview of these elements.

## How the Alkaline Earth and Alkali Metals Compare Physically

In general terms, the elements in Groups 1A(1) and 2A(2) behave as close cousins physically, with the differences due to the change in outer electron configuration from  $ns^1$  to  $ns^2$ . Two electrons from each alkaline earth atom and one more proton in each nucleus strengthen metallic bonding. The following changes result:

- Melting and boiling points are much higher for Group 2A(2) elements; in fact, they melt at around the same temperatures as the Group 1A(1) elements boil.
- Compared to many transition metals, the alkaline earths are soft and lightweight, but they are harder and denser than the alkali metals.

## How the Alkaline Earth and Alkali Metals Compare Chemically

The second valence electron in an alkaline earth metal lies in the same sublevel as the first and thus it is not shielded very well from the additional nuclear charge, so  $Z_{\text{eff}}$  is greater. As a result, Group 2A(2) elements have smaller atomic radii and higher ionization energies than Group 1A(1) elements. Despite the higher IEs, *all the alkaline earths (except Be) occur as 2+ cations in ionic compounds.* (As we said, Be behaves anomalously because so much energy is needed to remove two electrons from this tiny atom that it never forms discrete  $\text{Be}^{2+}$  ions, and so its bonds are polar covalent.)

Some important chemical properties of Group 2A(2) elements are the following:

1. *Reducing strength.* Like the alkali metals, the alkaline earth metals are *strong reducing agents*:

- Each reduces  $\text{O}_2$  in air to form the oxide (Ba also forms the peroxide,  $\text{BaO}_2$ ).
- Except for Be and Mg, which form adherent oxide coatings, each reduces  $\text{H}_2\text{O}$  at room temperature to form  $\text{H}_2$ .
- Except for Be, each reduces the halogens,  $\text{N}_2$ , and  $\text{H}_2$  to form ionic compounds.

2. *Basicity of oxides.* The oxides are strongly basic (except for amphoteric  $\text{BeO}$ ) and react with acidic oxides to form salts, such as sulfites and carbonates; for example,

Natural carbonates, such as limestone and marble, are major structural materials and the commercial sources for most alkaline earth compounds. Calcium carbonate is heated to obtain calcium oxide (lime); this important industrial compound has essential roles in steelmaking, water treatment, and smokestack scrubbing and is used to make glass, whiten paper, and neutralize acidic soil.

3. *Lattice energies and solubilities.* Lattice energy plays a role in the reactivity of the Group 2A(2) elements and the solubility of their salts in water:

- The elements are reactive because the high lattice energies of their compounds more than compensate for the large total IE required to form 2+ cations (Section 9.2). Because the cations are smaller and doubly charged, their charge densities and lattice energies are much higher than those for salts of Group 1A(1) (see Figure 14.4).
- High lattice energy also leads to lower solubility of Group 2A(2) salts in water. Higher charge density increases heat of hydration, but it increases lattice energy even more. Thus, unlike the corresponding Group 1A(1) compounds, most Group 2A(2) fluorides, carbonates, phosphates, and sulfates have very low solubility.
- Although solubility is limited for many Group 2A(2) compounds, the ion-dipole attractions between 2+ ions and water molecules are so strong that many slightly soluble salts of these elements crystallize as hydrates; two examples are Epsom salt,  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ , used as an aqueous soaking solution for treating inflammation, and gypsum,  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ , used as the bonding material between the paper sheets in wallboard and as the cement in surgical casts.

## KEY ATOMIC PROPERTIES, PHYSICAL PROPERTIES, AND REACTIONS

KEY	Atomic No.	Symbol	Atomic mass	Valence e <sup>-</sup> configuration (Common oxidation states)
4	Be	9.012	2s <sup>2</sup>	(+2)
12	Mg	24.30	3s <sup>2</sup>	(+2)

Be 112	
Mg 160	Mg <sup>2+</sup> 72
Ca 197	Ca <sup>2+</sup> 100
Sr 215	Sr <sup>2+</sup> 118
Ba 222	Ba <sup>2+</sup> 135
Ra (~220)	Ra <sup>2+</sup> 148

## Atomic Properties

Group electron configuration is  $ns^2$  (filled  $ns$  sublevel). All members have the +2 oxidation state and, except for Be, form compounds with an  $E^{2+}$  ion. Atomic and ionic sizes increase down the group but are smaller than for the corresponding 1A(1) elements. IE and EN decrease down the group but are higher than for the corresponding 1A(1) elements.

## Physical Properties

Metallic bonding involves two valence electrons. These metals are still relatively soft but are much harder than the 1A(1) metals. Melting and boiling points generally decrease and densities generally increase down the group. These values are much higher than for 1A(1) elements, and the trend is not as regular.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

## Reactions

1. The metals reduce  $O_2$  to form the oxides:

Ba also forms the peroxide,  $BaO_2$ .

2. The larger metals reduce water to form hydrogen gas:

(E = Ca, Sr, Ba)

Be and Mg form an oxide coating that allows only slight reaction.

3. The metals reduce halogens to form ionic halides:

4. Most of the elements reduce hydrogen to form ionic hydrides:

5. The elements reduce nitrogen to form ionic nitrides:

6. Except for amphoteric  $BeO$ , the element oxides are basic:

$Ca(OH)_2$  is a component of cement and mortar.

7. All carbonates undergo thermal decomposition to the oxide:

This reaction is used to produce  $CaO$  (lime) in huge amounts from naturally occurring limestone.

## Diagonal Relationships: Lithium and Magnesium

One of the clearest ways to see how atomic properties influence chemical behavior is to look at three **diagonal relationships**, similarities between a Period 2 element and one diagonally down and to the right in Period 3.

The first of these occurs between Li and Mg, which have similar atomic and ionic sizes (Figure 14.5). Note that *moving one period down increases atomic (or ionic) size and moving one group to the right decreases it*. The Li radius is 152 pm and that of Mg is 160 pm; the  $\text{Li}^+$  radius is 76 pm and that of  $\text{Mg}^{2+}$  is 72 pm. From similar atomic properties emerge similar chemical properties. Both elements form nitrides with  $\text{N}_2$ , hydroxides and carbonates that decompose easily with heat, organic compounds with a polar covalent metal-carbon bond, and salts with similar solubilities. We'll discuss the relationships between Be and Al and between B and Si in upcoming sections.

	1A (1)	2A (2)	3A (13)	4A (14)

3		Mg	Al	Si

**Figure 14.5** Three diagonal relationships in the periodic table.

## 14.5 GROUP 3A(13): THE BORON FAMILY

The third family of main-group elements contains both familiar and unusual members, which engage in some exotic bonding and have strange physical properties. Boron (B) heads the family, but, as we said, its properties are not representative. Metallic aluminum (Al) has properties more typical of the group, but its great abundance and importance contrast with the rareness of gallium (Ga), indium (In), thallium (Tl), and recently synthesized nihonium (Nh). The atomic, physical, and chemical properties of these elements are summarized in the Group 3A(13) Family Portrait (*next page*).

### How the Transition Elements Influence This Group's Properties

If you look only at the main groups, Group 3A(13), the first of the  $p$  block, seems to be just one group away from Group 2A(2). In Period 4 and higher, however, 10 transition elements ( $d$  block) separate these groups (see Figure 8.10). And an additional 14 inner transition elements ( $f$  block) appear in Periods 6 and 7. Thus, the heavier Group 3A(13) members have nuclei with many more protons, but since  $d$  and  $f$  electrons penetrate very little (Section 8.1), the outer ( $s$  and  $p$ ) electrons of Ga, In, and Tl are poorly shielded from the much higher positive charge. As a result, *these elements have greater  $Z_{\text{eff}}$  than the two lighter members*, and this stronger nuclear pull explains why Ga, In, and Tl have smaller atomic radii and larger ionization energies and electronegativities than expected. This effect is observed in higher groups, too.

Physical properties are influenced by the type of bonding. Boron is a network covalent metalloid—black, hard, and very high melting. The other group members are metals—shiny and relatively soft and low melting. Aluminum's low density and three valence electrons make it an exceptional conductor: for a given mass, aluminum conducts a current twice as effectively as copper. Gallium's metallic bonding gives it the largest liquid temperature range of any element: it melts at skin temperature (*see photo in the Family Portrait*) but does not boil until  $2403^\circ\text{C}$ . The bonding is too weak to keep the Ga atoms fixed when the solid is warmed, but strong enough to keep them from escaping the molten metal until it is very hot.

### Features That First Appear in This Group's Chemical Properties

Looking down Group 3A(13), we see a wide range of chemical behavior:

- Boron, the anomalous member from Period 2, is the only metalloid. It is much less reactive at room temperature than the other members and forms covalent bonds exclusively.
- Although aluminum acts like a metal physically, its halides exist in the gas phase as covalent *dimers*—molecules formed by joining two identical smaller molecules (Figure 14.6)—and its oxide is amphoteric rather than basic.
- Most of the other Group 3A(13) compounds are ionic. However, because the cations of this group are smaller and triply charged, they polarize an anion more effectively than do Group 2A(2) cations, and so their compounds are more covalent.

**Figure 14.6** The dimeric structure of gaseous aluminum chloride.

## KEY ATOMIC PROPERTIES, PHYSICAL PROPERTIES, AND REACTIONS

KEY	Atomic No.	Symbol	Atomic mass	Valence e <sup>-</sup> configuration (Common oxidation states)

170	150

## Atomic Properties

Group electron configuration is  $ns^2np^1$ . All except Tl commonly display the +3 oxidation state. The +1 state becomes more common down the group. Atomic size is smaller and EN is higher than for 2A(2) elements; IE is lower, however, because it is easier to remove an electron from the higher energy  $p$  sublevel. Atomic size, IE, and EN do not change as expected down the group because there are intervening transition and inner transition elements.

## Physical Properties

Bonding changes from network covalent in B to metallic in the rest of the group. Thus, B has a much higher melting point than the others, but there is no overall trend. Boiling points decrease down the group. Densities increase down the group.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

## Reactions

1. The elements react sluggishly, if at all, with water:

Al becomes covered with a layer of  $\text{Al}_2\text{O}_3$  that prevents further reaction.

2. When strongly heated in pure  $\text{O}_2$ , all members form oxides:

Oxide acidity decreases down the group:  $\text{B}_2\text{O}_3$  (weakly acidic) >  $\text{Al}_2\text{O}_3$  >  $\text{Ga}_2\text{O}_3$  >  $\text{In}_2\text{O}_3$  >  $\text{Tl}_2\text{O}$  (strongly basic), and the +1 oxide is more basic than the +3 oxide.

3. All members reduce halogens ( $\text{X}_2$ ):

The  $\text{BX}_3$  compounds are volatile and covalent. Trihalides of Al, Ga, and In are (mostly) ionic solids.

The redox behavior of Group 3A(13) exhibits three features that appear first here, but occur in Groups 4A(14) to 6A(16) as well:

1. *Presence of multiple oxidation states.* Larger members of these groups also have an important oxidation state of +1, *two lower than the A-group number*. The lower state occurs when the atoms lose their  $np$  electrons only, not their two  $ns$  electrons. This fact is often called the *inert-pair effect* (Section 8.4).

2. *Increasing stability of the lower oxidation state.* For these groups, *the lower state becomes more stable going down the group*. In Group 3A(13), for instance, all members exhibit the +3 state, but the +1 state first appears with some compounds of gallium and becomes the only important state of thallium.

3. *Increasing metallic behavior and basicity of oxides.* In general, *oxides of the element in the lower oxidation state are more basic*. Thus, for example, in Group 3A(13),  $\text{In}_2\text{O}$  is more basic than  $\text{In}_2\text{O}_3$ . The reason is that *an element acts more like a metal in its lower state*. In this example, the lower charge of  $\text{In}^+$  does not polarize the  $\text{O}^{2-}$  ion as much as the higher charge of  $\text{In}^{3+}$  does, so the In-to-O bonding is more ionic and the  $\text{O}^{2-}$  ion is more available to act as a base.

## Highlights of Boron Chemistry

Like the other Period 2 elements, the chemical behavior of boron is strikingly different from that of the other members of its group. *All boron compounds are covalent*, and unlike the other Group 3A(13) members, boron forms network covalent compounds or large molecules with metals, H, O, N, and C. The unifying feature of many boron compounds is the element's *electron deficiency*. Boron adopts two strategies to fill its outer level: accepting a bonding pair from an electron-rich atom and forming bridge bonds with an electron-poor atom.

**Accepting a Bonding Pair from an Electron-Rich Atom** In gaseous boron trihalides ( $\text{BX}_3$ ), the B atom is electron deficient, with only six electrons around it (Section 10.1). To attain an octet, the B atom accepts a lone pair (*blue*) from an electron-rich atom and forms a covalent bond:

(Reactions in which one reactant accepts an electron pair from another to form a covalent bond are very common and are known as *Lewis acid-base reactions*. We'll discuss them in Chapters 18 and 23 and see examples of them throughout the rest of the text.)

Similarly, B has only six electrons in boric acid,  $\text{B}(\text{OH})_3$  (sometimes written as  $\text{H}_3\text{BO}_3$ ). In water, the acid itself does not release a proton. Rather, it accepts an electron pair from the O in  $\text{H}_2\text{O}$ , forming a fourth bond and releasing an  $\text{H}^+$  ion:

Boron's outer shell is filled in the wide variety of borate salts, such as the mineral borax (sodium borate),  $\text{Na}_2[\text{B}_4\text{O}_5(\text{OH})_4] \cdot 8\text{H}_2\text{O}$ , used for decades as a household cleaning agent. Strong heating of boric acid (or borate salts) drives off water molecules and gives molten boron oxide:

When mixed with silica ( $\text{SiO}_2$ ), this molten oxide forms borosilicate glass. Its high transparency and small change in size when heated or cooled make borosilicate glass useful in cookware and in lab glassware (*see photo*).

**Forming a Bridge Bond with an Electron-Poor Atom** In elemental boron and its many hydrides (boranes), there is no electron-rich atom to supply boron with electrons. In these substances, boron attains an octet through some unusual bonding. In diborane ( $\text{B}_2\text{H}_6$ ) and many larger boranes, for example, two types of B—H bonds exist. The first type is a normal electron-pair bond. The valence bond picture in Figure 14.7 (*next page*) shows an  $sp^3$  orbital of B overlapping a  $1s$  orbital of H in each of the four terminal B—H bonds, using two of the three electrons in the valence level of each B atom.

**Labware made of borosilicate glass.**

Source: © McGraw-Hill Education. Stephen Frisch, photographer

**Figure 14.7** The two types of covalent bonding in diborane.

The other type of bond is a hydride **bridge bond** (or *three-center, two-electron bond*), in which each  $B-H-B$  grouping is held together by only two electrons. Two  $sp^3$  orbitals, one from each B, overlap an H  $1s$  orbital between them. Two electrons move through this extended bonding orbital—one from one of the B atoms and the other from the H atom—and join the two B atoms via the H-atom bridge. Notice that each B atom is surrounded by eight electrons: four from the two normal  $B-H$  bonds and four from the two  $B-H-B$  bridge bonds with a tetrahedral arrangement around each B atom. In many boranes and in elemental boron (Figure 14.8), one B atom bridges two others in a three-center, two-electron  $B-B-B$  bond.

**Figure 14.8** The boron icosahedron and one of the boranes.

### Diagonal Relationships: Beryllium and Aluminum

Beryllium in Group 2A(2) and aluminum in Group 3A(13) are another pair of diagonally related elements. Both form oxoanions in strong base: beryllate,  $Be(OH)_4^{2-}$ , and aluminate,  $Al(OH)_4^-$ . Both have bridge bonds in their hydrides and chlorides. Both form oxide coatings impervious to reaction with water (which explains aluminum's great use as a structural metal), and both oxides are amphoteric, extremely hard, and high melting. Although the atomic and ionic sizes of these elements differ, the small, highly charged  $Be^{2+}$  and  $Al^{3+}$  ions polarize nearby electron clouds strongly. Therefore, some Al compounds and all Be compounds have significant covalent character.

## 14.6 GROUP 4A(14): THE CARBON FAMILY

The whole range of behavior occurs in Group 4A(14): nonmetallic carbon (C) leads off, followed by the metalloids silicon (Si) and germanium (Ge), then metallic tin (Sn) and lead (Pb), and ending with flerovium (Fl), which was synthesized in 1998. Information about the compounds of C and of Si fills libraries: organic chemistry, most polymer chemistry, and biochemistry are based on carbon, whereas geochemistry and some essential polymer and electronic technologies are based on silicon. The Group 4A(14) Family Portrait summarizes atomic, physical, and chemical properties.

### How Type of Bonding Affects Physical Properties

The elements of Group 4A(14) and their neighbors in Groups 3A(13) and 5A(15) illustrate how some physical properties depend on the type of bonding in an element (Table 14.2). Within Group 4A(14), the large decrease in melting point

Sn 140	Sn <sup>2+</sup> 118
Pb 146	Pb <sup>2+</sup> 119

Atomic Properties

Group electron configuration is ns<sup>2</sup>np<sup>2</sup>. Down the group, the number of oxidation states decreases, and the lower (+2) state becomes more common. Down the group, size increases. Because transition and inner transition elements intervene, IE and EN do not decrease smoothly.

Physical Properties

Trends in properties, such as decreasing hardness and melting point, are due to changes in types of bonding within the solid: covalent network in C, Si, and Ge; metallic in Sn and Pb (see text). Down the group, density increases because of several factors, including differences in crystal packing.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

Reactions

1. The elements are oxidized by halogens:

The +2 halides are more stable for tin and lead, SnX<sub>2</sub> and PbX<sub>2</sub>.

2. The elements are oxidized by O<sub>2</sub>:

Pb forms the +2 oxide, PbO. Oxides become more basic down the group. The reaction of CO<sub>2</sub> and H<sub>2</sub>O provides the weak acidity of natural unpolluted waters:

3. Hydrocarbons react with O<sub>2</sub> to form CO<sub>2</sub> and H<sub>2</sub>O. The reaction for methane is adapted to yield heat or electricity:

4. Silica is reduced to form elemental silicon:

This crude silicon is made ultrapure through zone refining for use in the manufacture of computer chips.

between the network covalent solids C and Si is due to longer, weaker bonds in the Si structure; the large decrease between Ge and Sn is due to the change from covalent network to metallic bonding. Similarly, considering horizontal trends, the large increases in melting point and  $\Delta H_{\text{fus}}$  across a period between Al and Si and between Ga and Ge reflect the change from metallic to covalent network bonding. Note the abrupt rises in the values for these properties from metallic Al, Ga, and Sn to the network covalent metalloids Si, Ge, and Sb, and note the abrupt drops from the covalent networks of C and Si to the individual molecules of N and P in Group 5A(15).

**Allotropism: Different Forms of an Element** Striking variations in physical properties often appear among **allotropes**, different crystalline or molecular forms of a substance. One allotrope is usually more stable than another at a particular pressure and temperature. Group 4A(14) provides the first important examples of allotropism, in the forms of carbon and tin.

Figure 14.9 Phase diagram of carbon.

1. *Allotropes and other structures of carbon.* It is difficult to imagine two substances made entirely of the same atom that are more different than graphite and diamond. Graphite is a black electrical conductor that is soft and “greasy,” whereas diamond is a colorless electrical insulator that is extremely hard. Graphite is the standard state of carbon, the more stable form at ordinary temperature and pressure (Figure 14.9, red dot). Fortunately for jewelry owners, diamond changes to graphite at a negligible rate under normal conditions.

In the mid-1980s, a new allotrope was discovered. Mass spectra of soot showed a soccer ball-shaped molecule of formula  $C_{60}$  (Figure 14.10A). The molecule has also been found in geological samples formed by meteorite impacts, even the one that occurred around the time the dinosaurs became extinct. The molecule was dubbed *buckminsterfullerene* (and called a “buckyball”) after the architect-engineer R. Buckminster Fuller, who designed structures with similar shapes. Excitement rose in 1990, when scientists learned how to prepare enough  $C_{60}$  to study its behavior and applications. Since then, metal atoms have been incorporated in the balls and many different groups (fluorine, hydroxyl

groups, sugars, etc.) have been attached, resulting in compounds with a range of useful properties.

In 1991, scientists passed an electric discharge through graphite rods and obtained extremely thin ( $\sim 1$  nm in diameter) graphite-like tubes with fullerene ends called *nanotubes* (Figure 14.10B; the model shows concentric nanotubes, colored differently, without the fullerene ends). Rigid and, on a mass basis, stronger than steel along their

Figure 14.10 Models of buckminsterfullerene (A), a carbon nanotube (B), and graphene (C).

long axis, they also conduct electricity along this axis because of the delocalized electrons. With applications in nanoscale electronics, energy storage, catalysis, polymers, and medicine, nanotube chemistry is a major area of materials research. Then, in 2010, the Nobel Prize in physics was awarded for studies of a new form of carbon called *graphene*, which exists as extended sheets only one atom thick but has remarkable conductivity and strength (Figure 14.10C).

2. *Allotropes of tin.* Tin has two allotropes. White  $\beta$ -tin is stable at room temperature and above, whereas gray  $\alpha$ -tin is the more stable form below 13°C (56°F). When white tin is kept for long periods at a low temperature, some converts to microcrystals of gray tin. The random formation and growth of these regions of gray tin, which has a different crystal structure, weaken the metal and make it crumble. In the unheated cathedrals of medieval northern Europe, tin pipes of magnificent organs were sometimes destroyed by the “tin disease” caused by this allotropic transition.

## How Bonding Changes in This Group’s Compounds

The Group 4A(14) elements display a wide range of chemical behavior, from the covalent compounds of carbon to the ionic compounds of lead, and the features we saw first in Group 3A(13) appear here as well.

1. *Multiple oxidation states.* All the members have at least two important states (+4 and +2), and carbon has three (+4, +2, and -4).

2. *Increasing stability of lower oxidation state.* Compounds with Si in the +4 state are much more stable than those with Si in the +2 state, whereas compounds with Pb in the +2 state are more stable than those with Pb in the +4 state.

3. *Increasing metallic behavior, ionic bonding, and oxide basicity.* Carbon’s intermediate EN of 2.5 ensures that it always bonds covalently, but the larger members form bonds with increasing ionic character. With nonmetals, Si and Ge form strong polar covalent bonds, such as the Si—O bond, one of the strongest Period 3 bonds (BE = 368 kJ/mol) and responsible for the stability of Earth’s solid surface. Although individual ions of Sn or Pb rarely exist, their bonding with a nonmetal has considerable ionic character. And the bonding becomes more ionic with the metal in the lower oxidation state. Thus, SnCl<sub>2</sub> and PbCl<sub>2</sub> are white, high-melting, water-soluble crystals—typical properties of a salt (Figure 14.11)—whereas SnCl<sub>4</sub> is a volatile, nonpolar liquid, and PbCl<sub>4</sub> is a thermally unstable oil. Similarly, SnO and PbO are more basic than SnO<sub>2</sub> and PbO<sub>2</sub>: because the +2 metals are less able to polarize the oxide ion, the E-to-O bonding is more ionic.

**Figure 14.11** Saltlike +2 chlorides and oily +4 chlorides show the greater metallic character of tin and lead in their lower oxidation state.

## Highlights of Carbon Chemistry

Like the other Period 2 elements, carbon is an anomaly in its group; indeed, it may be an anomaly in the entire periodic table. Carbon forms bonds with the smaller Group 1A(1) and 2A(2) metals, many transition metals, the halogens, and many other metalloids and nonmetals. In addition to the three common oxidation states, carbon exhibits all the others possible for its group, from +4 through -4.

**Figure 14.12** Two of the several million known organic compounds of carbon.

**A**, Acrylonitrile, a precursor of acrylic fibers.  
**B**, Lysine, one of about 20 amino acids that occur in proteins.

**Organic Compounds** Two major properties of carbon give rise to the enormous field of organic chemistry.

1. Carbon forms covalent bonds with other carbon atoms—a process known as *catenation*. As a result of its small size and its capacity for four bonds, carbon can form chains, branches, and rings that lead to myriad structures. Add a lot of H, some O and N, a bit of S, P, halogens, and a few metals, and you have the whole organic world! Figure 14.12 shows two of the several million organic compounds known.

Halogenated organic compounds have major polymer applications, such as poly(vinyl chloride) in plumbing and Teflon in cookware. Some are very long-lived in the environment. PCBs, previously used in electrical equipment, are now banned because they are carcinogenic (Figure 14.13). And Freons, used as cleaners of electronic parts and coolants in air conditioners, are responsible for a severe reduction in Earth's protective ozone layer (Chapter 16).

**Figure 14.13** Two important halogenated organic compounds. **A**, A typical PCB (one of the polychlorinated biphenyls). **B**, Freon-12 ( $\text{CCl}_2\text{F}_2$ ), a chlorofluorocarbon.

2. Carbon has the ability to form multiple bonds. Multiple bonds are common in carbon structures because the C—C bond is short enough for side-to-side overlap of two half-filled  $2p$  orbitals to form  $\pi$  bonds. (In Chapter 15, we discuss how the properties of carbon give rise to the diverse structures and reactivities of organic compounds.)

Because the other Group 4A(4) members are larger, E—E bonds become longer and weaker, so catenation and multiple bonding are much less important down the group.

**Inorganic Compounds** In contrast to its organic compounds, carbon's inorganic compounds are simple.

1. *Carbonates*. Metal carbonates are the main mineral form. Marble, limestone, chalk, coral, and several other types are found in enormous deposits throughout the world. Many of these compounds are remnants of fossilized marine organisms. Carbonates are essential to many industries, and they occur in several common antacids because they react with the HCl in stomach acid:

Identical net ionic reactions with sulfuric and nitric acids protect lakes bounded by limestone deposits from the harmful effects of acid rain.

2. *Oxides*. Unlike the other Group 4A(4) members, which form only solid network covalent or ionic oxides, carbon forms two common gaseous oxides,  $\text{CO}_2$  and  $\text{CO}$ .

- Carbon dioxide is essential to all life: it is the primary source of carbon in plants, through photosynthesis, and in animals who eat the plants. Its aqueous solution is the cause of mild acidity in natural waters. However, its atmospheric buildup from deforestation and excessive use of fossil fuels is severely affecting the global climate through warming.
- Carbon monoxide forms when carbon or its compounds burn in an inadequate supply of  $\text{O}_2$ :

It is a key component of syngas fuels (see Chemical Connections, Chapter 6) and is widely used in the production of methanol, formaldehyde, and other major industrial compounds.  $\text{CO}$  binds strongly to many transition metals. When inhaled in cigarette smoke or polluted air, it enters the blood and binds strongly to the  $\text{Fe(II)}$  in hemoglobin, preventing the normal binding of  $\text{O}_2$ , and to other iron-containing proteins. The cyanide ion ( $\text{CN}^-$ ) is *isoelectronic* with  $\text{CO}$ :

Cyanide binds to many of the same iron-containing proteins and is also toxic.

## Highlights of Silicon Chemistry

To a great extent, the chemistry of silicon is the chemistry of the *silicon-oxygen bond*. Just as carbon forms lengthy  $\text{C}-\text{C}$  chains, the  $-\text{Si}-\text{O}-$  grouping repeats itself almost endlessly in a wide variety of **silicates**, the most important minerals on the planet, and in **silicones**, synthetic polymers that have many applications:

1. *Silicate minerals*. From common sand and clay to semiprecious amethyst and carnelian, silicate minerals are the dominant form of matter in the nonliving world. Oxygen, the most abundant element on Earth, and silicon, the next most abundant, account for four of every five atoms on the surface of the planet!

The silicate building unit is the *orthosilicate grouping*,  $-\text{SiO}_4-$ , a tetrahedral arrangement of four O atoms around the central Si. Several minerals contain  $\text{SiO}_4^{4-}$  ions or small groups of them linked together. The gemstone zircon ( $\text{ZrSiO}_4$ ) contains one unit; hemimorphite [ $\text{Zn}_4(\text{OH})_2\text{Si}_2\text{O}_7 \cdot \text{H}_2\text{O}$ ] contains two units linked through an oxygen corner of each one; and beryl ( $\text{Be}_3\text{Al}_2\text{Si}_6\text{O}_{18}$ ), the major source of beryllium, contains six units joined in a cyclic ion (Figure 14.14).

In extended structures, one of the O atoms links the next  $\text{Si}-\text{O}$  group to form chains, a second one forms crosslinks to neighboring chains to form sheets, and the

**Figure 14.14** Structures of the silicate anions in some minerals.

**Figure 14.15** Quartz is a three-dimensional framework silicate.

Source: © Albert Russ/Shutterstock.com

third forms more crosslinks to create three-dimensional frameworks. Chains of silicate groups compose the asbestos minerals, sheets give rise to talc and mica, and frameworks occur in feldspar and quartz (Figure 14.15).

2. *Silicone polymers.* Unlike the naturally occurring silicates, silicone polymers are manufactured substances that consist of alternating Si and O atoms with two organic groups also bonded to each Si atom in a very long Si—O chain, as in *poly(dimethyl siloxane)*:

Silicones have properties of both plastics and minerals. The organic groups give them the flexibility and weak intermolecular forces between chains that are characteristic of a plastic, while the O—Si—O backbone confers the thermal stability and nonflammability of a mineral. Structural categories similar to those of the silicates can be created by adding various reactants to form silicone chains, sheets, and frameworks. Chains are oily liquids used as lubricants and as components of car polish and makeup. Sheets are components of gaskets, space suits, and contact lenses. Frameworks have uses as laminates on circuit boards, in nonstick cookware, and in artificial skin and bone.

## Diagonal Relationships: Boron and Silicon

Our final diagonal relationship occurs between the semiconducting metalloids boron and silicon. Both B and Si and their mineral oxoanions—borates and silicates—occur in extended covalent networks. Both boric acid [B(OH)<sub>3</sub>] and silicic acid [Si(OH)<sub>4</sub>] are weakly acidic solids that occur as layers held together by widespread H bonding. Their hydrides—the compact boranes and the extended silanes—are both flammable, low-melting compounds that act as reducing agents.

## 14.7 GROUP 5A(15): THE NITROGEN FAMILY

The first two elements of Group 5A(15), gaseous nonmetallic nitrogen (N) and solid nonmetallic phosphorus (P), play major roles in both nature and industry. Below these nonmetals are two metalloids, arsenic (As) and antimony (Sb), followed by the metal bismuth (Bi), and moscovium (Mc), synthesized in 2003. The Group 5A(15) Family Portrait provides an overview.

Observed in experiments at Dubna, Russia, in 2003

Element	Atomic radius (pm)	Ionic radius (pm)
N	75	N <sup>3-</sup> 146
P	110	P <sup>3-</sup> 212
As	120	
Sb	140	
Bi	150	Bi <sup>3+</sup> 103

Atomic Properties

Group electron configuration is ns<sup>2</sup>np<sup>3</sup>. The np sublevel is half-filled, with each p orbital containing one electron (parallel spin). The number of oxidation states decreases down the group, and the lower (+3) state becomes more common. Atomic properties follow generally expected trends. The large (~50%) increase in size from N to P correlates with the much lower IE and EN of P.

Physical Properties

Physical properties reflect the change from individual molecules (N, P) to network covalent solid (As, Sb) to metal (Bi). Thus, melting points increase and then decrease. Large atomic size and low atomic mass result in low density. Because mass increases more than size down the group, the density of the elements as solids increases. The dramatic increase in density from P to As is due to the intervening transition elements.

Reactions

1. Nitrogen is “fixed” industrially in the Haber process:

Further reactions convert NH<sub>3</sub> to NO, NO<sub>2</sub>, and HNO<sub>3</sub> (see text).

Hydrides of some other group members are formed from reaction in water (or with H<sub>3</sub>O<sup>+</sup>) of a metal phosphide, arsenide, and so forth:

2. Halides are formed by direct combination of the elements:

3. Oxoacids are formed from the halides in a reaction with water that is common to many nonmetal halides:

Note that the oxidation number of E does not change.

## The Wide Range of Physical Behavior

Group 5A(15) displays the widest range of physical behavior we've seen so far because of large changes in bonding and intermolecular forces:

- *Nitrogen* is a gas consisting of  $N_2$  molecules with such weak intermolecular forces that the element *boils* more than  $200^\circ\text{C}$  below room temperature.
- *Phosphorus* exists most commonly as tetrahedral  $P_4$  molecules in the solid phase. Because P is heavier and more polarizable than N, it has stronger dispersion forces and melts about  $25^\circ\text{C}$  above room temperature.
- *Arsenic* consists of extended sheets. Each As atom bonds to three others in the sheet, and each sheet exhibits dispersion forces with adjacent sheets, which gives As the highest melting point in the group.
- *Antimony* has a similar covalent network, also resulting in a high melting point.
- *Bismuth* has metallic bonding and thus a lower melting point than As and Sb.

**Two Allotropes of Phosphorus** Phosphorus has several allotropes, which have very different properties. Two major ones are white and red phosphorus:

- *White phosphorus* consists of tetrahedral molecules (Figure 14.16A). It is a low-melting, whitish, waxy solid that is soluble in nonpolar solvents, such as  $CS_2$ . Each P atom uses its half-filled  $3p$  orbitals to bond to the other three; with a small bond angle ( $60^\circ$ ), and thus weak P—P bonds that are easily broken, it is highly reactive (Figure 14.16B).
- *Red phosphorus* is formed by heating the white form in the absence of air. One of the P—P bonds in each tetrahedron breaks, and those  $3p$  orbitals overlap with others to form chains of  $P_4$  units (Figure 14.16C). The chains make the red allotrope much less reactive, high melting, and insoluble.

**Figure 14.16** Two allotropes of phosphorus.

## Patterns in Chemical Behavior

Many of the patterns we saw in Group 4A(14) appear here in the change from non-metallic N to metallic Bi. The great majority of Group 5A(15) compounds have *covalent bonds*. Whereas N can form no more than four bonds, the next three members can form more by expanding their valence levels and using empty  $d$  orbitals.

1. *Formation of ions.* For a Group 5A(15) element to form an ion with a noble gas electron configuration, it must *gain* three electrons, the last two in endothermic steps. Nevertheless, the enormous lattice energy released when such highly charged anions attract cations drives their formation. However, the  $3-$  anion of N occurs only in compounds with active metals, such as  $Li_3N$  and  $Mg_3N_2$  (and the  $3-$  anion of P may occur in  $Na_3P_3 \cdot 5H_2O$ ). Metallic Bi mostly bonds covalently but exists as a cation in a few compounds, such as  $BiF_3$  and  $Bi(NO_3)_3 \cdot 5H_2O$ , through *loss* of its three  $p$  valence electrons.

2. *Oxidation states and basicity of oxides.* As in Groups 3A(13) and 4A(14), the lower oxidation state becomes more prominent down the group: N exhibits every state

possible for a Group 5A(15) element, from +5 to −3; only the +5 and +3 states are common for P, As, and Sb; and +3 is the only common state of Bi. The oxides change from acidic to amphoteric to basic, reflecting the increase in the metallic character of the elements. In addition, the lower oxide of an element is more basic than the higher oxide, reflecting the greater ionic character of its E-to-O bonding.

3. *Formation of hydrides.* All the Group 5A(15) elements form gaseous hydrides of formula  $\text{EH}_3$ . Except for  $\text{NH}_3$ , these are extremely reactive and poisonous and are synthesized by reaction of a metal phosphide, arsenide, and so forth, which acts as a strong base in water or aqueous acid. For example,

Ammonia is made industrially by direct combination of the elements at high pressure and moderately high temperature:

Nitrogen forms a second hydride, hydrazine,  $\text{N}_2\text{H}_4$ . Like  $\text{NH}_3$ , hydrazine is a weak base; it is used to make antituberculin drugs, plant growth regulators, and fungicides.

Molecular properties of the Group 5A(15) hydrides reveal some interesting bonding and structural patterns:

- Despite its much lower molar mass,  $\text{NH}_3$  melts and boils at higher temperatures than the other 5A(15) hydrides, as a result of its *H bonding* (see Figure 12.15).
- Bond angles decrease from  $107.3^\circ$  for  $\text{NH}_3$  to around  $90^\circ$  for the other hydrides, which suggests that the larger atoms use unhybridized *p* orbitals.
- E—H bond lengths increase down the group, so bond strength and thermal stability decrease:  $\text{AsH}_3$  decomposes at  $250^\circ\text{C}$ ,  $\text{SbH}_3$  at  $20^\circ\text{C}$ , and  $\text{BiH}_3$  at  $-45^\circ\text{C}$ .

We'll see these features—H bonding for the smallest member, change in bond angles, change in bond energies—in the hydrides of Group 6A(16) as well.

4. *Types and properties of halides.* The Group 5A(15) elements all form trihalides ( $\text{EX}_3$ ). All except nitrogen form pentafluorides ( $\text{EF}_5$ ), but only a few other pentahalides ( $\text{PCl}_5$ ,  $\text{PBr}_5$ ,  $\text{AsCl}_5$ , and  $\text{SbCl}_5$ ) are known. Nitrogen cannot form pentahalides because it cannot expand its valence level. Most trihalides are prepared by direct combination:

The pentahalides form with excess halogen:

As with the hydrides, thermal stability of the halides decreases as the E—X bond becomes longer; we see this trend easiest if we change the halogen. Among the nitrogen halides, for example,  $\text{NF}_3$  is a stable, rather unreactive gas.  $\text{NCl}_3$  is explosive and reacts rapidly with water. (The chemist who first prepared it lost three fingers and an eye!)  $\text{NBr}_3$  can only be made below  $-87^\circ\text{C}$ .  $\text{NI}_3$  has never been prepared, but an ammoniated product ( $\text{NI}_3 \cdot \text{NH}_3$ ) explodes at the slightest touch. Other Group 5A(15) members show less drastic trends, but stability decreases as the halogen gets larger.

5. *Reaction of halides in water.* In a reaction pattern typical of many nonmetal halides, each 5A(15) halide reacts with water to yield the hydrogen halide and the oxoacid, in which E has the same O.N. as in the original halide. For example,  $\text{PX}_5$  (O.N. of P = +5) produces phosphoric acid (O.N. of P = +5) and  $\text{HX}$ :

## Highlights of Nitrogen Chemistry

The most striking highlight of nitrogen chemistry is the inertness of  $\text{N}_2$ . Even with four-fifths of the atmosphere being  $\text{N}_2$  and the other fifth nearly all  $\text{O}_2$ , it takes the searing temperature caused by lightning to form significant amounts of nitrogen oxides. Although  $\text{N}_2$  is inert at moderate temperatures, it reacts at high temperatures with  $\text{H}_2$ , Li, Group 2A(2) metals, B, Al, C, Si, Ge, and many transition elements. In fact, nearly every element forms bonds to N. Here we focus on the oxides and the oxoacids and their salts.

**Nitrogen Oxides** Nitrogen is remarkable for having six stable oxides, each with a *positive* enthalpy of formation because of the great strength of the  $\text{N}\equiv\text{N}$  bond ( $\text{BE} = 945 \text{ kJ/mol}$ ). Their structures and some properties are shown in Table 14.3. Unlike the hydrides and halides of nitrogen, the oxides are planar. Nitrogen displays all its positive oxidation states in these compounds, and in  $\text{N}_2\text{O}$  and  $\text{N}_2\text{O}_3$ , the two N atoms have different states. Let's highlight the three most important:

1. *Dinitrogen monoxide* ( $\text{N}_2\text{O}$ ; also called *nitrous oxide*) is the dental anesthetic “laughing gas” and the propellant in canned whipped cream. It is a linear molecule with an electronic structure described by three resonance forms (note formal charges):

2. *Nitrogen monoxide* ( $\text{NO}$ ; also called *nitric oxide*) is a molecule with an odd electron and with biochemical functions ranging from neurotransmission to control of blood flow. In Section 11.3, we used MO theory to explain its bonding. The commercial preparation of  $\text{NO}$  occurs as a first step in the production of nitric acid:

Nitrogen monoxide is also produced whenever air is heated to high temperatures, as in a car engine or by lightning during a thunderstorm:

Heating converts  $\text{NO}$  to two other oxides:

**Table 14.3** Structures and Properties of the Nitrogen Oxides

Formula	Name	Space-Filling Model	Lewis Structure	Oxidation State of N	$\Delta H_f^\circ$ (kJ/mol) at 298 K	Comment
$\text{N}_2\text{O}$	Dinitrogen monoxide (nitrous oxide)		$\text{:N}\equiv\text{N}-\ddot{\text{O}}\text{:}$	+1 (0, +2)	82.0	Colorless gas; used as dental anesthetic (“laughing gas”) and aerosol propellant
$\text{NO}$	Nitrogen monoxide (nitric oxide)		$\text{:}\dot{\text{N}}=\ddot{\text{O}}\text{:}$	+2	90.3	Colorless, paramagnetic gas; biochemical messenger; air pollutant
$\text{N}_2\text{O}_3$	Dinitrogen trioxide		$\begin{array}{c} \text{:}\ddot{\text{O}}\text{:} \quad \text{:}\ddot{\text{O}}\text{:} \\ \diagdown \quad \diagup \\ \text{N}-\text{N} \\ \diagup \quad \diagdown \\ \text{:}\ddot{\text{O}}\text{:} \end{array}$	+3 (+2, +4)	83.7	Reddish-brown gas (reversibly dissociates to $\text{NO}$ and $\text{NO}_2$ )
$\text{NO}_2$	Nitrogen dioxide		$\text{:}\ddot{\text{O}}-\dot{\text{N}}=\ddot{\text{O}}\text{:}$	+4	33.2	Orange-brown, paramagnetic gas formed during $\text{HNO}_3$ manufacture; poisonous air pollutant
$\text{N}_2\text{O}_4$	Dinitrogen tetroxide		$\begin{array}{c} \text{:}\ddot{\text{O}}\text{:} \quad \text{:}\ddot{\text{O}}\text{:} \\ \diagdown \quad \diagup \\ \text{N}-\text{N} \\ \diagup \quad \diagdown \\ \text{:}\ddot{\text{O}}\text{:} \quad \text{:}\ddot{\text{O}}\text{:} \end{array}$	+4	9.16	Colorless to yellow liquid (reversibly dissociates to $\text{NO}_2$ )
$\text{N}_2\text{O}_5$	Dinitrogen pentoxide		$\begin{array}{c} \text{:}\ddot{\text{O}}\text{:} \quad \text{:}\ddot{\text{O}}\text{:} \\ \diagdown \quad \diagup \\ \text{N}-\ddot{\text{O}}-\text{N} \\ \diagup \quad \diagdown \\ \text{:}\ddot{\text{O}}\text{:} \quad \text{:}\ddot{\text{O}}\text{:} \end{array}$	+5	11.3	Colorless, volatile solid consisting of $\text{NO}_2^+$ and $\text{NO}_3^-$ ; gas consists of $\text{N}_2\text{O}_5$ molecules

This type of redox reaction is called a **disproportionation**, in which *one substance acts as both the oxidizing and reducing agents*. In the process, an atom with an intermediate oxidation state in the reactant occurs in both lower and higher states in the products: the oxidation state of N in NO (+2) is intermediate between that in  $\text{N}_2\text{O}$  (+1) and that in  $\text{NO}_2$  (+4).

3. *Nitrogen dioxide* ( $\text{NO}_2$ ), a brown poisonous gas, forms to a small extent when NO reacts with additional oxygen:

Like NO,  $\text{NO}_2$  is a molecule with an odd electron, which is more localized on the N atom in this species. Thus,  $\text{NO}_2$  dimerizes reversibly to *dinitrogen tetroxide*:

Thunderstorms form NO and  $\text{NO}_2$  and carry them down to the soil, where they act as natural fertilizers. In urban traffic, however, their formation leads to *photochemical smog* (see photo) in a series of reactions also involving sunlight, ozone ( $\text{O}_3$ ), unburned gasoline, and various other species.

**Nitrogen Oxoacids and Oxoanions** There are two common oxoacids of nitrogen (Figure 14.17):

1. *Nitric acid* ( $\text{HNO}_3$ ) is produced in the *Ostwald process*; we have already seen the first two steps—the oxidations of  $\text{NH}_3$  to NO and of NO to  $\text{NO}_2$ . The final step is a disproportionation, as the oxidation numbers show:

The NO is recycled to make more  $\text{NO}_2$ .

In nitric acid, as in all oxoacids, *the acidic H is attached to one of the O atoms*. When the proton is lost, the trigonal planar nitrate ion is formed (Figure 14.17A). In the laboratory, nitric acid is used as a strong oxidizing acid. The products of its reactions with metals vary with the metal's reactivity and the acid's concentration. In the following examples, notice that *the  $\text{NO}_3^-$  ion is the oxidizing agent*. Nitrate ion that is not reduced is a spectator ion and does not appear in the net ionic equations.

- With an active metal, such as Al, and dilute nitric acid, N is reduced from the +5 state all the way to the  $-3$  state in the ammonium ion,  $\text{NH}_4^+$ :

- With a less reactive metal, such as Cu, and more concentrated acid, N is reduced to the +2 state in NO:

Photochemical smog over Los Angeles, California.

Source: © Daniel Stein/Getty Images RF

**Figure 14.17** The structures of nitric and nitrous acids and their oxoanions.

- With still more concentrated acid, N is reduced only to the +4 state in  $\text{NO}_2$ :

Nitrates form when  $\text{HNO}_3$  reacts with metals or with their hydroxides, oxides, or carbonates. *All nitrates are soluble in water.*

2. *Nitrous acid* ( $\text{HNO}_2$ ) is a much weaker acid that forms when metal nitrites are treated with a strong acid:

This acid forms the planar nitrite ion (Figure 14.17B) in which nitrogen's lone pair reduces the ideal  $120^\circ$  bond angle to  $115^\circ$ .

These two acids reveal a *general pattern in relative acid strength among oxoacids: the more O atoms bonded to the central nonmetal, the stronger the acid.* The O atoms pull electron density from the N atom, which in turn pulls electron density from the O of the O—H bond, facilitating the release of the  $\text{H}^+$  ion. The O atoms also stabilize the resulting oxoanion by delocalizing its negative charge. The same pattern occurs in the oxoacids of sulfur and the halogens; we'll discuss the pattern quantitatively in Chapter 18.

## Highlights of Phosphorus Chemistry

Like nitrogen, phosphorus forms important oxides (although not as many) and oxoacids. Here we focus on these compounds as well as on some other important phosphorus compounds.

**Phosphorus Oxides** Phosphorus forms two important oxides:

1. *Tetraphosphorus hexoxide* ( $\text{P}_4\text{O}_6$ ) has P in its +3 oxidation state. It forms when  $\text{P}_4$  reacts with limited oxygen:

$\text{P}_4\text{O}_6$  has the same tetrahedral orientation of the P atoms as in  $\text{P}_4$ , with an O atom between each pair of P atoms (Figure 14.18A).

2. *Tetraphosphorus decoxide* ( $\text{P}_4\text{O}_{10}$ ) has P in the +5 oxidation state. Commonly known as “phosphorus pentoxide” from the empirical formula ( $\text{P}_2\text{O}_5$ ), it forms when  $\text{P}_4$  burns in excess  $\text{O}_2$ :

Its structure is that of  $\text{P}_4\text{O}_6$  with another O atom bonded to each of the four corner P atoms (Figure 14.18B).  $\text{P}_4\text{O}_{10}$  is a powerful drying agent.

**Phosphorus Oxoacids and Oxoanions** The two common phosphorus oxoacids are phosphorous acid (note the different spelling) and phosphoric acid.

1. *Phosphorous acid* ( $\text{H}_3\text{PO}_3$ ) is formed when  $\text{P}_4\text{O}_6$  reacts with water:

The formula  $\text{H}_3\text{PO}_3$  is misleading because the acid has only two acidic H atoms; the third is bonded to the central P and does not dissociate. Phosphorous acid is a weak acid in water but reacts completely in two steps with excess strong base:

Salts of phosphorous acid contain the phosphite ion,  $\text{HPO}_3^{2-}$ .

2. *Phosphoric acid* ( $\text{H}_3\text{PO}_4$ ), one of the “top-10” most important compounds in manufacturing, is formed in a vigorous exothermic reaction of  $\text{P}_4\text{O}_{10}$  with water:

**Figure 14.18** Important oxides of phosphorus.

The presence of many H bonds makes pure  $\text{H}_3\text{PO}_4$  syrupy, more than 75 times as viscous as water. The laboratory-grade concentrated acid is an 85% by mass aqueous solution.  $\text{H}_3\text{PO}_4$  is a weak triprotic acid; in water, it loses one proton:

In excess strong base, however, the three protons dissociate completely in three steps to give the three phosphate oxoanions:

Phosphoric acid has a central role in fertilizer production and is also added to soft drinks for tartness. The various phosphate salts also have numerous essential applications.  $\text{Na}_3\text{PO}_4$  is a paint stripper and grease remover.  $\text{K}_3\text{PO}_4$  is used to stabilize latex for synthetic rubber, and  $\text{K}_2\text{HPO}_4$  is a radiator corrosion inhibitor. Ammonium phosphates are used as fertilizers and as flame retardants on curtains, and calcium phosphates are used in baking powders and toothpastes, as mineral supplements in livestock feed, and as fertilizers.

**Polyphosphates** When they are heated, hydrogen phosphates lose water and form P—O—P linkages in compounds called *polyphosphates*. A reaction in which an  $\text{H}_2\text{O}$  molecule is lost for every pair of groups that join is called a **dehydration-condensation**; this type of reaction occurs frequently in the formation of polyoxoanion chains and other polymeric structures, both synthetic and natural. For example, sodium diphosphate,  $\text{Na}_4\text{P}_2\text{O}_7$ , is prepared by heating sodium hydrogen phosphate:

The diphosphate ion,  $\text{P}_2\text{O}_7^{4-}$ , the smallest of the polyphosphates, consists of two  $\text{PO}_4$  units linked through a common oxygen corner (Figure 14.19A). Its reaction with water, the reverse of the previous reaction, generates heat:

A similar process is put to vital use by organisms, when a third  $\text{PO}_4$  unit linked to diphosphate creates the triphosphate grouping, part of the all-important high-energy biomolecule adenosine triphosphate (ATP). In Chapters 20 and 21, we discuss the central role of ATP in biological energy production. Extended polyphosphate chains consist of many tetrahedral  $\text{PO}_4$  units (Figure 14.19B) and are structurally similar to silicate chains.

**Phosphorus Compounds with Sulfur and Nitrogen** Phosphorus forms many sulfides and nitrides.  $\text{P}_4\text{S}_3$  is used in “strike anywhere” match heads, and  $\text{P}_4\text{S}_{10}$  is used in the manufacture of organophosphorus pesticides, such as malathion. Compounds of phosphorus and nitrogen called *polyphosphazenes* have properties similar to those of silicones. The  $-(\text{R}_2)\text{P}=\text{N}-$  unit is isoelectronic with the silicone unit,  $-(\text{R}_2)\text{Si}-\text{O}-$ . Sheets, films, fibers, and foams of polyphosphazene are water repellent, flame resistant, solvent resistant, and flexible at low temperatures—perfect for the gaskets and O-rings in spacecraft and polar vehicles.

**Figure 14.19** The diphosphate ion (A) and a polyphosphate chain (B).

## 14.8 GROUP 6A(16): THE OXYGEN FAMILY

The first two members of this group—gaseous nonmetallic oxygen (O) and solid nonmetallic sulfur (S)—are among the most important elements in industry, the environment, and living things. Two metalloids, selenium (Se) and tellurium (Te), appear next, followed by the radioactive metal polonium (Po), and finally livermorium (Lv), synthesized in 2000. The Group 6A(16) Family Portrait displays the features of these elements.

### How the Oxygen and Nitrogen Families Compare Physically

Group 6A(16) resembles Group 5A(15) in many respects, so let's look at some common themes. The pattern of physical properties we saw in 5A(15) appears again:

- *Oxygen*, like nitrogen, occurs as a low-boiling diatomic gas.
- *Sulfur*, like phosphorus, occurs as a polyatomic molecular solid.
- *Selenium*, like arsenic, commonly occurs as a gray metalloid.
- *Tellurium*, like antimony, is slightly more metallic but still displays network covalent bonding.
- *Polonium*, like bismuth, has a metallic crystal structure.

As in Group 5A(15), electrical conductivities increase steadily down Group 6A(16) as bonding changes from nonmetal molecules (insulators) to metalloid networks (semiconductors) to a metallic solid (conductor).

**Allotropism in the Oxygen Family** Allotropism is even more common in Group 6A(16) than in Group 5A(15).

1. *Oxygen*. Oxygen has two allotropes: life-giving dioxygen (O<sub>2</sub>), and poisonous triatomic ozone (O<sub>3</sub>). Dioxygen is colorless, odorless, paramagnetic, and thermally stable. In contrast, ozone is bluish, has a pungent odor, is diamagnetic, and decomposes in heat and especially in ultraviolet (UV) light:

This ability to absorb high-energy photons makes stratospheric ozone vital to life. A thinning of the ozone layer, observed above the North Pole and especially the South Pole, means that more UV light is reaching Earth's surface, with potentially hazardous effects. (We'll discuss the chemical causes of ozone depletion in Chapter 16.)

2. *Sulfur*. Sulfur is the allotrope “champion” of the periodic table, with more than 10 forms. The S atom's ability to bond to other S atoms (catenate) creates rings and chains, many with S—S bond lengths that range from 180 pm to 260 pm and bond angles ranging from 90° to 180°. The most stable allotrope is orthorhombic α-S<sub>8</sub>, which consists of a crown-shaped ring of eight atoms called *cyclo-S<sub>8</sub>* (Figure 14.20); all other S allotropes eventually revert to this one.

3. *Selenium*. Selenium also has several allotropes, some consisting of crown-shaped Se<sub>8</sub> molecules. Gray Se is composed of layers of helical chains. When molten glass, cadmium sulfide, and gray Se are mixed and heated in the absence of air, a ruby-red glass forms, which is still used in traffic lights. The ability of gray Se to

**Figure 14.20** The cyclo-S<sub>8</sub> molecule.

## KEY ATOMIC PROPERTIES, PHYSICAL PROPERTIES, AND REACTIONS

KEY	Atomic No.	Symbol	Atomic mass	Valence e <sup>-</sup> configuration (Common oxidation states)
8	O		16.00	2s <sup>2</sup> 2p <sup>4</sup> (-1, -2)
16	S		32.06	3s <sup>2</sup> 3p <sup>4</sup> (-2, +6, +4, +2)
34	Se		78.96	4s <sup>2</sup> 4p <sup>4</sup> (-2, +6, +4, +2)
52	Te		127.6	5s <sup>2</sup> 5p <sup>4</sup> (-2, +6, +4, +2)
84	Po		(209)	6s <sup>2</sup> 6p <sup>4</sup> (+4, +2)
116	Lv		(293)	7s <sup>2</sup> 7p <sup>4</sup>
				Observed in experiments at Dubna, Russia, in 2000

Atomic radius (pm)	Ionic radius (pm)
O 73	O <sup>2-</sup> 140
S 103	S <sup>2-</sup> 184
Se 119	Se <sup>2-</sup> 198
Te 142	
Po 168	Po <sup>4+</sup> 94

## Atomic Properties

Group electron configuration is  $ns^2np^4$ . As in Groups 3A(13) and 5A(15), a lower (+4) oxidation state becomes more common down the group. Down the group, atomic and ionic sizes increase, and IE and EN decrease.

## Physical Properties

Melting points increase through Te, which has covalent bonding, and then decrease for Po, which has metallic bonding. Densities of the elements as solids increase steadily.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

## Reactions

1. Halides are formed by direct combination:

2. The other elements in the group are oxidized by O<sub>2</sub>:

SO<sub>2</sub> is oxidized further, and the product is used in the final step of H<sub>2</sub>SO<sub>4</sub> manufacture (see text):

3. The thiosulfate ion is formed when an alkali metal sulfite reacts with sulfur, as in the preparation of "hypo" (photographers' developing solution):

conduct an electric current when illuminated is applied in photocopying. A film of amorphous Se is deposited on an aluminum drum and electrostatically charged. Exposure to a document produces an “image” of low and high positive charges corresponding to the document’s bright and dark areas. Negatively charged black, dry ink (toner) particles are attracted to the regions of high charge more than to those of low charge. This pattern of black particles is transferred electrostatically to paper, and the particles are fused to the paper’s surface by heat or solvent. Excess toner is removed from the Se film, the charges are “erased” by exposure to light, and the film is ready for the next page.

## How the Oxygen and Nitrogen Families Compare Chemically

Trends in Group 6A(16) chemical behavior are also similar to those in Group 5A(15). O and S occur as anions much more often than do N and P, but like N and P, they also bond covalently with almost every other nonmetal. Covalent bonds appear in the compounds of Se and Te (as in those of As and Sb), and Po behaves like a metal (as does Bi) in some saltlike compounds. In contrast to N, O has few common oxidation states, but the earlier pattern returns with the other Group 6A members: the +6, +4, and –2 states occur most often, with the lower positive (+4) state becoming more common in Te and Po [as the lower positive (+3) state does in Sb and Bi].

The range in atomic properties is wider in this group than in Group 5A(15) because of oxygen’s high EN (3.5) and great oxidizing strength, second only to that of fluorine. But the other members of Group 6A(16) behave very little like oxygen: they are much less electronegative, form anions much less often ( $S^{2-}$  occurs with active metals), and their hydrides exhibit no H bonding.

**Types and Properties of Hydrides** Oxygen forms two hydrides, water and hydrogen peroxide ( $H_2O_2$ ). Both have relatively high boiling points and viscosities due to H bonding. In peroxides, O is in the –1 oxidation state, midway between that in  $O_2$  (zero) and that in oxides (–2); thus,  $H_2O_2$  readily disproportionates:

Though its most familiar use is in hair bleach and disinfectants, much more  $H_2O_2$  is used to bleach paper, textiles, and leather and in sewage treatment to oxidize bacteria.

The other 6A(16) elements form foul-smelling, poisonous, gaseous hydrides ( $H_2E$ ) when the metal sulfide, selenide, and so forth is treated with acid. For example,

Hydrogen sulfide also forms naturally in swamps from the breakdown of organic matter. It is as toxic as HCN, and even worse, it anesthetizes your olfactory nerves, so that as its concentration increases, you smell it less! And the other hydrides are about 100 times *more* toxic.

In their bonding and thermal stability, these Group 6A(16) hydrides have several features in common with those of Group 5A(15):

- Only water and  $H_2O_2$  can form H bonds, so these substances melt and boil much higher than the other  $H_2E$  compounds (see Figure 12.15).
- Bond angles drop from the nearly tetrahedral  $104.5^\circ$  for  $H_2O$  to around  $90^\circ$  for the larger 6A(16) hydrides, suggesting that the central atom uses unhybridized  $p$  orbitals.
- E—H bond length increases, so bond energy decreases down the group. Thus,  $H_2Te$  decomposes above  $0^\circ C$ , and  $H_2Po$  can be made only in extreme cold because thermal energy from radioactive Po decomposes it. Another result of longer (weaker) bonds is that the 6A(16) hydrides are acids in water, and their acidity increases from  $H_2S$  to  $H_2Po$ .

**Types and Properties of Halides** Except for O, the Group 6A(16) elements form a wide range of halides, whose structure and reactivity patterns depend on the *sizes of the central atom and the surrounding halogens*:

- Sulfur forms many fluorides, a few chlorides, and one bromide, but no stable iodides.
- As the central atom becomes larger, the halides become more stable. Thus, tetrachlorides and tetrabromides of Se, Te, and Po are known, as are tetraiodides of Te and Po. Hexafluorides are known only for S, Se, and Te.

The inverse relationship between bond length and bond strength that we've seen previously does not account for this pattern. Rather, it is based on the effect of electron repulsions due to crowding of lone pairs and halogen (X) atoms around the central Group 6A(16) atom. With S, the larger X atoms would be too crowded, which explains why sulfur iodides do not occur. With increasing size of E, and therefore increasing length of E—X bonds, however, lone pairs and X atoms do not crowd each other as much, so a greater number of stable halides form.

## Highlights of Oxygen Chemistry: Range of Oxide Properties

Oxygen is the most abundant element on Earth's surface, occurring both as the free element and in innumerable oxides, silicates, carbonates, and phosphates, as well as in water. Virtually all free O<sub>2</sub> has been formed for billions of years by photosynthetic algae and multicellular plants in an overall equation that only looks simple:

The reverse process occurs during combustion and respiration. Through these O<sub>2</sub>-forming and O<sub>2</sub>-utilizing processes, the 1.5×10<sup>9</sup> km<sup>3</sup> of water on Earth is, on average, used and remade every 2 million years!

Every element (except He, Ne, and Ar) forms at least one oxide, many by direct combination. A spectrum of properties characterizes these compounds. Some oxides are gases that condense at very low temperatures, such as CO (bp = −192°C); others are solids that melt at extremely high temperatures, such as BeO (mp = 2530°C). Oxides cover the full range of conductivity: insulators (MgO), semiconductors (NiO), conductors (ReO<sub>3</sub>), and superconductors (YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub>). They may be thermally stable (CaO) or unstable (HgO), as well as chemically reactive (Li<sub>2</sub>O) or inert (Fe<sub>2</sub>O<sub>3</sub>).

Another useful way to classify element oxides is by their acid-base properties. The oxides of Group 6A(16) exhibit expected trends in acidity, with SO<sub>3</sub> [the higher (+6) oxide] the most acidic and PoO<sub>2</sub> [the lower (+4) oxide] the most basic.

## Highlights of Sulfur Chemistry

Like phosphorus, sulfur forms two common oxides and two oxoacids, one of which is essential to many industries. There are also several important metal sulfides.

**Sulfur Oxides** Sulfur forms two important oxides.

1. *Sulfur dioxide* (SO<sub>2</sub>) has S in its +4 oxidation state. It is a colorless, choking gas that forms when S, H<sub>2</sub>S, or a metal sulfide burns in air:

2. *Sulfur trioxide* (SO<sub>3</sub>), which has S in the +6 oxidation state, is produced when SO<sub>2</sub> reacts in O<sub>2</sub>. A catalyst (Chapter 16) must be used to speed up this very slow reaction. For the production of sulfuric acid, a vanadium(V) oxide catalyst is used:

**Sulfur Oxoacids** Sulfur forms two important oxoacids.

1. *Sulfurous acid* (H<sub>2</sub>SO<sub>3</sub>), formed when SO<sub>2</sub> dissolves in water, exists in equilibrium with hydrated SO<sub>2</sub> rather than as stable H<sub>2</sub>SO<sub>3</sub> molecules:

Sulfurous acid is weak and has two acidic protons, forming the hydrogen sulfite (bisulfite,  $\text{HSO}_3^-$ ) and sulfite ( $\text{SO}_3^{2-}$ ) ions with strong base. Because the S in  $\text{SO}_3^{2-}$  is in the +4 state and is easily oxidized to the +6 state, sulfites are good reducing agents and preserve foods and wine by eliminating undesirable products of air oxidation.

2. *Sulfuric acid* ( $\text{H}_2\text{SO}_4$ ) is produced when  $\text{SO}_2$  is oxidized catalytically to  $\text{SO}_3$ , which is then absorbed into concentrated  $\text{H}_2\text{SO}_4$  and treated with  $\text{H}_2\text{O}$ :

With more than 60 million tons produced each year in the United States alone,  $\text{H}_2\text{SO}_4$  ranks first among all industrial chemicals: it is vital to fertilizer production; metal, pigment, and textile processing; and soap and detergent manufacturing. (The production of  $\text{H}_2\text{SO}_4$  will be discussed in detail in Chapter 22.)

Concentrated laboratory-grade sulfuric acid is a viscous, colorless liquid that is 98%  $\text{H}_2\text{SO}_4$  by mass. Like other strong acids,  $\text{H}_2\text{SO}_4$  dissociates completely in water, forming the hydrogen sulfate (or bisulfate) ion, a much weaker acid:

Most common hydrogen sulfates and sulfates are water soluble, but those of the larger Group 2A(2) members ( $\text{Ca}^{2+}$ ,  $\text{Sr}^{2+}$ ,  $\text{Ba}^{2+}$ , and  $\text{Ra}^{2+}$ ),  $\text{Ag}^+$ , and  $\text{Pb}^{2+}$  are not.

Concentrated sulfuric acid is an excellent dehydrating agent. Its loosely held proton transfers to water in a highly exothermic formation of hydronium ( $\text{H}_3\text{O}^+$ ) ions. This process can occur even when the reacting substance contains no free water. For example,  $\text{H}_2\text{SO}_4$  dehydrates wood, natural fibers, and many other organic substances, such as table sugar ( $\text{CH}_2\text{O}$ )<sub>n</sub>, by removing the components of water from the molecular structure, leaving behind a carbonaceous mass (Figure 14.21).

**Figure 14.21** The dehydration of sugar by sulfuric acid.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

Sulfuric acid is one of the components of acid rain. Enormous amounts of  $\text{SO}_2$  are emitted by coal-burning power plants, petroleum refineries, and metal-ore smelters (see photo). In contact with  $\text{H}_2\text{O}$ , this  $\text{SO}_2$  and its oxidation product,  $\text{SO}_3$ , form  $\text{H}_2\text{SO}_3$  and  $\text{H}_2\text{SO}_4$  in the atmosphere, which then fall in rain, snow, and dust on animals, plants, buildings, and lakes (see Chemical Connections, Chapter 19).

**Metal Sulfides** Many metals combine directly with S to form *metal sulfides*. Sulfide ores are mined for the extraction of many metals, including copper, zinc, lead, and silver. Aside from the sulfides of Groups 1A(1) and 2A(2), most metal sulfides do not have discrete  $\text{S}^{2-}$  ions. Several transition metals, such as chromium, iron, and nickel, form covalent, alloy-like, nonstoichiometric compounds with S, such as  $\text{Cr}_{0.88}\text{S}$  and  $\text{Fe}_{0.86}\text{S}$ . Some important minerals contain  $\text{S}_2^{2-}$  ions; an example is iron pyrite, or “fool’s gold” ( $\text{FeS}_2$ ). We discuss the metallurgy of ores in Chapter 22.

**Industrial sources produce the sulfur oxides that lead to acid rain.**

## 14.9 GROUP 7A(17): THE HALOGENS

The halogens, the last elements of great reactivity, begin with fluorine (F), the strongest electron “grabber” of all. Chlorine (Cl, the most important halogen industrially), bromine (Br), and iodine (I) also form compounds with most elements, and even rare, radioactive astatine (At) is reactive; little is known of tennessine (Ts, first synthesized in 2010). The key features of this group are presented in the Group 7A(17) Family Portrait (*next page*).

### Physical Behavior of the Halogens

As expected from the increase in molar mass, the halogens display regular trends in their physical properties: melting and boiling points and heats of fusion and vaporization *increase* down Group 7A(17). The halogens exist as diatomic molecules that interact through dispersion forces, which *increase* in strength as the atoms become larger and, thus, more easily polarized. Even their color darkens with molar mass: F<sub>2</sub> is a very pale yellow gas, Cl<sub>2</sub> a yellow-green gas, Br<sub>2</sub> a brown-orange liquid, and I<sub>2</sub> a purple-black solid.

### Why the Halogens Are So Reactive

The Group 7A(17) elements react with most metals and nonmetals to form many ionic and covalent compounds: metal and nonmetal halides, halogen oxides, and oxoacids. The main reason for halogen reactivity is the same as for alkali metal reactivity—an electron configuration one electron away from that of a noble gas. Whereas a Group 1A(1) metal atom must lose one electron to attain a filled outer level, a Group 7A(17) nonmetal atom must gain one electron to fill its outer level. It accomplishes this filling in either of two ways:

1. Gaining an electron from a metal atom, thus forming a negative ion and an ionic bond with the positive metal ion.
2. Sharing an electron pair with a nonmetal atom, thus forming a covalent bond.

**Electronegativity and Bond Properties** The halogens display the largest range in electronegativity of any group, but all are electronegative enough to behave as nonmetals. Down the group, reactivity reflects the decrease in electronegativity: F<sub>2</sub> is the most reactive and I<sub>2</sub> the least. The exceptional reactivity of elemental F<sub>2</sub> is also related to the weakness of the F—F bond. Although bond energy generally decreases as atomic size increases down the group (Figure 14.22), F<sub>2</sub> deviates from this trend. The short F—F bond is weaker than expected because lone pairs on each small F atom repel those on the other. As a result of these factors, F<sub>2</sub> reacts with every element (except He, Ne, and Ar), in many cases, explosively.

**Figure 14.22** Bond energies and bond lengths of the halogens.

**Redox Behavior** The halogens act as *oxidizing agents* in the majority of their reactions, and halogens higher in the group can oxidize halide ions lower down:

Thus, the oxidizing ability of X<sub>2</sub> increases *up* the group: the higher the EN, the more strongly each X atom pulls electrons away. Similarly, the reducing ability of

## Atomic Properties

Group electron configuration is  $ns^2np^5$ ; elements lack one electron to complete their outer level. The -1 oxidation state is the most common for all members. Except for F, the halogens exhibit all odd-numbered states (+7 through -1). Down the group, atomic and ionic sizes increase steadily, as IE and EN decrease.

## Physical Properties

Down the group, melting and boiling points increase smoothly as a result of stronger dispersion forces between larger molecules. The densities of the elements as liquids (at the given temperatures) increase steadily with molar mass.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

## Reactions

1. The halogens ( $X_2$ ) oxidize many metals and nonmetals. The reaction with hydrogen, although not used commercially for HX production (except for high-purity HCl), is characteristic of these strong oxidizing agents:

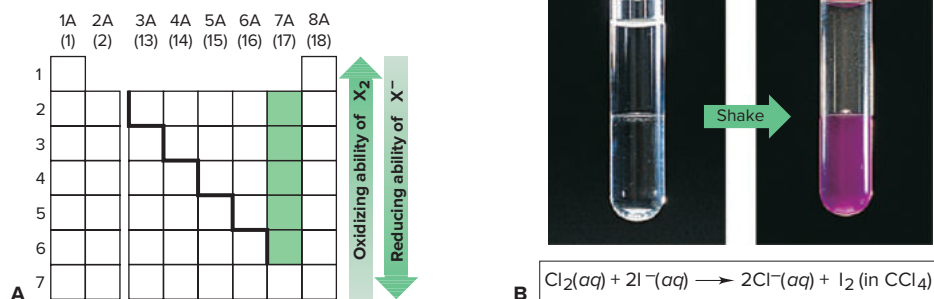

2. The halogens undergo disproportionation in water:

In aqueous base, the reaction goes to completion to form hypohalites and, at higher temperatures, halates, for example:

**Figure 14.23** The relative oxidizing ability of the halogens.

Source: B: © McGraw-Hill Education/ Stephen Frisch, photographer

$X^-$  increases *down* the group: the larger the ion, the more easily it gives up its electron (Figure 14.23A). Aqueous  $Cl_2$  added to a solution of  $I^-$  (Figure 14.23B, *top layer*) oxidizes the  $I^-$  to  $I_2$ , which dissolves in the  $CCl_4$  solvent (*bottom layer*) to give a purple solution.

The halogens undergo some important aqueous redox chemistry. Fluorine is such a powerful oxidizing agent that it reacts vigorously with water, oxidizing the O to produce  $O_2$ , some  $O_3$ , and HFO (hypofluorous acid). The other halogens undergo disproportionations (note the oxidation numbers):

At equilibrium, very little product is present unless excess  $OH^-$  ion is added, which reacts with the  $HX$  and  $HXO$  and drives the reaction to completion:

When  $X$  is  $Cl$ , the product mixture acts as a bleach: household bleach is a dilute solution of sodium hypochlorite ( $NaClO$ ). Heating causes  $XO^-$  to disproportionate further, creating oxoanions with  $X$  in a higher oxidation state:

## Highlights of Halogen Chemistry

Now, let's examine the compounds the halogens form with hydrogen and with each other, as well as their oxides, oxoanions, and oxoacids.

**The Hydrogen Halides** The halogens form gaseous hydrogen halides ( $HX$ ) through direct combination with  $H_2$  or through the action of a concentrated acid on the metal halide (a nonoxidizing acid is used for  $HBr$  and  $HI$ ):

Commercially, most  $HCl$  is formed as a byproduct in the chlorination of hydrocarbons for plastics production:

In this case, the vinyl chloride reacts in a separate process to form poly(vinyl chloride), or PVC, a polymer used extensively in pipes for plumbing and other purposes.

In water, gaseous  $HX$  molecules form a *hydrohalic acid*. Only  $HF$ , with its relatively short, strong bond, forms a weak acid:

$HF$  has many uses, including the synthesis of cryolite ( $Na_3AlF_6$ ) for aluminum production (Chapter 22), of fluorocarbons for refrigeration, and of  $NaF$  for water fluoridation.  $HF$  is also used in nuclear fuel processing and for glass etching.

The other hydrohalic acids are strong acids and dissociate completely to form the stoichiometric amount of  $\text{H}_3\text{O}^+$  ions:

(We saw reactions similar to these in Chapter 4. They involve *transfer* of a proton from acid to  $\text{H}_2\text{O}$  and are classified as *Brønsted-Lowry acid-base reactions*. In Chapter 18, we discuss them thoroughly and examine the relation between bond length and acidity of the larger  $\text{HX}$  molecules.)

$\text{HCl}$ , a common laboratory reagent, is used in the “pickling” of steel to remove adhering oxides and in the production of syrups, rayon, and plastic.  $\text{HCl}(aq)$  occurs naturally in the stomach fluids of mammals.

**Interhalogen Compounds: The “Halogen Halides”** Halogens react exothermically with one another to form many **interhalogen compounds**. The simplest are diatomic molecules, such as  $\text{ClF}$  and  $\text{BrCl}$ . Every binary combination of the four common halogens is known. The more electronegative halogen is in the  $-1$  oxidation state, and the less electronegative is in the  $+1$  state. Interhalogens of general formula  $\text{XY}_n$  ( $n = 3, 5, 7$ ) form through a variety of reactions, including direct reaction of the elements. In every case, the central atom has the lower *electronegativity* and a positive oxidation state.

Some interhalogens are used commercially as powerful *fluorinating agents*, which react with metals, nonmetals, and oxides—even wood and asbestos:

Their reactions with water are nearly explosive and yield  $\text{HF}$  and the *oxoacid with the central halogen in the same oxidation state*, for example:

**The Oddness and Evenness of Oxidation States** *Almost all stable molecules have paired electrons, either as bonding or lone pairs. Therefore, when bonds form or break, two electrons are involved, so the oxidation state changes by 2.* For this reason, odd-numbered groups exhibit odd-numbered oxidation states and even-numbered groups exhibit even-numbered states.

1. *Odd-numbered oxidation states.* Consider the interhalogens. Four general formulas are  $\text{XY}$ ,  $\text{XY}_3$ ,  $\text{XY}_5$ , and  $\text{XY}_7$ ; examples are shown in Figure 14.24. With  $\text{Y}$  in the  $-1$  state,  $\text{X}$  must be in the  $+1$ ,  $+3$ ,  $+5$ , or  $+7$  state, respectively. The  $-1$  state arises when  $\text{Y}$  fills its valence level; the  $+7$  state arises when the central halogen ( $\text{X}$ ) is completely oxidized, that is, when all seven valence electrons have shifted away from it to the more electronegative  $\text{Y}$  atoms around it.

Let’s examine the iodine fluorides to see why the oxidation states jump by two units. When  $\text{I}_2$  reacts with  $\text{F}_2$ ,  $\text{IF}$  forms (note the oxidation number of  $\text{I}$ ):

**Figure 14.24** Molecular shapes of the main types of interhalogen compounds.

In  $\text{IF}_3$ , I uses *two* more valence electrons to form *two* more bonds:

Otherwise, an unstable lone-electron species containing two fluorines would form. When  $\text{IF}_3$  reacts with more fluorine, another jump of two units occurs and the pentafluoride forms:

With still more fluorine, the heptafluoride forms:

2. *Even-numbered oxidation states.* An element in an even-numbered group, such as sulfur in Group 6A(16), shows the same tendency to have paired electrons in its compounds. Elemental sulfur (oxidation number, O.N. = 0) gains or shares two electrons to complete its shell (O.N. = -2). It uses two electrons to react with fluorine, for example, to form  $\text{SF}_2$  (O.N. = +2), two more electrons to form  $\text{SF}_4$  (O.N. = +4), and two more to form  $\text{SF}_6$  (O.N. = +6).

Thus, an element with one even state typically has all even states, and an element with one odd state typically has all odd states. To reiterate the main point, *successive oxidation states differ by two units because stable molecules have electrons in pairs around their atoms.*

**Halogen Oxides, Oxoacids, and Oxoanions** The Group 7A(17) elements form many oxides that are *powerful oxidizing agents and acids in water*. Dichlorine monoxide ( $\text{Cl}_2\text{O}$ ) and especially chlorine dioxide ( $\text{ClO}_2$ ) are used to bleach paper (Figure 14.25).  $\text{ClO}_2$  is unstable to heat and shock, so it is prepared on site, and more than 100,000 tons are used annually:

The dioxide has an unpaired electron and Cl in the unusual +4 oxidation state.

Chlorine is in its highest (+7) oxidation state in dichlorine heptoxide,  $\text{Cl}_2\text{O}_7$ , which is a symmetrical molecule formed when two  $\text{HClO}_4$  ( $\text{HO}-\text{ClO}_3$ ) molecules undergo a dehydration-condensation reaction:

The halogen oxoacids and oxoanions are produced by reaction of the halogens and their oxides with water. Most of the oxoacids are stable only in solution. Table 14.4 (*on the next page*) shows ball-and-stick models of the acids in which each atom has its lowest formal charge; note the formulas, which emphasize that the H is bonded to O. The hypohalites ( $\text{XO}^-$ ), halites ( $\text{XO}_2^-$ ), and halates ( $\text{XO}_3^-$ ) are oxidizing agents formed by aqueous disproportionation reactions [see the Group 7A(17) Family Portrait, reaction 2]. You may have heated solid alkali chlorates in the laboratory to form small amounts of  $\text{O}_2$ :

Potassium chlorate is the oxidizer in “safety” matches.

Several perchalates ( $\text{XO}_4^-$ ) are also strong oxidizing agents. Thousands of tons of perchlorates are made each year for use in explosives and fireworks. Ammonium

**Figure 14.25** Chlorine oxides. Structures show each central Cl atom with its lowest formal charge.

Table 14.4

The Known Halogen Oxoacids\*

Central Atom	Hypohalous Acid (HOX)	Halous Acid (HOXO)	Halic Acid (HOXO <sub>2</sub> )	Perhalic Acid (HOXO <sub>3</sub> )
				
Fluorine	HOF	—	—	—
Chlorine	HOCl	HOClO	HOClO <sub>2</sub>	HOClO <sub>3</sub>
Bromine	HOBr	HOBrO	HOBrO <sub>2</sub>	HOBrO <sub>3</sub>
Iodine	HOI	—	HOIO <sub>2</sub>	HOIO <sub>3</sub> , (HO) <sub>5</sub> IO
Oxoanion	Hypohalite	Halite	Halate	Perhalate

\*Lone pairs are shown only on the halogen atom, and each atom has its lowest formal charge.

perchlorate, prepared from sodium perchlorate, was the oxidizing agent for the aluminum powder in the solid-fuel booster rockets of space shuttles; each launch used more than 700 tons of NH<sub>4</sub>ClO<sub>4</sub>:

The relative strengths of the halogen oxoacids depend on two factors:

1. *Electronegativity of the halogen.* Among oxoacids with the halogen in the same oxidation state, such as the halic acids, HXO<sub>3</sub> (or HOXO<sub>2</sub>), acid strength decreases as the halogen's EN decreases:

The more electronegative the halogen, the more electron density it removes from the O—H bond, and the more easily the proton is lost.

2. *Oxidation state of the halogen.* Among oxoacids of a given halogen, such as chlorine, acid strength decreases as the oxidation state of the halogen decreases:

The higher the oxidation state (number of attached O atoms) of the halogen, the more electron density it pulls from the O—H bond. We consider these trends quantitatively in Chapter 18.

## 14.10 GROUP 8A(18): THE NOBLE GASES

The last main group consists of individual atoms too “noble” to interact much with others. The Group 8A(18) elements display regular trends in physical properties and very low, if any, reactivity. The group consists of the following elements: helium (He), the second most abundant element in the universe; neon (Ne); argon (Ar); krypton (Kr), xenon (Xe), and radioactive radon (Rn), the only members for which compounds have been well studied; and the very rare oganesson (Og), a few atoms of which were synthesized in 2002 and 2005. The noble gases make up about 1% by volume of the atmosphere, primarily due to the abundance of Ar. The Group 8A(18) Family Portrait presents an overview of these elements.

### How the Noble Gases and Alkali Metals Contrast Physically

Lying at the far right side of the periodic table, the Group 8A(18) elements come as close to behaving as ideal gases as any other substances. Like the alkali metals

KEY ATOMIC AND PHYSICAL PROPERTIES

KEY	Atomic No.	Symbol	Atomic mass	Valence e <sup>-</sup> configuration (Common oxidation states)	
2	He	4.003	1s <sup>2</sup>	(none)	
10	Ne	20.18	2s <sup>2</sup> 2p <sup>6</sup>	(none)	
18	Ar	39.95	3s <sup>2</sup> 3p <sup>6</sup>	(none)	
36	Kr	83.80	4s <sup>2</sup> 4p <sup>6</sup>	(+2)	
54	Xe	131.3	5s <sup>2</sup> 5p <sup>6</sup>	(+8, +6, +4, +2)	
86	Rn	(222)	6s <sup>2</sup> 6p <sup>6</sup>	(+2)	Mass spectral peak
118	Og	(294)	7s <sup>2</sup> 7p <sup>6</sup>		Observed in experiments at Dubna, Russia, in 2002 and 2005

Atomic radius (pm)
He 31
Ne 71
Ar 98
Kr 112
Xe 131
Rn (140)

Atomic Properties

Group electron configuration is 1s<sup>2</sup> for He and ns<sup>2</sup>np<sup>6</sup> for the others. The valence shell is filled. Only Kr, Xe, and Rn are known to form compounds. The more reactive Xe exhibits all even oxidation states (+2 to +8). This group contains the smallest atoms with the highest IEs in their periods. Down the group, atomic size increases and IE decreases steadily. (EN values are given only for Kr and Xe.)

Physical Properties

Melting and boiling points of these gaseous elements are extremely low but increase down the group because of stronger dispersion forces. Note the extremely small liquid ranges. Densities (at STP) increase steadily, as expected.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

at the other end of the periodic table, the noble gases display regular trends in physical properties. However, whereas melting and boiling points and heats of fusion and vaporization *decrease* down Group 1A(1), these properties *increase* down Group 8A(18). The reason for these opposite trends is the different bonding interactions in the elements. The alkali metals consist of atoms held together by metallic bonding, which *decreases* in strength as the atoms become larger. The noble gases, on the other hand, exist as individual atoms that interact through dispersion forces, which *increase* in strength as the atoms become larger and more easily polarized. Nevertheless, these dispersion forces are so weak that only at very low temperatures do the elements condense and solidify. For example, even argon, which makes up almost 1% of the atmosphere, melts at  $-189^{\circ}\text{C}$  and boils only about three degrees higher.

### How Noble Gases Can Form Compounds

Following their discovery in the late 19<sup>th</sup> century, these elements were considered, and even formerly named, the “inert” gases. Early 20<sup>th</sup>-century atomic theory and, more important, all experiments supported this idea. Then, in 1962, all this changed when the first noble gas compound was prepared. How, with filled outer levels and extremely high ionization energies, *can* noble gases react?

The discovery of noble gas reactivity is a classic example of clear thinking in the face of an unexpected event. A young inorganic chemist named Neil Bartlett was studying platinum fluorides, known to be strong oxidizing agents. When he accidentally exposed  $\text{PtF}_6$  to air, its deep-red color lightened slightly, and analysis showed that the  $\text{PtF}_6$  had oxidized  $\text{O}_2$  to form the ionic compound  $[\text{O}_2]^+[\text{PtF}_6]^-$ . Knowing that the ionization energy of the oxygen molecule ( $\text{O}_2 \rightarrow \text{O}_2^+ + e^-$ ;  $\text{IE} = 1175 \text{ kJ/mol}$ ) is very close to  $\text{IE}_1$  of xenon (1170 kJ/mol), Bartlett reasoned that  $\text{PtF}_6$  might be able to oxidize xenon. Shortly thereafter, he prepared  $\text{XePtF}_6$ , an orange-yellow solid. Within a few months, the white crystalline  $\text{XeF}_2$  and  $\text{XeF}_4$  (Figure 14.26) were also prepared. In addition to its +2 and +4 oxidation states, Xe has the +6 state in several compounds, such as  $\text{XeF}_6$ , and the +8 state in the unstable oxide,  $\text{XeO}_4$ . A few compounds of Kr and Rn have also been made.

## CHAPTER REVIEW GUIDE

### Learning Objectives

Relevant section (§) numbers appear in parentheses.

#### Understand These Concepts

*Note: Many characteristic reactions appear in the “Reactions” section of each group’s Family Portrait.*

- How hydrogen is similar to, yet different from, alkali metals and halogens; the differences between ionic, covalent, and metallic hydrides (§14.1)
- Key horizontal trends in atomic properties, types of bonding, oxide acid-base properties, and redox behavior as the elements change from metals to nonmetals (§14.2)
- How small atomic size and limited number of valence orbitals account for the anomalous behavior of the Period 2 member of each group (§14.2)
- How the  $ns^1$  configuration accounts for the physical and chemical properties of the alkali metals (§14.3)
- How the  $ns^2$  configuration accounts for the key differences between Groups 1A(1) and 2A(2) (§14.4)
- The basis of the three important diagonal relationships (Li/Mg, Be/Al, B/Si) (§14.4–14.6)
- How the presence of inner  $(n - 1)d$  electrons affects properties in Group 3A(13) (§14.5)
- Patterns among larger members of Groups 3A(13) to 6A(16): two common oxidation states (inert-pair effect), lower state more important going down the group, and more basic oxide with the element in the lower state (§14.5–14.8)
- How boron attains an octet of electrons (§14.5)
- The effect of bonding on the physical behavior of Groups 4A(14) to 6A(16) (§14.6–14.8)
- Allotropism in carbon, phosphorus, and sulfur (§14.6–14.8)
- How atomic properties lead to catenation and multiple bonds in organic compounds (§14.6)
- Structures and properties of the silicates and silicones (§14.6)
- Patterns of behavior among hydrides and halides of Groups 5A(15) and 6A(16) (§14.7, §14.8)
- The meaning of disproportionation (§14.7)

- Structure and chemistry of the nitrogen oxides and oxoacids (§14.7)
- Structure and chemistry of the phosphorus oxides and oxoacids (§14.7)
- Dehydration-condensation reactions and polyphosphate structures (§14.7)
- Structure and chemistry of the sulfur oxides and oxoacids (§14.8)
- How the  $ns^2np^5$  configuration accounts for halogen reactivity with metals (§14.9)
- Why the oxidation states of an element change by two units (§14.9)
- Structure and chemistry of the halogen oxides and oxoacids (§14.9)
- How the  $ns^2np^6$  configuration accounts for the relative inertness of the noble gases (§14.10)

## Key Terms

Page numbers appear in parentheses.

allotrope (600)	disproportionation reaction (609)	interhalogen compound (620)	silicone (603)
bridge bond (598)	dehydration-condensation reaction (611)	silicate (603)	
diagonal relationship (595)			

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

### Hydrogen, the Simplest Atom

#### Concept Review Questions

- 14.1** Hydrogen has only one proton, but its  $IE_1$  is much greater than that of lithium, which has three protons. Explain.
- 14.2** Sketch a periodic table, and label the areas containing elements that give rise to the three types of hydrides.

#### Skill-Building Exercises (grouped in similar pairs)

- 14.3** Draw Lewis structures for the following compounds, and predict which member of each pair will form H bonds:
- (a)  $NF_3$  or  $NH_3$                       (b)  $CH_3OCH_3$  or  $CH_3CH_2OH$
- 14.4** Draw Lewis structures for the following compounds, and predict which member of each pair will form H bonds:
- (a)  $NH_3$  or  $AsH_3$                       (b)  $CH_4$  or  $H_2O$

**14.5** Complete and balance the following equations:

- (a) An active metal reacting with acid,  
 $Al(s) + HCl(aq) \longrightarrow$
- (b) A saltlike (alkali metal) hydride reacting with water,  
 $LiH(s) + H_2O(l) \longrightarrow$

**14.6** Complete and balance the following equations:

- (a) A saltlike (alkaline earth metal) hydride reacting with water,  
 $CaH_2(s) + H_2O(l) \longrightarrow$
- (b) Reduction of a metal halide by hydrogen to form a metal,  
 $PdCl_2(aq) + H_2(g) \longrightarrow$

#### Problems in Context

- 14.7** Compounds such as  $NaBH_4$ ,  $Al(BH_4)_3$ , and  $LiAlH_4$  are complex hydrides used as reducing agents in many syntheses.
- (a) Give the oxidation state of each element in these compounds.

- (b) Write a Lewis structure for the polyatomic anion in  $NaBH_4$ , and predict its shape.

**14.8** Unlike the  $F^-$  ion, which has an ionic radius close to 133 pm in all alkali metal fluorides, the ionic radius of  $H^-$  varies from 137 pm in  $LiH$  to 152 pm in  $CsH$ . Suggest an explanation for the large variability in the size of  $H^-$  but not  $F^-$ .

### Trends Across the Periodic Table: The Period 2 Elements

#### Concept Review Questions

- 14.9** How does the maximum oxidation number vary across a period in the main groups? Is the pattern in Period 2 different?
- 14.10** What correlation, if any, exists for the Period 2 elements between group number and the number of covalent bonds the element typically forms? How is the correlation different for elements in Periods 3 to 6?
- 14.11** Each of the chemically active Period 2 elements forms stable compounds in which it has bonds to fluorine.
- (a) What are the names and formulas of these compounds?
- (b) Does  $\Delta EN$  increase or decrease left to right across the period?
- (c) Does percent ionic character increase or decrease left to right?
- (d) Draw Lewis structures for these compounds.
- 14.12** Period 6 contains the first series of inner transition elements.
- (a) How many elements belong to Period 6? How many metals?
- (b) It contains no metalloids. Where is the metal/nonmetal boundary in Period 6?
- 14.13** An element forms an oxide,  $E_2O_3$ , and a fluoride,  $EF_3$ .
- (a) Of which two groups might E be a member?
- (b) How does the group to which E belongs affect the properties of the oxide and the fluoride?

**14.14** Fluorine lies between oxygen and neon in Period 2. Whereas atomic sizes and ionization energies of these three elements change smoothly, their electronegativities display a dramatic change. What is this change, and how do their electron configurations explain it?

**Group 1A(1): The Alkali Metals****Concept Review Questions**

**14.15** Lithium salts are often much less soluble in water than the corresponding salts of other alkali metals. For example, at 18°C, the concentration of a saturated LiF solution is  $1.0 \times 10^{-2} M$ , whereas that of a saturated KF solution is 1.6 M. How can you explain this behavior?

**14.16** The alkali metals play virtually the same general chemical role in all their reactions.

- (a) What is this role?  
 (b) How is it based on atomic properties?  
 (c) Using sodium, write two balanced equations that illustrate this role.

**14.17** How do atomic properties account for the low densities of the Group 1A(1) elements?

**Skill-Building Exercises (grouped in similar pairs)**

**14.18** Each of the following properties shows a regular trend in Group 1A(1). Predict whether each increases or decreases *down* the group:

- (a) Density (b) Ionic size (c) E—E bond energy  
 (d)  $IE_1$  (e) Magnitude of  $\Delta H_{\text{hydr}}$  of  $E^+$  ion

**14.19** Each of the following properties shows a regular trend in Group 1A(1). Predict whether each increases or decreases *up* the group:

- (a) Melting point (b) E—E bond length (c) Hardness  
 (d) Molar volume (e) Lattice energy of EBr

**14.20** Write a balanced equation for the formation from its elements of sodium peroxide, an industrial bleach.

**14.21** Write a balanced equation for the formation of rubidium bromide through reaction of a strong acid and a strong base.

**Problems in Context**

**14.22** Although the alkali metal halides can be prepared directly from the elements, the far less expensive industrial route is treatment of the carbonate or hydroxide with aqueous hydrohalic acid (HX) followed by recrystallization. Balance the reaction between potassium carbonate and aqueous hydroiodic acid.

**14.23** Lithium forms several useful organolithium compounds. Calculate the mass percent of Li in the following:

- (a) Lithium stearate ( $C_{17}H_{35}COOLi$ ), a water-resistant grease used in cars because it does not harden at cold temperatures  
 (b) Butyllithium ( $LiC_4H_9$ ), a reagent in organic syntheses

**Group 2A(2): The Alkaline Earth Metals****Concept Review Questions**

**14.24** How do Groups 1A(1) and 2A(2) compare with respect to reaction of the metals with water?

**14.25** Alkaline earth metals are involved in two key diagonal relationships in the periodic table.

- (a) Give the two pairs of elements in these diagonal relationships.  
 (b) For each pair, cite two similarities that demonstrate the relationship.  
 (c) Why are the members of each pair so similar in behavior?

**14.26** The melting points of alkaline earth metals are many times higher than those of the alkali metals. Explain this difference on the basis of atomic properties. Name three other physical properties for which Group 2A(2) metals have higher values than the corresponding 1A(1) metals.

**Skill-Building Exercises (grouped in similar pairs)**

**14.27** Write a balanced equation for each reaction:

- (a) “Slaking” of lime (treatment with water)  
 (b) Combustion of calcium in air

**14.28** Write a balanced equation for each reaction:

- (a) Thermal decomposition of witherite (barium carbonate)  
 (b) Neutralization of stomach acid (HCl) by milk of magnesia (magnesium hydroxide)

**Problems in Context**

**14.29** Lime (CaO) is one of the most abundantly produced chemicals in the world. Write balanced equations for these reactions:

- (a) The preparation of lime from natural sources  
 (b) The use of slaked lime to remove  $SO_2$  from flue gases  
 (c) The reaction of lime with arsenic acid ( $H_3AsO_4$ ) to manufacture the insecticide calcium arsenate  
 (d) The regeneration of NaOH in the paper industry by reaction of lime with aqueous sodium carbonate

**14.30** In some reactions, Be behaves like a typical alkaline earth metal; in others, it does not. Complete and balance the following:

- (a)  $BeO(s) + H_2O(l) \longrightarrow$   
 (b)  $BeCl_2(l) + Cl^-(l; \text{from molten NaCl}) \longrightarrow$

In which reaction does Be behave like the other Group 2A(2) members?

**Group 3A(13): The Boron Family****Concept Review Questions**

**14.31** How do the transition metals in Period 4 affect the pattern of ionization energies in Group 3A(13)? How does this pattern compare with that in Group 3B(3)?

**14.32** How do the acidities of aqueous solutions of  $Tl_2O$  and  $Tl_2O_3$  compare with each other? Explain.

**14.33** Despite the expected decrease in atomic size, there is an unexpected drop in the first ionization energy between Groups 2A(2) and 3A(13) in Periods 2 through 4. Explain this pattern in terms of electron configurations and orbital energies.

**14.34** Many compounds of Group 3A(13) elements have chemical behavior that reflects an electron deficiency.

- (a) What is the meaning of *electron deficiency*?  
 (b) Give two reactions that illustrate this behavior.

**14.35** Boron’s chemistry is not typical of its group.

- (a) Cite three ways in which boron and its compounds differ significantly from the other 3A(13) members and their compounds.  
 (b) What is the reason for these differences?

**Skill-Building Exercises (grouped in similar pairs)**

**14.36** Rank the following oxides in order of increasing *acidity* of their aqueous solutions:  $Ga_2O_3$ ,  $Al_2O_3$ ,  $In_2O_3$ .

**14.37** Rank the following hydroxides in order of increasing *basicity* of their aqueous solutions:  $Al(OH)_3$ ,  $B(OH)_3$ ,  $In(OH)_3$ .

**14.38** Thallium forms the compound  $TlI_3$ . What is the apparent oxidation state of Tl in this compound? Given that the anion is  $I_3^-$ , what is the actual oxidation state of Tl? Draw the shape of the anion, giving its VSEPR class and bond angles. Propose a reason why the compound does not exist as  $(Tl^{3+})(I_3^-)$ .

**14.39** Very stable dihalides of the Group 3A(13) metals are known. What is the apparent oxidation state of Ga in  $\text{GaCl}_2$ ? Given that  $\text{GaCl}_2$  consists of a  $\text{Ga}^+$  cation and a  $\text{GaCl}_4^-$  anion, what are the actual oxidation states of Ga? Draw the shape of the anion, giving its VSEPR class and bond angles.

### Problems in Context

**14.40** Give the name and symbol or formula of a Group 3A(13) element or compound that fits each description or use:

- Component of heat-resistant (Pyrex-type) glass
- Largest temperature range for liquid state of an element
- Elemental substance with three-center, two-electron bonds
- Metal protected from oxidation by adherent oxide coat
- Toxic metal that lies between two other toxic metals

**14.41** Indium (In) reacts with HCl to form a diamagnetic solid with the formula  $\text{InCl}_2$ .

- Write condensed electron configurations for In,  $\text{In}^+$ ,  $\text{In}^{2+}$ , and  $\text{In}^{3+}$ .
- Which of these species is (are) diamagnetic and which paramagnetic?
- What is the apparent oxidation state of In in  $\text{InCl}_2$ ?
- Given your answers to parts (b) and (c), explain how  $\text{InCl}_2$  can be diamagnetic.

**14.42** Use VSEPR theory to draw structures, with ideal bond angles, for boric acid and the anion it forms when it reacts with water.

**14.43** Boron nitride (BN) has a structure similar to graphite, but is a white insulator rather than a black conductor. It is synthesized by heating diboron trioxide with ammonia at about  $1000^\circ\text{C}$ .

- Write a balanced equation for the formation of BN; water also forms.
- Calculate  $\Delta H_{\text{rxn}}^\circ$  for the production of BN ( $\Delta H_f^\circ$  of BN is  $-254 \text{ kJ/mol}$ ).
- Boron is obtained from the mineral borax,  $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$ . How much borax is needed to produce 1.0 kg of BN, assuming 72% yield?

### Group 4A(14): The Carbon Family

#### Concept Review Questions

**14.44** How does the basicity of  $\text{SnO}_2$  in water compare with that of  $\text{CO}_2$ ? Explain.

**14.45** Nearly every compound of silicon has the element in the +4 oxidation state. In contrast, most compounds of lead have the element in the +2 state.

- What general observation do these facts illustrate?
- Explain in terms of atomic and molecular properties.
- Give an analogous example from Group 3A(13).

**14.46** The sum of  $\text{IE}_1$  through  $\text{IE}_4$  for Group 4A(14) elements shows a decrease from C to Si, a slight increase from Si to Ge, a decrease from Ge to Sn, and an increase from Sn to Pb.

- What is the expected trend for IEs down a group?
- Suggest a reason for the deviations in Group 4A(14).
- Which group might show even greater deviations?

**14.47** Give explanations for the large drops in melting point from C to Si and from Ge to Sn.

**14.48** What is an allotrope? Name two Group 4A(14) elements that exhibit allotropism, and identify two of their allotropes.

**14.49** Even though EN values vary relatively little down Group 4A(14), the elements change from nonmetal to metal. Explain.

**14.50** How do atomic properties account for the enormous number of carbon compounds? Why don't other Group 4A(14) elements behave similarly?

### Skill-Building Exercises (grouped in similar pairs)

**14.51** Draw a Lewis structure for each species:

- The cyclic silicate ion  $\text{Si}_4\text{O}_{12}^{8-}$
- A cyclic hydrocarbon with formula  $\text{C}_4\text{H}_8$

**14.52** Draw a Lewis structure for each species:

- The cyclic silicate ion  $\text{Si}_6\text{O}_{18}^{12-}$
- A cyclic hydrocarbon with formula  $\text{C}_6\text{H}_{12}$

### Problems in Context

**14.53** Zeolite A,  $\text{Na}_{12}[(\text{AlO}_2)_{12}(\text{SiO}_2)_{12}] \cdot 27\text{H}_2\text{O}$ , is used to soften water because it replaces  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  dissolved in the water with  $\text{Na}^+$ . Hard water from a certain source is  $4.5 \times 10^{-3} \text{ M}$   $\text{Ca}^{2+}$  and  $9.2 \times 10^{-4} \text{ M}$   $\text{Mg}^{2+}$ , and a pipe delivers 25,000 L of this hard water per day. What mass (in kg) of zeolite A is needed to soften a week's supply of the water? (Assume zeolite A loses its capacity to exchange ions when 85 mol % of its  $\text{Na}^+$  has been lost.)

**14.54** Give the name and symbol or formula of a Group 4A(14) element or compound that fits each description or use:

- Hardest known natural substance
- Medicinal antacid
- Atmospheric gas implicated in the greenhouse effect
- Gas that binds to Fe(II) in blood
- Element used in the manufacture of computer chips

**14.55** One similarity between B and Si is the explosive combustion of their hydrides in air. Write balanced equations for the combustion of  $\text{B}_2\text{H}_6$  and of  $\text{Si}_4\text{H}_{10}$ .

### Group 5A(15): The Nitrogen Family

#### Concept Review Questions

**14.56** Which Group 5A(15) elements form trihalides? Pentahalides? Explain.

**14.57** As you move down Group 5A(15), the melting points of the elements increase and then decrease. Explain.

**14.58** (a) What is the range of oxidation states shown by the elements of Group 5A(15) as you move down the group?

(b) How does this range illustrate the general rule for the range of oxidation states in groups on the right side of the periodic table?

**14.59** Bismuth(V) compounds are such powerful oxidizing agents that they have not been prepared in pure form. How is this fact consistent with the location of Bi in the periodic table?

**14.60** Rank the following oxides in order of increasing acidity in water:  $\text{Sb}_2\text{O}_3$ ,  $\text{Bi}_2\text{O}_3$ ,  $\text{P}_4\text{O}_{10}$ ,  $\text{Sb}_2\text{O}_5$ .

### Skill-Building Exercises (grouped in similar pairs)

**14.61** Assuming acid strength relates directly to electronegativity of the central atom, rank  $\text{H}_3\text{PO}_4$ ,  $\text{HNO}_3$ , and  $\text{H}_3\text{AsO}_4$  in order of increasing acid strength.

**14.62** Assuming acid strength relates directly to number of O atoms bonded to the central atom, rank  $\text{H}_2\text{N}_2\text{O}_2$  [or  $(\text{HON})_2$ ],  $\text{HNO}_3$  (or  $\text{HONO}_2$ ), and  $\text{HNO}_2$  (or  $\text{HONO}$ ) in order of decreasing acid strength.

**14.63** Complete and balance the following:

- (a)  $\text{As}(s) + \text{excess O}_2(g) \longrightarrow$   
 (b)  $\text{Bi}(s) + \text{excess F}_2(g) \longrightarrow$   
 (c)  $\text{Ca}_3\text{As}_2(s) + \text{H}_2\text{O}(l) \longrightarrow$

**14.64** Complete and balance the following:

- (a)  $\text{Excess Sb}(s) + \text{Br}_2(l) \longrightarrow$   
 (b)  $\text{HNO}_3(aq) + \text{MgCO}_3(s) \longrightarrow$   
 (c)  $\text{K}_2\text{HPO}_4(s) \xrightarrow{\Delta}$

**14.65** Complete and balance the following:

- (a)  $\text{N}_2(g) + \text{Al}(s) \xrightarrow{\Delta}$  (b)  $\text{PF}_5(g) + \text{H}_2\text{O}(l) \longrightarrow$

**14.66** Complete and balance the following:

- (a)  $\text{AsCl}_3(l) + \text{H}_2\text{O}(l) \longrightarrow$  (b)  $\text{Sb}_2\text{O}_3(s) + \text{NaOH}(aq) \longrightarrow$

**14.67** Based on the relative sizes of F and Cl, predict the structure of  $\text{PF}_2\text{Cl}_3$ .

**14.68** Use the VSEPR model to predict the structure of the cyclic ion  $\text{P}_3\text{O}_3^{3-}$ .

### Problems in Context

**14.69** The pentafluorides of the larger members of Group 5A(15) have been prepared, but N can have only eight electrons. A claim has been made that, at low temperatures, a compound with the empirical formula  $\text{NF}_5$  forms. Draw a possible Lewis structure for this compound. (*Hint*:  $\text{NF}_5$  is ionic.)

**14.70** Give the name and symbol or formula of a Group 5A(15) element or compound that fits each description or use:

- (a) Hydride that exhibits hydrogen bonding  
 (b) Compound used in “strike-anywhere” match heads  
 (c) Oxide used as a laboratory drying agent  
 (d) Molecule with an odd-electron atom (two examples)  
 (e) Compound used as an additive in soft drinks

**14.71** In addition to those in Table 14.3, other less stable nitrogen oxides exist. Draw a Lewis structure for each of the following:

- (a)  $\text{N}_2\text{O}_2$ , a dimer of nitrogen monoxide with an N—N bond  
 (b)  $\text{N}_2\text{O}_2$ , a dimer of nitrogen monoxide with no N—N bond  
 (c)  $\text{N}_2\text{O}_3$  with no N—N bond  
 (d)  $\text{NO}^+$  and  $\text{NO}_3^-$ , products of the ionization of liquid  $\text{N}_2\text{O}_4$

**14.72** Nitrous oxide ( $\text{N}_2\text{O}$ ), the “laughing gas” used as an anesthetic by dentists, is made by thermal decomposition of solid  $\text{NH}_4\text{NO}_3$ . Write a balanced equation for this reaction. What are the oxidation states of N in  $\text{NH}_4\text{NO}_3$  and in  $\text{N}_2\text{O}$ ?

**14.73** Write balanced equations for the thermal decomposition of potassium nitrate ( $\text{O}_2$  is also formed in both cases):

- (a) At low temperature to the nitrite  
 (b) At high temperature to the metal oxide and nitrogen

### Group 6A(16): The Oxygen Family

#### Concept Review Questions

**14.74** Rank the following in order of increasing electrical conductivity, and explain your ranking: Po, S, Se.

**14.75** The oxygen and nitrogen families have some obvious similarities and differences.

- (a) State two general physical similarities between Group 5A(15) and 6A(16) elements.  
 (b) State two general chemical similarities between Group 5A(15) and 6A(16) elements.  
 (c) State two chemical similarities between P and S.  
 (d) State two physical similarities between N and O.  
 (e) State two chemical differences between N and O.

**14.76** A molecular property of the Group 6A(16) hydrides changes abruptly down the group. This change has been explained in terms of a change in orbital hybridization.

- (a) Between what periods does the change occur?  
 (b) What is the change in the molecular property?  
 (c) What is the change in hybridization?  
 (d) What other group displays a similar change?

### Skill-Building Exercises (grouped in similar pairs)

**14.77** Complete and balance the following:

- (a)  $\text{NaHSO}_4(aq) + \text{NaOH}(aq) \longrightarrow$   
 (b)  $\text{S}_8(s) + \text{excess F}_2(g) \longrightarrow$   
 (c)  $\text{FeS}(s) + \text{HCl}(aq) \longrightarrow$   
 (d)  $\text{Te}(s) + \text{I}_2(s) \longrightarrow$

**14.78** Complete and balance the following:

- (a)  $\text{H}_2\text{S}(g) + \text{O}_2(g) \longrightarrow$   
 (b)  $\text{SO}_3(g) + \text{H}_2\text{O}(l) \longrightarrow$   
 (c)  $\text{SF}_4(g) + \text{H}_2\text{O}(l) \longrightarrow$   
 (d)  $\text{Al}_2\text{Se}_3(s) + \text{H}_2\text{O}(l) \longrightarrow$

**14.79** Is each oxide basic, acidic, or amphoteric in water?

- (a)  $\text{SeO}_2$  (b)  $\text{N}_2\text{O}_3$  (c)  $\text{K}_2\text{O}$   
 (d)  $\text{BeO}$  (e)  $\text{BaO}$

**14.80** Is each oxide basic, acidic, or amphoteric in water?

- (a)  $\text{MgO}$  (b)  $\text{N}_2\text{O}_5$  (c)  $\text{CaO}$   
 (d)  $\text{CO}_2$  (e)  $\text{TeO}_2$

**14.81** Rank the following hydrides in order of *increasing* acid strength:  $\text{H}_2\text{S}$ ,  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{Te}$ .

**14.82** Rank the following species in order of *decreasing* acid strength:  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{SO}_3$ ,  $\text{HSO}_3^-$ .

### Problems in Context

**14.83** Selenium tetrafluoride reacts with fluorine to form selenium hexafluoride.

- (a) Draw Lewis structures for both selenium fluorides, and predict any deviations from ideal bond angles.  
 (b) Describe the change in orbital hybridization of the central Se during the reaction.

**14.84** Give the name and symbol or formula of a Group 6A(16) element or compound that fits each description or use:

- (a) Unstable allotrope of oxygen  
 (b) Oxide having sulfur with the same O.N. as in sulfuric acid  
 (c) Air pollutant produced by burning sulfur-containing coal  
 (d) Powerful dehydrating agent  
 (e) Compound used in solution in the photographic process

**14.85** Give the oxidation state of sulfur in each substance:

- (a)  $\text{S}_8$  (b)  $\text{SF}_4$  (c)  $\text{SF}_6$   
 (d)  $\text{H}_2\text{S}$  (e)  $\text{FeS}_2$  (f)  $\text{H}_2\text{SO}_4$   
 (g)  $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$

**14.86** Disulfur decafluoride is intermediate in reactivity between  $\text{SF}_4$  and  $\text{SF}_6$ . It disproportionates at  $150^\circ\text{C}$  to these monosulfur fluorides. Write a balanced equation for this reaction, and give the oxidation state of S in each compound.

### Group 7A(17): The Halogens

#### Concept Review Questions

**14.87** (a) Give the physical state and color of each halogen at STP.  
 (b) Explain the change in physical state down Group 7A(17) in terms of molecular properties.

**14.88** (a) What are the common oxidation states of the halogens?  
 (b) Give an explanation based on electron configuration for the range and values of the oxidation states of chlorine.

(c) Why is fluorine an exception to the pattern of oxidation states found for the other group members?

**14.89** How many electrons does a halogen atom need to complete its octet? Give examples of the ways a Cl atom can do so.

**14.90** Select the stronger bond in each pair:

(a) Cl—Cl or Br—Br

(b) Br—Br or I—I

(c) F—F or Cl—Cl. Why doesn't the F—F bond strength follow the group trend?

**14.91** In addition to interhalogen compounds, many interhalogen ions exist. Would you expect interhalogen ions with a 1+ or a 1- charge to have an even or odd number of atoms? Explain.

**14.92** (a) A halogen ( $X_2$ ) disproportionates in base in several steps to  $X^-$  and  $XO_3^-$ . Write the overall equation for the disproportionation of  $Br_2$  in excess  $OH^-$  to  $Br^-$  and  $BrO_3^-$ .

(b) Write a balanced equation for the reaction of  $ClF_5$  with aqueous base (*Hint*: Add base to the reaction of  $BrF_5$  shown in Section 14.9).

### Skill-Building Exercises (grouped in similar pairs)

**14.93** Complete and balance the following equations. If no reaction occurs, write NR:

(a)  $Rb(s) + Br_2(l) \longrightarrow$

(b)  $I_2(s) + H_2O(l) \longrightarrow$

(c)  $Br_2(l) + I^-(aq) \longrightarrow$

(d)  $CaF_2(s) + H_2SO_4(l) \longrightarrow$

**14.94** Complete and balance the following equations. If no reaction occurs, write NR:

(a)  $H_3PO_4(l) + NaI(s) \longrightarrow$

(b)  $Cl_2(g) + I^-(aq) \longrightarrow$

(c)  $Br_2(l) + Cl^-(aq) \longrightarrow$

(d)  $ClF(g) + F_2(g) \longrightarrow$

**14.95** Rank the following acids in order of *increasing* acid strength:  $HClO$ ,  $HClO_2$ ,  $HBrO$ ,  $HIO$ .

**14.96** Rank the following acids in order of *decreasing* acid strength:  $HBrO_3$ ,  $HBrO_4$ ,  $HIO_3$ ,  $HClO_4$ .

### Problems in Context

**14.97** Give the name and symbol or formula of a Group 7A(17) element or compound that fits each description or use:

(a) Used in etching glass

(b) Compound used in household bleach

(c) Weakest hydrohalic acid

(d) Element that is a liquid at room temperature

(e) Organic chloride used to make PVC

**14.98** An industrial chemist treats solid  $NaCl$  with concentrated  $H_2SO_4$  and obtains gaseous  $HCl$  and  $NaHSO_4$ . When she substitutes solid  $NaI$  for  $NaCl$ , she obtains gaseous  $H_2S$ , solid  $I_2$ , and  $S_8$ , but no  $HI$ .

(a) What type of reaction did the  $H_2SO_4$  undergo with  $NaI$ ?

(b) Why does  $NaI$ , but not  $NaCl$ , cause this type of reaction?

(c) To produce  $HI(g)$  by reacting  $NaI$  with an acid, how does the acid have to differ from sulfuric acid?

**14.99** Rank the halogens  $Cl_2$ ,  $Br_2$ , and  $I_2$  in order of increasing oxidizing strength based on their products with the metal rhenium (Re):  $ReCl_6$ ,  $ReBr_5$ ,  $ReI_4$ . Explain your ranking.

### Group 8A(18): The Noble Gases

**14.100** Which noble gas is the most abundant in the universe? In Earth's atmosphere?

**14.101** What oxidation states does Xe show in its compounds?

**14.102** Why do the noble gases have such low boiling points?

**14.103** Explain why Xe, and to a limited extent Kr, form compounds, whereas He, Ne, and Ar do not.

**14.104** (a) Why do stable xenon fluorides have an even number of F atoms?

(b) Why do the ionic species  $XeF_3^+$  and  $XeF_7^-$  have odd numbers of F atoms?

(c) Predict the shape of  $XeF_3^+$ .

### Comprehensive Problems

**14.105** Xenon tetrafluoride reacts with antimony pentafluoride to form the ionic complex  $[XeF_3]^+[SbF_6]^-$ .

(a) Which depiction shows the molecular shapes of the reactants and product?

(b) How, if at all, does the hybridization of xenon change in the reaction?

**14.106** Given the following information,

calculate the heat of solution of the hydronium ion:

**14.107** The electronic transition in Na from  $3p^1$  to  $3s^1$  gives rise to a bright yellow-orange emission at 589.2 nm. What is the energy of this transition?

**14.108** Unlike other Group 2A(2) metals, beryllium reacts like aluminum and zinc with concentrated aqueous base to release hydrogen gas and form oxoanions of formula  $M(OH)_4^{n-}$ . Write equations for the reactions of these three metals with  $NaOH$ .

**14.109** The interhalogen  $IF$  undergoes the reaction depicted below ( $I$  is purple and  $F$  is green):

(a) Write the balanced equation. (b) Name the interhalogen product.

(c) What type of reaction is shown? (d) If each molecule of  $IF$  represents  $2.50 \times 10^{-3}$  mol, what mass of each product forms?

**14.110** The main reason alkali metal dihalides ( $\text{MX}_2$ ) do *not* form is the high  $\text{IE}_2$  of the metal.

- (a) Why is  $\text{IE}_2$  so high for alkali metals?  
 (b) The  $\text{IE}_2$  for Cs is 2255 kJ/mol, low enough for  $\text{CsF}_2$  to form exothermically ( $\Delta H_f^\circ = -125$  kJ/mol). This compound cannot be synthesized, however, because CsF forms with a much greater release of heat ( $\Delta H_f^\circ = -530$  kJ/mol). Thus, the breakdown of  $\text{CsF}_2$  to CsF happens readily. Write the equation for this breakdown, and calculate the enthalpy of reaction per mole of CsF.

**14.111** Semiconductors made from elements in Groups 3A(13) and 5A(15) are typically prepared by direct reaction of the elements at high temperature. An engineer treats 32.5 g of molten gallium with 20.4 L of white phosphorus vapor at 515 K and 195 kPa. If purification losses are 7.2% by mass, how many grams of gallium phosphide will be prepared?

**14.112** Two substances with the empirical formula HNO are hyponitrous acid ( $\mathcal{M} = 62.04$  g/mol) and nitroxyl ( $\mathcal{M} = 31.02$  g/mol).

- (a) What is the molecular formula of each species?  
 (b) For each species, draw the Lewis structure having the lowest formal charges. (*Hint*: Hyponitrous acid has an  $\text{N}=\text{N}$  bond.)  
 (c) Predict the shape around the N atoms of each species.  
 (d) When hyponitrous acid loses two protons, it forms the hyponitrite ion. Draw *cis* and *trans* forms of this ion.

**14.113** The species CO,  $\text{CN}^-$ , and  $\text{C}_2^{2-}$  are isoelectronic.

- (a) Draw their Lewis structures.  
 (b) Draw their MO diagrams (assume mixing of  $2s$  and  $2p$  orbitals, as in  $\text{N}_2$ ), and give the bond order and electron configuration for each.

**14.114** The Ostwald process is a series of three reactions used for the industrial production of nitric acid from ammonia.

- (a) Write a series of balanced equations for the Ostwald process.  
 (b) If NO is *not* recycled, how many moles of  $\text{NH}_3$  are consumed per mole of  $\text{HNO}_3$  produced?  
 (c) In a typical industrial unit, the process is very efficient, with a 96% yield for the first step. Assuming 100% yields for the subsequent steps, what volume of concentrated aqueous nitric acid (60.% by mass;  $d = 1.37$  g/mL) can be prepared for each cubic meter of a gas mixture that is 90.% air and 10.%  $\text{NH}_3$  by volume at the industrial conditions of 5.0 atm and 850.°C?

**14.115** All common plant fertilizers contain nitrogen compounds. Determine the mass % of N in each compound:

- (a) Ammonia  
 (b) Ammonium nitrate  
 (c) Ammonium hydrogen phosphate

**14.116** Producer gas is a fuel formed by passing air over red-hot coke (amorphous carbon). What mass of a producer gas that consists of 25% CO, 5.0%  $\text{CO}_2$ , and 70.%  $\text{N}_2$  by mass can be formed from 1.75 metric tons (t) of coke, assuming an 87% yield?

**14.117** Gaseous  $\text{F}_2$  reacts with water to form HF and  $\text{O}_2$ . In NaOH solution,  $\text{F}_2$  forms  $\text{F}^-$ , water, and oxygen difluoride ( $\text{OF}_2$ ), a highly toxic gas and powerful oxidizing agent. The  $\text{OF}_2$  reacts with excess  $\text{OH}^-$ , forming  $\text{O}_2$ , water, and  $\text{F}^-$ .

- (a) For each reaction, write a balanced equation, give the oxidation state of O in all compounds, and identify the oxidizing and reducing agents.  
 (b) Draw a Lewis structure for  $\text{OF}_2$ , and predict its shape.

**14.118** What is a disproportionation reaction, and which of the following fit the description?

- (a)  $\text{I}_2(s) + \text{KI}(aq) \longrightarrow \text{KI}_3(aq)$   
 (b)  $2\text{ClO}_2(g) + \text{H}_2\text{O}(l) \longrightarrow \text{HClO}_3(aq) + \text{HClO}_2(aq)$   
 (c)  $\text{Cl}_2(g) + 2\text{NaOH}(aq) \longrightarrow \text{NaCl}(aq) + \text{NaClO}(aq) + \text{H}_2\text{O}(l)$   
 (d)  $\text{NH}_4\text{NO}_2(s) \longrightarrow \text{N}_2(g) + 2\text{H}_2\text{O}(g)$   
 (e)  $3\text{MnO}_4^{2-}(aq) + 2\text{H}_2\text{O}(l) \longrightarrow$   
 $2\text{MnO}_4^-(aq) + \text{MnO}_2(s) + 4\text{OH}^-(aq)$   
 (f)  $3\text{AuCl}(s) \longrightarrow \text{AuCl}_3(s) + 2\text{Au}(s)$

**14.119** Explain the following observations:

- (a) In reactions with  $\text{Cl}_2$ , phosphorus forms  $\text{PCl}_5$  in addition to the expected  $\text{PCl}_3$ , but nitrogen forms only  $\text{NCl}_3$ .  
 (b) Carbon tetrachloride is unreactive toward water, but silicon tetrachloride reacts rapidly and completely. (To give what?)  
 (c) The sulfur-oxygen bond in  $\text{SO}_4^{2-}$  is shorter than expected for an S—O single bond.  
 (d) Chlorine forms  $\text{ClF}_3$  and  $\text{ClF}_5$ , but  $\text{ClF}_4$  is unknown.

**14.120** Which group(s) of the periodic table is (are) described by each of the following general statements?

- (a) The elements form compounds of VSEPR class  $\text{AX}_3\text{E}$ .  
 (b) The free elements are strong oxidizing agents and form monatomic ions and oxoanions.  
 (c) The atoms form compounds by combining with two other atoms that donate one electron each.  
 (d) The free elements are strong reducing agents, show only one nonzero oxidation state, and form mainly ionic compounds.  
 (e) The elements can form stable compounds with only three bonds, but as a central atom, they can accept a pair of electrons from a fourth atom without expanding their valence shell.  
 (f) Only larger members of the group are chemically active.

**14.121** Diiodine pentoxide ( $\text{I}_2\text{O}_5$ ) was discovered by Joseph Gay-Lussac in 1813, but its structure was unknown until 1970! Like  $\text{Cl}_2\text{O}_7$ , it can be prepared by the dehydration-condensation of the corresponding oxoacid.

- (a) Name the precursor oxoacid, write a reaction for formation of the oxide, and draw a likely Lewis structure.  
 (b) Data show that the bonds to the terminal O are shorter than the bonds to the bridging O. Why?  
 (c)  $\text{I}_2\text{O}_5$  is one of the few chemicals that can oxidize CO rapidly and completely; elemental iodine forms in the process. Write a balanced equation for this reaction.

**14.122** Bromine monofluoride ( $\text{BrF}$ ) disproportionates to bromine gas and bromine trifluoride or pentafluoride. Use the following to find  $\Delta H_{\text{rxn}}^\circ$  for the decomposition of  $\text{BrF}$  to its elements:

**14.123** White phosphorus is prepared by heating phosphate rock [principally  $\text{Ca}_3(\text{PO}_4)_2$ ] with sand and coke:

How many kilograms of phosphate rock are needed to produce 315 mol of  $\text{P}_4$ , assuming that the conversion is 90.% efficient?

- 14.124** Element E forms an oxide of general structure A and a chloride of general structure B, shown at right. For the anion  $\text{EF}_5^-$ , what is (a) the molecular shape; (b) the hybridization of E; (c) the O.N. of E?

**14.125** From its formula, one might expect CO to be quite polar, but its dipole moment is actually small (0.11 D).

- (a) Draw the Lewis structure for CO.  
 (b) Calculate the formal charges.  
 (c) Based on your answers to parts (a) and (b), explain why the dipole moment is so small.

**14.126** When an alkaline earth carbonate is heated, it releases CO<sub>2</sub>, leaving the metal oxide. The temperature at which each Group 2A(2) carbonate yields a CO<sub>2</sub> partial pressure of 1 atm is listed below:

Carbonate	Temperature (°C)
MgCO <sub>3</sub>	542
CaCO <sub>3</sub>	882
SrCO <sub>3</sub>	1155
BaCO <sub>3</sub>	1360

- (a) Suggest a reason for this trend.  
 (b) Mixtures of CaCO<sub>3</sub> and MgO are used to absorb dissolved silicates from boiler water. How would you prepare a mixture of CaCO<sub>3</sub> and MgO from dolomite, which contains CaCO<sub>3</sub> and MgCO<sub>3</sub>?

**14.127** The bond angles in the nitrite ion, nitrogen dioxide, and the nitronium ion (NO<sub>2</sub><sup>+</sup>) are 115°, 134°, and 180°, respectively. Explain these values using Lewis structures and VSEPR theory.

**14.128** A common method for producing a gaseous hydride is to treat a salt containing the anion of the volatile hydride with a strong acid.

- (a) Write an equation for each of the following examples: (1) the production of HF from CaF<sub>2</sub>; (2) the production of HCl from NaCl; (3) the production of H<sub>2</sub>S from FeS.  
 (b) In some cases, even as weak an acid as water can be used for this preparation if the anion of the salt has a sufficiently strong attraction for protons. An example is the production of PH<sub>3</sub> from Ca<sub>3</sub>P<sub>2</sub> and water. Write the equation for this reaction.  
 (c) By analogy, predict the products and write the equation for the reaction of Al<sub>4</sub>C<sub>3</sub> with water.

**14.129** Chlorine trifluoride was formerly used in the production of uranium hexafluoride for the U.S. nuclear industry:

How many grams of UF<sub>6</sub> can form from 1.00 metric ton of uranium ore that is 1.55% by mass uranium and 12.75 L of chlorine trifluoride ( $d = 1.88 \text{ g/mL}$ )?

**14.130** Chlorine is used to make bleach solutions containing 5.25% NaClO (by mass). Assuming 100% yield in the reaction producing NaClO from Cl<sub>2</sub>, how many liters of Cl<sub>2</sub>(g) at STP will be needed to make 1000. L of bleach solution ( $d = 1.07 \text{ g/mL}$ )?

**14.131** The triatomic molecular ion H<sub>3</sub><sup>+</sup> was first detected and characterized by J. J. Thomson using H<sub>3</sub><sup>+</sup> mass spectrometry. Use the bond energy of H<sub>2</sub> (432 kJ/mol) and the proton affinity of H<sub>2</sub> (H<sub>2</sub> + H<sup>+</sup> → H<sub>3</sub><sup>+</sup>;  $\Delta H = -337 \text{ kJ/mol}$ ) to calculate the enthalpy of reaction for H + H + H<sup>+</sup> → H<sub>3</sub><sup>+</sup>.

**14.132** An atomic hydrogen torch is used for cutting and welding thick sheets of metal. When H<sub>2</sub> passes through an electric arc, the molecules decompose into atoms, which react with O<sub>2</sub>. Temperatures over 5000°C are reached, which can melt all metals. Write equations for the breakdown of H<sub>2</sub> to H atoms and for the subsequent overall reaction of the H atoms with oxygen. Use Appendix B to find the standard enthalpy of each reaction per mole of product.

**14.133** Which of the following oxygen ions are paramagnetic: O<sup>+</sup>, O<sup>-</sup>, O<sup>2-</sup>, O<sup>2+</sup>?

**14.134** Copper(II) hydrogen arsenite (CuHAsO<sub>3</sub>) is a green pigment once used in wallpaper. In damp conditions, mold metabolizes this compound to trimethylarsine [(CH<sub>3</sub>)<sub>3</sub>As], a highly toxic gas.

- (a) Calculate the mass percent of As in each compound.  
 (b) How much CuHAsO<sub>3</sub> must react to reach a toxic level in a room that measures 12.35 m × 7.52 m × 2.98 m (arsenic is toxic at 0.50 mg/m<sup>3</sup>)?

**14.135** Hydrogen peroxide can act as either an oxidizing agent or a reducing agent.

- (a) When H<sub>2</sub>O<sub>2</sub> is treated with aqueous KI, I<sub>2</sub> forms. In which role is H<sub>2</sub>O<sub>2</sub> acting? What oxygen-containing product is formed?  
 (b) When H<sub>2</sub>O<sub>2</sub> is treated with aqueous KMnO<sub>4</sub>, the purple color of MnO<sub>4</sub><sup>-</sup> disappears and a gas forms. In which role is H<sub>2</sub>O<sub>2</sub> acting? What is the oxygen-containing product formed?

## Concepts and Skills to Review Before You Study This Chapter

- › naming straight-chain alkanes (Section 2.8)
- › constitutional isomerism (Section 3.2)
- ›  $\Delta EN$  and bond polarity (Section 9.5)
- › resonance structures (Section 10.1)
- › VSEPR theory (Section 10.2)
- › orbital hybridization (Section 11.1)
- ›  $\sigma$  and  $\pi$  bonding (Section 11.2)
- › intermolecular forces and synthetic and biological macromolecules (Sections 12.3, 12.7, and 13.2)
- › properties of the Period 2 elements (Section 14.2)
- › properties of the Group 4A(14) elements (Section 14.6)

If you eat a snack during a study break, chances are you will consume organic compounds from containers composed of more organic compounds! Milk, apples, and cookies contain carbohydrates, fats, and proteins, and the plastic milk container and plate are a combination of polymeric organic compounds. In fact, except for a few inorganic salts and ever-present water, nearly everything you put into or on your body—food, medicine, cosmetics, and clothing—consists of organic compounds. Organic fuels warm our homes, cook our meals, and power our vehicles. Major industries are devoted to producing organic compounds, including plastics, pharmaceuticals, and insecticides.

What *is* an organic compound? According to the dictionary, it is “a compound of carbon,” but that definition is too general because carbonates, cyanides, carbides, cyanates, and so forth, also contain carbon but are classified as inorganic. Here is a more specific definition: all **organic compounds** contain carbon, nearly always bonded to one or more other carbons and to hydrogen, and often to other elements.

In the early 19<sup>th</sup> century, organic compounds were usually obtained from living things, so they were thought to possess a spiritual “vital force,” which made them impossible to synthesize and fundamentally different from inorganic compounds. But, in 1828, Friedrich Wöhler destroyed this notion when he obtained urea by heating ammonium cyanate. Today, we know that *the same chemical principles govern organic and inorganic systems* because the behavior of a compound—no matter how amazing—can be explained by understanding the properties of its elements.

**IN THIS CHAPTER . . .** We see that the structures and reactivities of organic molecules emerge naturally from the properties of their component atoms.

- › We begin by reviewing the atomic properties of carbon and seeing how they lead to the complex structures and reactivity of organic molecules.
- › We focus on drawing and naming hydrocarbons as a prelude to naming other types of organic compounds.
- › We classify the main types of organic reactions in terms of bond order and apply them to the functional groups that characterize families of organic compounds.
- › We examine the giant organic molecules of commerce and life—synthetic and natural polymers.

### 15.1 THE SPECIAL NATURE OF CARBON AND THE CHARACTERISTICS OF ORGANIC MOLECULES

Although there is nothing mystical about organic molecules, their indispensable role in biology and industry leads us to wonder if carbon is somehow special. Of course, each element has specific properties, but the atomic properties of carbon do give it bonding capabilities beyond those of any element, and this exceptional behavior

leads to the two characteristics of organic molecules—structural complexity and chemical diversity.

## The Structural Complexity of Organic Molecules

Most organic molecules have more complex structures than most inorganic molecules. A quick review of carbon's atomic properties and bonding behavior shows why.

**Figure 15.1** The position of carbon in the periodic table.

1. *Electron configuration, electronegativity, and bonding.* Carbon forms covalent, rather than ionic, bonds in all its elemental forms and compounds. This bonding behavior is the result of carbon's electron configuration and electronegativity:

- Carbon's ground-state electron configuration of  $[\text{He}] 2s^2 2p^2$ —four electrons more than He and four fewer than Ne—means that the formation of carbon ions is energetically impossible under ordinary conditions. The loss of four  $e^-$  to form the  $\text{C}^{4+}$  cation requires the sum of  $\text{IE}_1$  through  $\text{IE}_4$  ( $>14,000$  kJ/mol!); the gain of four  $e^-$  to form the  $\text{C}^{4-}$  anion requires the sum of  $\text{EA}_1$  through  $\text{EA}_4$ , the last three steps of which are endothermic.
- Lying at the center of Period 2, carbon has an electronegativity ( $\text{EN} = 2.5$ ) that is midway between that of the most metallic element (Li,  $\text{EN} = 1.0$ ) and the most nonmetallic active element (F,  $\text{EN} = 4.0$ ) (Figure 15.1).

2. *Catenation, bond properties, and molecular shape.* The number and strength of carbon's bonds lead to its property of **catenation**, the ability to bond to one or more other carbon atoms, which results in a multitude of chemically and thermally stable chain, ring, and branched compounds:

- Through the process of orbital hybridization (Section 11.1), carbon forms four bonds in virtually all its compounds, and they point in as many as four different directions.
- The small size of carbon allows close approach to another atom and thus greater orbital overlap, so carbon forms relatively short, strong bonds.
- The C—C bond is short enough to allow side-to-side overlap of half-filled, unhybridized  $p$  orbitals and the formation of multiple bonds. These restrict rotation of attached groups (see Figure 11.14), leading to additional structures.

3. *Molecular stability.* Although silicon and several other elements also catenate, none forms chains as stable as those of carbon. Atomic and bonding properties explain why carbon chains are so stable and, therefore, so common:

- *Atomic size and bond strength.* As atomic size increases down Group 4A(14), bonds between identical atoms become longer and weaker. Thus, a C—C bond (347 kJ/mol) is much stronger than an Si—Si bond (226 kJ/mol).
- *Relative enthalpies of reaction.* A C—C bond (347 kJ/mol), a C—O bond (358 kJ/mol), and a C—Cl bond (339 kJ/mol) have nearly the same energy, so relatively little heat is released when a C chain reacts and one bond replaces the other. In contrast, an Si—O bond (368 kJ/mol) or an Si—Cl bond (381 kJ/mol) is much stronger than an Si—Si bond (226 kJ/mol), so the large quantity of heat released when an Si chain reacts favors reactivity.
- *Orbitals available for reaction.* Unlike C, Si has low-energy  $d$  orbitals that can be attacked (occupied) by the lone pairs of incoming reactants. Thus, for example, ethane ( $\text{CH}_3\text{—CH}_3$ ) is stable in water and reacts in air only when sparked, whereas disilane ( $\text{SiH}_3\text{—SiH}_3$ ) breaks down in water and ignites spontaneously in air.

## The Chemical Diversity of Organic Molecules

In addition to their complex structures, organic compounds are remarkable for their sheer number and diverse chemical behavior. Several million organic compounds are known, and thousands more are discovered or synthesized each year. This diversity is also founded on atomic behavior and is due to three interrelated factors—bonding to heteroatoms, variations in reactivity, and the occurrence of functional groups.

1. *Bonding to heteroatoms.* Many organic compounds contain **heteroatoms**, atoms other than C or H. The most common heteroatoms are N and O, but S, P, and the halogens often occur, and organic compounds with other elements are known as well. Figure 15.2 shows that 23 different molecular structures are possible from various arrangements of four C atoms singly bonded to each other, just one O atom (either singly or doubly bonded), and the necessary number of H atoms.

2. *Electron density and reactivity.* Most reactions start—that is, a new bond begins to form—when a region of high electron density on one molecule meets a region of low electron density on another. These regions may be due to the properties of a multiple bond or a carbon-heteroatom bond. Consider the reactivities of four bonds commonly found in organic molecules:

- *The C—C bond.* When C is singly bonded to another C, as occurs in portions of nearly every organic molecule, the EN values are equal and the bond is nonpolar. Therefore, in most cases, *C—C bonds are unreactive.*
- *The C—H bond.* This bond, which also occurs in nearly every organic molecule, is short (109 pm) and, with EN values of 2.1 for H and 2.5, very nearly nonpolar. Thus, *C—H bonds are largely unreactive.*
- *The C—O bond.* This bond, which occurs in many types of organic molecules, is highly polar ( $\Delta\text{EN} = 1.0$ ), with the O end electron rich and the C end electron poor. As a result of this imbalance in electron density, *the C—O bond is reactive* (easy to break), and, given appropriate conditions, a reaction will occur there.
- *Bonds to other heteroatoms.* Even when a carbon-heteroatom bond has a small  $\Delta\text{EN}$ , such as that for C—Br ( $\Delta\text{EN} = 0.3$ ), or none at all, as for C—S ( $\Delta\text{EN} = 0$ ), the heteroatoms are generally large, so their bonds to carbon are long, weak, and thus *reactive.*

3. *Importance of functional groups.* The central feature of most organic molecules is the **functional group**, a specific combination of bonded atoms that reacts in a characteristic way no matter what molecule it occurs in. In nearly every case, *the reaction of an organic compound takes place at the functional group.* (In fact, as you'll see in Section 15.3, we often write a general symbol for the remainder of the molecule because it stays the same while the functional group reacts.) Functional groups vary from carbon-carbon multiple bonds to several combinations of carbon-heteroatom bonds, and each has its own pattern of reactivity. A particular bond may be a functional group itself or *part* of one or more functional groups. For example, the C—O bond occurs in four functional groups. We will discuss the reactivity of three of these groups in this chapter:

**Figure 15.2** Heteroatoms and different bonding arrangements lead to great chemical diversity among organic molecules.

## › Summary of Section 15.1

- › Carbon's small size, intermediate electronegativity, four valence electrons, and ability to form multiple bonds result in the structural complexity of organic compounds.
- › These factors lead to carbon's ability to catenate, which creates chains, branches, and rings of C atoms. Small size and the absence of *d* orbitals in the valence level lead to strong, chemically resistant bonds that point in as many as four directions from each C.
- › Carbon's ability to bond to many other elements, especially O and N, creates polar, reactive bonds, which leads to the chemical diversity of organic compounds.
- › Most organic compounds contain functional groups, specific combinations of bonded atoms that react in characteristic ways.

## 15.2 THE STRUCTURES AND CLASSES OF HYDROCARBONS

Let's make an anatomical analogy between an organic molecule and an animal. The carbon-carbon bonds form the skeleton: the longest continual chain is the backbone, and any branches are the limbs. Covering the skeleton is a skin of hydrogen atoms, with functional groups protruding at specific locations, like chemical hands ready to grab an incoming reactant. In this section, we "dissect" one group of compounds down to their skeletons and see how to draw and name them.

**Hydrocarbons**, the simplest type of organic compound, contain only H and C atoms. Some common fuels, such as natural gas and gasoline, are hydrocarbon mixtures. Some hydrocarbons, such as ethylene, acetylene, and benzene, are important *feedstocks*, that is, precursor reactants used to make other compounds.

### Carbon Skeletons and Hydrogen Skins

We'll begin by examining the possible bonding arrangements of C atoms only (leaving off the H atoms for now) in simple skeletons without multiple bonds or rings. To distinguish different skeletons, focus on the *arrangement* of C atoms (that is, the successive linkages of one to another) and keep in mind that *groups joined by a single (sigma) bond are relatively free to rotate* (Section 11.2).

**Number of C Atoms and Number of Arrangements** One, two, or three C atoms can be arranged in only one way. Whether you draw three C atoms in a line or with a bend, the arrangement is the same. Four C atoms, however, have two possible arrangements—a four-C chain or a three-C chain with a one-C branch at the central C:

When we show the chains with bends due to the tetrahedral C (as in the ball-and-stick models above), the different arrangements are especially clear. Notice that if the branch is added to either end of the three-C chain, it is simply a bend in a four-C chain, *not* a different arrangement. Similarly, if the branch points down instead of up, it represents the same arrangement because single-bonded groups rotate.

As the total number of C atoms increases, the number of different arrangements increases as well. Five C atoms joined by single bonds have 3 possible arrangements (Figure 15.3A); 6 C atoms can be arranged in 5 ways, 7 C atoms in 9 ways, 10 C atoms in 75 ways, and 20 C atoms in more than 300,000 ways! If we include multiple bonds and rings, the number of arrangements increases further. For example,

**Figure 15.3** Some five-carbon skeletons.

including just one C=C bond in the five-C skeletons creates 5 more arrangements (Figure 15.3B), and including one ring creates 5 more (Figure 15.3C).

**Drawing Hydrocarbons** When determining the number of different skeletons for a given number of C atoms, remember that

- Each C atom can form four single bonds, two single and one double bond, or one single and one triple bond:

- A straight chain or a bent chain of C atoms represent the same skeleton.
- For a single-bonded arrangement, a branch pointing down is the same as one pointing up.
- A double bond *restricts rotation*, so different groups joined by a double bond can result in different arrangements.

If we put a hydrogen “skin” on a carbon skeleton, we obtain a hydrocarbon. Figure 15.4 shows that a skeleton has the correct number of H atoms *when each C has a total of four bonds*. Sample Problem 15.1 provides practice drawing hydrocarbons.

**Figure 15.4** Adding the H-atom skin to the C-atom skeleton.

### SAMPLE PROBLEM 15.1

### Drawing Hydrocarbons

**Problem** Draw structures that have different atom arrangements for hydrocarbons with:

- Six C atoms, no multiple bonds, and no rings
- Four C atoms, one double bond, and no rings
- Four C atoms, no multiple bonds, and one ring

**Plan** In each case, we draw the longest carbon chain first and then work down to smaller chains with branches at different points along them. The process typically involves trial and error. Then, we add H atoms to give each C a total of four bonds.

**Solution** (a) Compounds with six C atoms:

(b) Compounds with four C atoms and one double bond:

(c) Compounds with four C atoms and one ring:

**Check** Be sure each skeleton has the correct number of C atoms, multiple bonds, and/or rings, and no arrangements are repeated or omitted; remember a double bond counts as two bonds.

**Comment** Avoid some *common mistakes*:

In (b):  is the same skeleton as 

The double bond restricts rotation, so, in addition to the *cis* form shown on the left of the 4-C chains in the solution for part (b), another possibility is the *trans* form:

(We discuss *cis* and *trans* forms fully later in this section.)

Also, avoid drawing too many bonds to one C, as here: 

In (c): there would be too many bonds to one C in 

### FOLLOW-UP PROBLEMS

*Brief Solutions to all Follow-up Problems appear at the end of the chapter.*

**15.1A** Draw all hydrocarbons that have different atom arrangements with (a) seven C atoms, no multiple bonds, and no rings (nine arrangements); (b) five C atoms, one triple bond, and no rings (three arrangements).

**15.1B** Draw all hydrocarbons that have different atom arrangements with (a) four C atoms, one ring, and one double bond (four arrangements); (b) four C atoms, no rings, and two double bonds (two arrangements).

**SOME SIMILAR PROBLEMS** 15.13–15.16

Hydrocarbons can be classified into four main groups: alkanes, alkenes, alkynes, and aromatics. In the rest of this section, we discuss how to name them, as well as some structural features and physical properties of each group. Later, we'll discuss the chemical behavior of the hydrocarbons.

## Alkanes: Hydrocarbons with Only Single Bonds

Hydrocarbons that contain only single bonds are **alkanes** and have the following general features:

- Alkanes have the general formula  $C_nH_{2n+2}$ , where  $n$  is a positive integer. For example, if  $n = 5$ , the formula is  $C_5H_{(2 \times 5) + 2}$ , or  $C_5H_{12}$ .
- The alkanes comprise a **homologous series**, one in which each member differs from the next by a  $-CH_2-$  (methylene) group.
- In an alkane, each C is  $sp^3$  hybridized.
- Because each C is bonded to the *maximum number (4) of other atoms* (C or H), alkanes are referred to as **saturated hydrocarbons**.

**Naming Alkanes** You learned the names of the 10 smallest straight-chain alkanes in Section 2.8. Here we discuss the rules for naming any alkane and, by extension, other organic compounds as well. The key point is that *each chain, branch, or ring has a name based on the number of C atoms*. The name of a compound has three portions:

PREFIX + ROOT + SUFFIX

- Root:** The root tells the number of C atoms in the longest *continuous* chain in the molecule. The roots for the ten smallest alkanes are listed in Table 15.1. As you can see, there are special roots for compounds with chains of one to four C atoms; roots of longer chains are based on Greek numbers.
- Suffix:** The suffix tells the *type of organic compound* that is being named; that is, it identifies the key functional group the molecule possesses. The suffix is placed *after* the root.
- Prefix:** Each prefix identifies a *group attached to the main chain* and the number of the carbon atom to which it is attached. Prefixes identifying hydrocarbon branches are the same as root names (Table 15.1) but have *-yl* as their ending; for example, a two-carbon branch is an ethyl group. Each prefix is placed *before* the root.

For example, in the name 2-methylbutane, *2-methyl-* is the prefix, *-but-* is the root, and *-ane* is the suffix, with each portion indicating information about the molecular structure:

To obtain the systematic name of a compound,

- Name the longest chain (ROOT).
- Add the compound type (SUFFIX).
- Name any branches (PREFIX).

Table 15.2 on the next page presents the rules for naming any organic compound and applies them to an alkane component of gasoline. Other organic compounds are named with a variety of other prefixes and suffixes (see Table 15.5). In addition to these *systematic* names, as you'll see, some *common* names are still in use.

**Depicting Alkanes with Formulas and Models** Chemists have several ways to depict organic compounds. Expanded, condensed, and carbon-skeleton formulas are easy to draw; ball-and-stick and space-filling models show the actual shapes and bond angles:

- The *expanded formula* is a Lewis structure, so it shows each atom and bond.
- One type of *condensed formula* groups each C atom with its H atoms; not all bonds are shown.
- The *carbon-skeleton formula* shows only carbon-carbon bonds and appears as a zig-zag line, with one or more branches as needed. *Each end or bend of a line or*

Table 15.2

## Rules for Naming an Organic Compound

- Naming the longest chain (root)
  - Find the longest *continuous* chain of C atoms.
  - Select the root that corresponds to the number of C atoms in this chain.
- Naming the compound type (suffix)
  - For alkanes, add the suffix *-ane* to the chain root. (Other suffixes appear in Table 15.5 with their functional group and compound type.)
  - If the chain forms a ring, the name is preceded by *cyclo-*.
- Naming the branches (prefixes) (If the compound has no branches, the name consists only of the root and suffix.)
  - Each branch name consists of a root (indicating the number of C atoms) and the ending *-yl* to signify that it is not part of the main chain.
  - Branch names precede the chain name. When two or more branches are present, their names appear in *alphabetical* order.
  - To specify where a branch occurs along the chain, number the main-chain C atoms consecutively, starting at the end *closer* to the first branch, to achieve the *lowest* numbers for all the branches. Precede each branch name with the number of the main-chain C to which that branch is attached.

hex- + *-ane*  $\Rightarrow$  hexane

branch represents a C atom attached to the number of H atoms that gives it four bonds:

Figure 15.5 shows the formulas (and models) of the compound named in Table 15.2.

**Cyclic Hydrocarbons** A **cyclic hydrocarbon** contains one or more rings. When a straight-chain alkane ( $C_nH_{2n+2}$ ) forms a ring, two H atoms are lost as the two ends of the chain form a C—C bond. Thus, *cycloalkanes* have the general formula  $C_nH_{2n}$ . Cyclic hydrocarbons are often drawn with carbon-skeleton formulas (Figure 15.6, *top row*). Except for three-carbon rings, *cycloalkanes are nonplanar*, as the ball-and-stick and space-filling models show. This structural feature arises from the tetrahedral shape around each C atom and the need to minimize electron repulsions between adjacent H atoms. The most stable form of cyclohexane is called the *chair conformation* (see the ball-and-stick model in Figure 15.6D).

Figure 15.5 Ways of depicting the alkane 3-ethyl-2-methylhexane.

Figure 15.6 Depicting cycloalkanes.

## Dispersion Forces and the Physical Properties of Alkanes

Because alkanes are nearly nonpolar, we expect their physical properties and solubility behavior to be determined by dispersion forces (Section 12.3). A particularly clear example of this effect occurs among the unbranched alkanes (*n*-alkanes). Boiling points increase steadily with chain length (Figure 15.7): the longer the chain, the greater the molar mass and the greater the intermolecular contact, the stronger the dispersion forces, and, thus, the higher the boiling point. Pentane (five C atoms) is the smallest *n*-alkane that exists as a liquid at room temperature.

The solubility of alkanes, and of all hydrocarbons, is easy to predict from the like-dissolves-like rule (Section 13.1). Alkanes are miscible in each other and in other nonpolar solvents, such as benzene, but are nearly insoluble in water. The solubility of pentane in water, for example, is only 0.36 g/L at room temperature.

## Constitutional Isomerism

Recall from Section 3.2 that two or more compounds that have the same molecular formula but different properties are called **isomers**. Those with *different arrangements*

Figure 15.7 Formulas, molar masses ( $\mathcal{M}$ , in g/mol), structures, and boiling points ( $^{\circ}\text{C}$ , at 1 atm pressure) of the first 10 unbranched alkanes.

Table 15.3

The Constitutional Isomers of  $C_4H_{10}$  and  $C_5H_{12}$ 

Systematic Name (Common Name)	Expanded Formula	Condensed and Skeleton Formulas	Space-Filling Model	Density (g/mL)	Boiling Point ( $^{\circ}C$ )
<b>Butane</b> ( <i>n</i> -butane)		$CH_3-CH_2-CH_2-CH_3$ 		0.579	-0.5
<b>2-Methylpropane</b> (isobutane)		$CH_3-CH-CH_3$ 		0.549	-11.6
<b>Pentane</b> ( <i>n</i> -pentane)		$CH_3-CH_2-CH_2-CH_2-CH_3$ 		0.626	36.1
<b>2-Methylbutane</b> (isopentane)		$CH_3-CH-CH_2-CH_3$ 		0.620	27.8
<b>2,2-Dimethylpropane</b> (neopentane)		$CH_3-C(CH_3)_2-CH_3$ 		0.614	9.5

of bonded atoms are **constitutional** (or **structural**) **isomers**; alkanes with the same number of C atoms but different skeletons are examples. The smallest alkane to exhibit constitutional isomerism has four C atoms,  $C_4H_{10}$ ; its two isomers are shown in the top of Table 15.3. The unbranched isomer is butane (common name, *n*-butane; *n*- stands for “normal,” or having a straight chain), and the other is 2-methylpropane (common name, *isobutane*). Similarly, the bottom three isomers in the table have the formula  $C_5H_{12}$ . The unbranched isomer is pentane (common name, *n*-pentane); the one with a methyl branch at C-2 of a four-C chain is 2-methylbutane (common name, *isopentane*). The third isomer has two methyl branches on C-2 of a three-C chain, so its name is 2,2-dimethylpropane (common name, *neopentane*).

As expected, the physical properties of constitutional isomers depend on the strength of the dispersion forces; this relationship is demonstrated by boiling points (Table 15.3, *rightmost column*).

- The four-C compounds boil lower than the five-C compounds since the strength of dispersion forces generally increases with increasing molar mass.
- Within each group, the more spherical member (*isobutane* or *neopentane*) boils lower than the more elongated one (*n*-butane or *n*-pentane). Recall that a spherical shape allows less intermolecular contact, and thus lower total dispersion forces, than does an elongated shape (see Figure 12.18).

### Chiral Molecules and Optical Isomerism

Another type of isomerism exhibited by some alkanes and many other organic (as well as some inorganic) compounds is called *stereoisomerism*. **Stereoisomers** are molecules with the same arrangement of atoms *but different orientations of groups in space*. *Optical isomerism* is one type of stereoisomerism: *when two objects are*

mirror images of each other and cannot be superimposed, they are **optical isomers**, also called *enantiomers*. Your right hand is an optical isomer of your left. Look at your right hand in a mirror: the *image* is identical to your left hand (Figure 15.8). No matter how you twist your arms around, however, your hands cannot lie on top of each other with your palms facing in the same direction and be superimposed.

**Asymmetry and Chirality** Optical isomers are not superimposable because each is *asymmetric*: there is no plane of symmetry that divides the molecule (or your hand) into two identical parts. An asymmetric molecule is called **chiral** (Greek *cheir*, “hand”). Typically, an organic molecule is *chiral if it contains a carbon atom that is bonded to four different groups*. This C atom is called a *chiral center*, or an asymmetric carbon. In 3-methylhexane, for example, C-3 is a chiral center, because it is bonded to four different groups: H—, CH<sub>3</sub>—, CH<sub>3</sub>—CH<sub>2</sub>—, and CH<sub>3</sub>—CH<sub>2</sub>—CH<sub>2</sub>— (Figure 15.9A). Like your two hands, the two forms are mirror images: when two of the groups are superimposed, the other two are opposite each other. The central C atom in the amino acid alanine is also a chiral center (Figure 15.9B).

**Properties of Optical Isomers** Unlike constitutional isomers, which have different physical properties, optical isomers are identical in all but two respects:

1. In their physical properties, *optical isomers differ only in the direction that each isomer rotates the plane of polarized light*. A **polarimeter** is used to measure the angle that the plane is rotated (Figure 15.10). A beam of light consists of waves that oscillate in all planes. A polarizing filter blocks all waves except those in one plane, so the light emerging through the filter is *plane-polarized*. An optical isomer is **optically active** because it rotates the plane of this polarized light. (Liquid crystal displays incorporate polarizing filters and optically active compounds; see Figure 12.44.) The *dextrorotatory* isomer (designated *d* or *+*) rotates the plane of light clockwise; the *levorotatory* isomer (designated *l* or *-*) is the mirror image of the *d* isomer and rotates the plane counterclockwise. An equimolar mixture of the two isomers (called a *racemic mixture*) does not rotate the plane of light because the dextrorotation cancels the levorotation. The *specific rotation* is a characteristic, measurable property of an optical isomer at a certain temperature and concentration and with a particular wavelength of light.

2. In their chemical properties, *optical isomers differ only in a chiral (asymmetric) chemical environment*, one that distinguishes “right-handed” from “left-handed” molecules. As an analogy, your right hand fits well in your right glove but not in your left glove. Typically, one isomer of an optically active reactant is added to a mixture

**Figure 15.8** An analogy for optical isomers.

**Figure 15.9** Two chiral molecules.

**Figure 15.10** The rotation of plane-polarized light by an optically active substance.

**Figure 15.11** The binding site of an enzyme.

of optical isomers of another compound. The products of the reaction have different properties and can be separated.

**The Role of Optical Isomerism in Organisms and Medicines** Optical isomerism plays a vital role in living cells. Nearly all carbohydrates and amino acids are optically active, but only one of the isomers is biologically usable. For example, *d*-glucose is metabolized for energy, but *l*-glucose is not, and is excreted unused. Similarly, *l*-alanine is incorporated naturally into proteins, but *d*-alanine is not. An organism can utilize only one of a pair of optical isomers because of its enzymes (Section 16.7). Enzymes are proteins that speed virtually every reaction in a living cell by binding to the reactants and influencing bond breakage and formation. An enzyme distinguishes one optical isomer from another because its binding site is chiral (asymmetric) (Figure 15.11). The shape of one optical isomer fits at the binding site, but the mirror image shape of the other isomer does not fit, so it cannot bind.

Many drugs are chiral molecules. One optical isomer has certain biological activity, and the other has either a different type of activity or none at all. Naproxen (*see margin*), a pain reliever and anti-inflammatory agent, is an example: one isomer is active as an anti-arthritis agent, and the other is a potent liver toxin that must be removed from the mixture during manufacture. The notorious drug thalidomide is another example: one optical isomer is active against depression, whereas the other causes fetal mutations and deaths. Tragically, this drug was sold in the 1950s as the racemic mixture and caused limb malformations in many newborns whose mothers had it prescribed to relieve “morning sickness” during pregnancy.

## Alkenes: Hydrocarbons with Double Bonds

A hydrocarbon that contains at least one C=C bond is called an **alkene**, and has the following features:

- With two H atoms removed to make the double bond, alkenes have the general formula  $C_nH_{2n}$ . The five carbon alkene ( $n = 5$ ), for example, has a formula of  $C_5H_{(2 \times 5)}$ , or  $C_5H_{10}$ .
- The double-bonded C atoms are  $sp^2$  hybridized.
- Because their carbon atoms are bonded to fewer than the maximum of four atoms each, alkenes are considered **unsaturated hydrocarbons**.

Alkene names differ from those of alkanes in two respects:

1. The main chain (root) *must* contain both C atoms of the double bond, even if it is not the longest chain. The chain is numbered from the end *closer* to the C=C bond, and the position of the bond is indicated by the number of the *first* C atom in it.
2. The suffix for alkenes is *-ene*.

For example, the three four-C alkenes ( $C_4H_8$ ), two unbranched and one branched, whose structures were drawn in Sample Problem 15.1b, are named as follows:

(As you’ll see next, there are two different 2-butenes due to another type of stereoisomerism.)

There are two major structural differences between alkanes and alkenes.

- Alkanes have a *tetrahedral* geometry (bond angles of  $\sim 109.5^\circ$ ) around each C atom, whereas the double-bonded C atoms in alkenes are *trigonal planar* ( $\sim 120^\circ$ ).
- The C—C bond *allows* rotation of bonded groups, so the atoms in an alkane continually change their relative positions; in contrast, the  $\pi$  bond of the alkene C=C bond *restricts* rotation, so the relative positions of the atoms attached to the double bond are fixed (see Section 11.2).

Table 15.4

The Geometric Isomers of 2-Butene

Systematic Name	Condensed and Skeleton Formulas	Space-Filling Model	Density (g/mL)	Boiling Point (°C)
<i>cis</i> -2-Butene			0.621	3.7
<i>trans</i> -2-Butene			0.604	0.9

### Restricted Rotation and Geometric (*cis-trans*) Isomerism

This rotational restriction of the  $\pi$  bond in the  $C=C$  bond leads to another type of stereoisomerism. **Geometric isomers** (also called *cis-trans isomers*) have different orientations of groups around a double bond (or similar structural feature). Table 15.4 shows the two geometric isomers of 2-butene (see Comment, Sample Problem 15.1):

- One isomer, *cis*-2-butene, has the  $CH_3$  groups on the *same* side of the  $C=C$  bond; in general, the *cis* isomer has the *larger portions of the main chain* (in this case, two  $CH_3$  groups) *on the same side* of the double bond.
- The other isomer, *trans*-2-butene, has the  $CH_3$  on *opposite* sides of the  $C=C$  bond; the *trans* isomer generally has the *larger portions of the main chain on the opposite sides* of the double bond.

For a molecule to have geometric isomers, *each C atom in the  $C=C$  bond must also be bonded to two different groups.*

Like structural isomers, geometric isomers have different physical properties. Note in Table 15.4 that the two 2-butenes differ in molecular shape *and* physical properties. The *cis* isomer has a bend in the chain that the *trans* isomer lacks. In Chapters 10 and 12, you saw how such a difference affects molecular polarity and physical properties, which arise from differing strengths of intermolecular attractions.

**Geometric Isomers and the Chemistry of Vision** Differences in geometric isomers have profound effects in biological systems. For example, the first step in the sequence that allows us to see relies on the different shapes of two geometric isomers. *Retinal*, a 20-C compound consisting of a 15-C chain, including a ring, with five  $C=C$  bonds and five 1-C branches, is part of the molecule responsible for receiving light energy that is then converted to electrical signals transmitted to the brain. There are two biologically occurring isomers of retinal:

- The all-*trans* isomer has a *trans* orientation around all five double bonds and is elongated.
- The 11-*cis* isomer has a *cis* orientation around the  $C=C$  bond between C-11 and C-12 and, thus, is bent.

Certain cells of the retina are densely packed with *rhodopsin*, a large molecule consisting of a protein covalently bonded to 11-*cis* retinal. The initial chemical event in vision occurs when rhodopsin absorbs a photon of visible light. The energy range of visible photons (165–293 kJ/mol) encompasses the energy needed to break a  $C=C$   $\pi$  bond (about 250 kJ/mol). Within a few millionths of a second after rhodopsin absorbs a photon, the 11-*cis*  $\pi$  bond of retinal breaks, the intact  $\sigma$  bond between C-11 and C-12 rotates, and the  $\pi$  bond re-forms to produce all-*trans* retinal (Figure 15.12, *next page*).

This rapid, and quite sizeable, change in retinal's shape causes the attached protein to change its shape as well, triggering a flow of ions into the retina's cells and initiating electrical impulses, which the optic nerve conducts to the brain. Meanwhile, the free all-*trans* retinal diffuses away from the protein and is changed back to the

**Figure 15.12** The initial chemical event in vision and the change in the shape of retinal.

*cis* form, which then binds to the protein portion again. Because of the speed and efficiency with which light causes such a large structural change in retinal, evolutionary selection has made it the photon absorber in organisms as different as purple bacteria, mollusks, insects, and vertebrates.

### Alkynes: Hydrocarbons with Triple Bonds

Hydrocarbons that contain at least one  $\text{C}\equiv\text{C}$  bond are called **alkynes**, with the following features:

- Because they have two H atoms fewer than alkenes, their general formula is  $\text{C}_n\text{H}_{2n-2}$ . The alkyne with five carbon atoms has the formula  $\text{C}_5\text{H}_{[(2\times 5)-2]}$ , or  $\text{C}_5\text{H}_8$ .
- A carbon involved in a  $\text{C}\equiv\text{C}$  bond can bond to only one other atom, so the geometry around each C atom is linear ( $180^\circ$ ): each C is *sp* hybridized.
- Alkynes are named in the same way as alkenes, except that the suffix is *-yne*.

Because of their localized  $\pi$  electrons,  $\text{C}=\text{C}$  and  $\text{C}\equiv\text{C}$  bonds are electron rich and act as functional groups. Thus, alkenes and alkynes are much more reactive than alkanes, as we'll discuss in Section 15.4.

#### SAMPLE PROBLEM 15.2

#### Naming Hydrocarbons and Understanding Chirality and Geometric Isomerism

**Problem** Give the systematic name for each of the following, identify the chiral center in part (d), and draw two geometric isomers for the alkene in part (e):

**Plan** For (a) to (c), we refer to Table 15.2. We first name the longest chain (*root-*) and add the suffix *-ane* because there are only single bonds. Then we find the *lowest* branch numbers by counting C atoms from the end *closer* to a branch. Finally, we name each branch (*root-* + *-yl*) and put these names alphabetically before the root name. For (c), we add *cyclo-* before the root. For (d) and (e), we number the longest chain that *includes* the multiple bond starting at the end closer to it. For (d), the chiral center is the C atom bonded to four different groups. In (e), the *cis* isomer has larger groups on the same side of the double bond, and the *trans* isomer has them on opposite sides.

## Solution

2,2-dimethylbutane

When a type of branch appears more than once, we group the branch numbers and indicate the number of branches with a prefix, as in 2,2-dimethyl.

3,4-dimethylhexane

In this case, we can number the chain from either end because the branches are the same and are attached to the two central C atoms.

1-ethyl-2-methylcyclopentane

We number the ring C atoms so that a branch is attached to C-1.

3-methyl-1-pentene

trans-2,3-dimethyl-3-hexene

**Check** A good check (and excellent practice) is to reverse the process by drawing structures for the names to see if you come up with the structures given in the problem.

**Comment 1.** In (b), C-3 and C-4 are chiral centers, as are C-1 and C-2 in (c). However, in (b) the molecule is not chiral: it has a plane of symmetry between C-3 and C-4, so each half of the molecule rotates light in opposite directions. **2.** Avoid these common mistakes: In (b), 2-ethyl-3-methylpentane would be wrong: the longest chain is *hexane*. In (c), 1-methyl-2-ethylcyclopentane would be wrong: the branch names should appear *alphabetically*.

## FOLLOW-UP PROBLEMS

**15.2A** Give the systematic name for each of the following, name the geometric isomer in (c), and identify the chiral centers in part (d):

**15.2B** Draw condensed formulas for the following compounds: (a) 3-ethyl-3-methyloctane; (b) 1-ethyl-3-propylcyclohexane (also draw a carbon-skeleton formula for this compound); (c) 3,3-diethyl-1-hexyne; (d) *trans*-3-methyl-3-heptene.

**SOME SIMILAR PROBLEMS** 15.19–15.30

## Aromatic Hydrocarbons: Cyclic Molecules with Delocalized $\pi$ Electrons

Unlike most cycloalkanes, **aromatic hydrocarbons** are planar molecules, usually with one or more rings of six C atoms, and are often drawn with alternating single and double bonds. As you learned for benzene (Section 10.1), however, all the ring bonds are identical, with values of length and strength *between* those of a C—C and a C=C bond. To indicate this, benzene is also shown as a resonance hybrid, with a circle (or dashed circle) representing the delocalized character of the  $\pi$  electrons (Figure 15.13A). An orbital picture shows the two lobes of the delocalized  $\pi$  cloud above and below the hexagonal plane of the  $\sigma$ -bonded C atoms (Figure 15.13B, *next page*).

The systematic naming of aromatic compounds in which benzene is the main structure is straightforward, because attached groups, or *substituents*, are named as prefixes. However, many common names are still in use. For example, benzene with one methyl group attached is systematically named *methylbenzene* but is better known

**Figure 15.13** Representations of benzene.

by its common name, *toluene*. With only one substituent present, as in toluene, we do not number the ring C atoms; when two or more groups are attached, however, we number in such a way that one of the groups is attached to ring C-1:

In common names, the positions of two groups are indicated by *o*- (ortho) for groups on adjacent ring C atoms, *m*- (meta) for groups separated by one ring C atom, and *p*- (para) for groups on opposite ring C atoms. The dimethylbenzenes (commonly known as *xlenes*) are important solvents and feedstocks for polyester fibers and dyes. Benzene and many other aromatic hydrocarbons have been shown to have carcinogenic (cancer-causing) activity.

The number of isomers increases with more than two attached groups. For example, there are six isomers for a compound with one methyl and three nitro ( $-\text{NO}_2$ ) groups attached to a benzene ring; the explosive TNT is one of the isomers (*see margin*).

One of the most important methods for determining the structures of organic molecules is discussed in the upcoming Tools of the Laboratory essay.

## Variations on a Theme: Catenated Inorganic Hydrides

In brief discussions throughout this chapter, called Variations on a Theme, we examine similarities between organic and inorganic compounds. Although no other element has as many different hydrides as carbon, catenated hydrides occur for several other elements, and many ring, chain, and cage structures are known.

- *Boranes*. One such group of inorganic compounds is the boron hydrides, or boranes (Section 14.5). Although their varied shapes rival those of the hydrocarbons, the weakness of their unusual bridge bonds renders most of them thermally and chemically unstable.
- *Silanes*. An obvious structural similarity exists between alkanes and the silicon hydrides, or silanes. Silanes even have an analogous general formula ( $\text{Si}_n\text{H}_{2n+2}$ ). Branched silanes are known, but no cyclic or unsaturated (containing an  $\text{Si}=\text{Si}$  bond) compounds had been prepared until very recently. Unlike alkanes, silanes are unstable thermally and ignite spontaneously in air.
- *Polysulfanes*. Sulfur's ability to catenate is second only to carbon's, and many chains and rings occur among its allotropes (Section 14.8). A number of sulfur hydrides, or polysulfanes, are known. However, these molecules are unbranched chains with H atoms only at the ends ( $\text{H}-\text{S}_n-\text{H}$ ). Like the silanes, the polysulfanes are oxidized easily and decompose readily, yielding sulfur's only stable hydride,  $\text{H}_2\text{S}$ , and its most stable allotrope, cyclo- $\text{S}_8$ .

In addition to mass spectrometry (Chapter 2) and infrared (IR) spectroscopy (Chapter 9), one of the most useful tools for analyzing organic and biochemical structures is **nuclear magnetic resonance (NMR) spectroscopy**, which measures the molecular environments of certain nuclei in a molecule.

Like electrons, several types of nuclei, such as  $^{13}\text{C}$ ,  $^{19}\text{F}$ ,  $^{31}\text{P}$ , and  $^1\text{H}$ , act as if they spin in either of two directions, each of which creates a tiny magnetic field. In this discussion, we focus primarily on  $^1\text{H}$ -NMR spectroscopy, which measures changes in the nuclei of the most common isotope of hydrogen. Oriented randomly, the magnetic fields of all the  $^1\text{H}$  nuclei in a sample of compound, when placed in a strong external magnetic field ( $B_0$ ), become aligned either *with* the external field (parallel) or *against* it (antiparallel). Most nuclei adopt the parallel orientation, which is slightly lower in energy. The energy difference ( $\Delta E$ ) between the two energy states (spin states) lies in the radio-frequency (rf) region of the electromagnetic spectrum (Figure B15.1).

When an  $^1\text{H}$  (blue arrow) in the lower energy (parallel) spin state absorbs a photon in the radio-frequency region with an energy equal to  $\Delta E$ , it “flips,” in a process called *resonance*, to the higher energy (antiparallel) spin state. The system then re-emits that energy, which is detected by the rf receiver of the  $^1\text{H}$ -NMR spectrometer. The  $\Delta E$  between the two states depends on the *actual* magnetic field acting on each  $^1\text{H}$  nucleus, which is affected by the tiny magnetic fields of the *electrons* of atoms adjacent to that nucleus. Thus, the  $\Delta E$  required for resonance of each  $^1\text{H}$  nucleus depends on its specific molecular environment—the C atoms, electronegative atoms, multiple bonds, and aromatic rings around it.  $^1\text{H}$  nuclei in different molecular environments produce different peaks in the  $^1\text{H}$ -NMR spectrum.

An  $^1\text{H}$ -NMR spectrum, which is unique for each compound, is a series of peaks that represents the resonance as a function of the changing magnetic field. The *chemical shift* of the  $^1\text{H}$  nuclei in a given environment is where a peak appears. Chemical shifts are shown relative to that of an added standard, tetramethylsilane [( $\text{CH}_3$ ) $_4\text{Si}$ , or TMS]. TMS has 12  $^1\text{H}$  nuclei bonded to four C atoms that are bonded to one Si atom in a tetrahedral arrangement, so all 12 are in identical environments and produce only one peak.

Figure B15.2 shows the  $^1\text{H}$ -NMR spectrum of acetone. The six  $^1\text{H}$  nuclei of acetone have identical environments: all six are bonded to two C atoms that are each bonded to the C atom involved in the C=O bond. So one peak is produced, but at a different position from the TMS peak. The spectrum of dimethoxymethane in Figure B15.3 shows *two* peaks in addition to the TMS peak since the  $^1\text{H}$  nuclei have two different environments. The taller peak is due to the six  $^1\text{H}$  nuclei in the two  $\text{CH}_3$  groups, and the shorter peak is due to the two  $^1\text{H}$  nuclei in the  $\text{CH}_2$  group. The area under each peak (given as a number of chart-paper grid spaces) is proportional to *the number of  $^1\text{H}$  nuclei in a given environment*. Note that the area ratio is  $20.3/6.8 \approx 3/1$ , the same as the ratio of six nuclei in the  $\text{CH}_3$  groups to two in the  $\text{CH}_2$  group. Thus, by analyzing the chemical shifts and peak areas, the chemist learns the type and number of hydrogen atoms in the compound.

Figure B15.1 The basis of  $^1\text{H}$  spin resonance.

Figure B15.2 The  $^1\text{H}$ -NMR spectrum of acetone.

Figure B15.3 The  $^1\text{H}$ -NMR spectrum of dimethoxymethane.

(continued)

NMR has many applications in biochemistry and medicine. Applying the principle to the imaging of organs and other body parts is known as *computer-aided magnetic resonance imaging*, or *MRI*. For example, an MRI scan of a person's head (Figure B15.4) can reveal a brain tumor by mapping levels of metabolic activity in different regions of the brain.

**Figure B15.4** An MRI scan showing a brain tumor.

### Problems

**B15.1** How many peaks appear in the NMR spectrum of each isomer of  $C_4H_{10}$  and of  $C_5H_{12}$  shown in Table 15.3?

**B15.2** Radio-frequency radiation is used in NMR since  $\Delta E$ , the energy difference between the two spin states of the  $^1H$  nucleus, is very small. Calculate the  $\Delta E$  (in J/mol) that corresponds to a frequency of 200. MHz.

**B15.3** Consider three isomers of  $C_4H_8Br_2$ :

**A**

**B**

**C**

Which of these isomers is characterized by a  $^1H$ -NMR spectrum that consists of two peaks with a 3/1 area ratio?

## › Summary of Section 15.2

- › Hydrocarbons contain only C and H atoms, so their physical properties depend on the strength of their dispersion forces.
- › Names of organic compounds consist of a root for the longest chain, a prefix for any attached group, and a suffix for the type of compound.
- › Alkanes ( $C_nH_{2n+2}$ ) have only single bonds. Cycloalkanes ( $C_nH_{2n}$ ) have ring structures that are typically nonplanar. Alkenes ( $C_nH_{2n}$ ) have at least one  $C=C$  bond. Alkynes ( $C_nH_{2n-2}$ ) have at least one  $C\equiv C$  bond. Aromatic hydrocarbons have at least one planar ring with delocalized  $\pi$  electrons.
- › Isomers are compounds with the same molecular formula but different properties.
- › Constitutional (structural) isomers have different arrangements of atoms.
- › Stereoisomers (optical and geometric) have the same arrangement of atoms, but their atoms are oriented differently in space. Optical isomers cannot be superimposed on each other because they are asymmetric, with four different groups bonded to the C that is the chiral center. They have identical physical and chemical properties except in their rotation of plane-polarized light, their reactivity with chiral reactants, and their biological activity. Geometric (*cis-trans*) isomers have groups oriented differently around a  $C=C$  bond, which restricts rotation.
- › Light converts a *cis* isomer of retinal to the all-*trans* form, which initiates the process of vision.
- › Boron, silicon, and sulfur also form catenated hydrides, but these are unstable.
- ›  $^1H$ -NMR spectroscopy indicates the relative numbers of H atoms in the various environments within an organic molecule.

## 15.3 SOME IMPORTANT CLASSES OF ORGANIC REACTIONS

In Chapter 4, we classified chemical reactions based on the chemical process involved (precipitation, acid-base, or redox) and then briefly included a classification based on the number of reactants and products (combination, decomposition, or displacement). We take a similar approach here with organic reactions.

To depict reactions more generally, it's common practice to use R— to signify a nonreacting organic group attached to one of the atoms; you can usually picture R— as an **alkyl group**, a saturated hydrocarbon chain with one bond available. Thus, R—CH<sub>2</sub>—Br has an alkyl group attached to a CH<sub>2</sub> group bonded to a Br atom; R—CH=CH<sub>2</sub> is an alkene with an alkyl group attached to one of the carbons in the double bond; and so forth. (Often, when more than one R group is present, we write R, R', R'', and so forth, to indicate that these groups may be different.)

### Types of Organic Reactions

Three important organic reaction types are *addition*, *elimination*, and *substitution* reactions, which can be identified by comparing the *number of bonds to C* in reactants and products.

**Addition Reactions** An **addition reaction** occurs when an unsaturated reactant becomes a saturated product:

Note the C atoms are bonded to *more* atoms in the product than in the reactant.

The C=C and C≡C bonds and the C=O bond commonly undergo addition reactions. In each case, the π bond breaks, leaving the σ bond intact. In the product, the two C atoms (or C and O) form two additional σ bonds. Let's examine the standard enthalpy of reaction ( $\Delta H_{\text{rxn}}^\circ$ ) for a typical addition reaction to see why these reactions occur. Consider the reaction between ethene (common name, ethylene) and HCl:

Reactants (bonds broken)	Product (bonds formed)
1 C=C = 614 kJ	1 C—C = -347 kJ
4 C—H = 1652 kJ	5 C—H = -2065 kJ
1 H—Cl = 427 kJ	1 C—Cl = -339 kJ
<b>Total = 2693 kJ</b>	<b>Total = -2751 kJ</b>

$$\Delta H_{\text{rxn}}^\circ = \Sigma \Delta H_{\text{bonds broken}}^\circ + \Sigma \Delta H_{\text{bonds formed}}^\circ = 2693 \text{ kJ} + (-2751 \text{ kJ}) = -58 \text{ kJ}$$

The reaction is exothermic. By looking at the *net* change in bonds, we see that the driving force for many additions is the formation of two σ bonds (in this case, C—H and C—Cl) from one σ bond (in this case, H—Cl) and one relatively weak π bond. An addition reaction is the basis of a color test for the presence of C=C bonds (Figure 15.14).

**Elimination Reactions** **Elimination reactions** are the opposite of addition reactions. They occur when a saturated reactant becomes an unsaturated product:

**Figure 15.14** A color test for C=C bonds. **A**, Br<sub>2</sub> (in pipet) reacts with a compound that has a C=C bond (in beaker), and its orange-brown color disappears:

**B**, Here the compound in the beaker has no C=C bond, so the Br<sub>2</sub> does not react. Source: © McGraw-Hill Education/Richard Megna, photographer

Note that the C atoms are bonded to *fewer* atoms in the product than in the reactant. A pair of halogen atoms, an H atom and a halogen atom, or an H atom and an —OH group are typically eliminated, but C atoms are not. Thus, the driving force for many elimination reactions is the formation of a small, stable molecule, such as HCl(g) or H<sub>2</sub>O, which increases the entropy of the system (Section 13.3):

**Substitution Reactions** A **substitution reaction** occurs when an atom (or group) in one reactant substitutes for one attached to a carbon in the other reactant:

Note that the C atom is bonded to the *same number* of atoms in the product as in the reactant. The C atom may be saturated or unsaturated, and X and Y can be many different atoms, but generally *not* C. The main flavor ingredient in banana oil, for instance, forms through a substitution reaction; note that the O substitutes for the Cl:

### SAMPLE PROBLEM 15.3

### Recognizing the Type of Organic Reaction

**Problem** State whether each reaction is an addition, elimination, or substitution:

**Plan** We determine the type of reaction by looking for any change in the number of atoms bonded to C:

- More atoms bonded to C is an *addition*.
- Fewer atoms bonded to C is an *elimination*.
- Same number of atoms bonded to C is a *substitution*.

**Solution** (a) **Elimination:** two bonds in the reactant, C—H and C—Br, are absent in the product, so fewer atoms are bonded to C.

(b) **Addition:** two more C—H bonds have formed in the product, so more atoms are bonded to C.

(c) **Substitution:** the reactant C—Br bond becomes a C—O bond in the product, so the same number of atoms are bonded to C.

## FOLLOW-UP PROBLEMS

**15.3A** State whether each reaction is an addition, elimination, or substitution:

**15.3B** Write a balanced equation for each of the following:

- (a) An addition reaction between 2-butene and  $\text{Cl}_2$   
 (b) A substitution reaction between  $\text{CH}_3\text{—CH}_2\text{—CH}_2\text{—Br}$  and  $\text{OH}^-$   
 (c) The elimination of  $\text{H}_2\text{O}$  from  $(\text{CH}_3)_3\text{C—OH}$

**SOME SIMILAR PROBLEMS** 15.40–15.43

## The Redox Process in Organic Reactions

An important process in many organic reactions is *oxidation-reduction*. Even though a redox reaction always involves both an oxidation and a reduction, organic chemists typically *focus on the organic reactant only*. Instead of monitoring the change in oxidation numbers of the various C atoms, organic chemists usually note the movement of electron density around a C atom by counting the number of bonds to more electronegative atoms (usually O) or to less electronegative atoms (usually H). A more electronegative atom takes some electron density from the C, whereas a less electronegative atom gives some electron density to the C. Therefore,

- When a C atom in the organic reactant forms more bonds to O or fewer bonds to H, thus losing some electron density, the reactant is oxidized, and the reaction is called an *oxidation*.
- When a C atom in the organic reactant forms fewer bonds to O or more bonds to H, thus gaining some electron density, the reactant is reduced, and the reaction is called a *reduction*.

The most dramatic redox reactions are combustion reactions. Virtually all organic compounds contain C and H atoms and burn in excess  $\text{O}_2$  to form  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . For ethane, the reaction is

Obviously, when ethane is converted to  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , each of its C atoms has more bonds to O and fewer bonds to H. Thus, ethane is oxidized, and this reaction is referred to as an *oxidation*, even though  $\text{O}_2$  is reduced as well.

Most oxidations do not involve a breakup of the entire molecule, however. When 2-propanol reacts with potassium dichromate in acidic solution (a common oxidizing agent in organic reactions), it forms 2-propanone (acetone):

Note that C-2 has one fewer bond to H and one more bond to O in 2-propanone than it does in 2-propanol. Thus, 2-propanol is oxidized, so this is an *oxidation*. Don't forget, however, that the dichromate ion is reduced at the same time:

The reaction between  $\text{H}_2$  and an alkene is both an addition and a *reduction*:

Note that each C has more bonds to H in ethane than it has in ethene, so the ethene is reduced. The  $H_2$  is oxidized in the process, and the palladium shown over the arrow acts as a catalyst to speed up the reaction. (We discuss catalysts in Section 16.7.)

### › Summary of Section 15.3

- › In an addition reaction, a  $\pi$  bond breaks, and the two C atoms (or one C and one O) are bonded to more atoms in the product.
- › In an elimination reaction, a  $\pi$  bond forms, with the two C atoms bonded to fewer atoms in the product.
- › In a substitution reaction, one atom bonded to C is replaced by another, but the total number of atoms bonded to the C does not change.
- › In an organic redox reaction, the organic reactant is oxidized if at least one of its C atoms forms more bonds to O atoms (or fewer bonds to H atoms), and it is reduced if one of its C atoms forms more bonds to H (or fewer bonds to O).

#### Methanol (methyl alcohol)

Byproduct in coal gasification; de-icing agent; gasoline substitute; precursor of organic compounds

#### 1,2-Ethanediol (ethylene glycol)

Main component of auto antifreeze

#### Serine

Amino acid found in most proteins

## 15.4 PROPERTIES AND REACTIVITIES OF COMMON FUNCTIONAL GROUPS

A central organizing principle of organic reactions is that *the distribution of electron density in a functional group is a key to the reactivity of the compound*. The electron density can be high, as in the  $C=C$  and  $C\equiv C$  bonds, or it can be low at one end of a bond and high at the other, as in the  $C-Cl$  and  $C-O$  bonds. Such electron-rich or polar bonds enhance the opposite charge in a polar bond of the other reactant. As a result, the reactants attract each other and begin a sequence of bond-forming and bond-breaking steps that lead to a product. Thus, *the intermolecular forces that affect physical properties and solubility also affect reactivity*. Table 15.5 lists some of the important functional groups in organic compounds.

When we classify functional groups by bond order, they follow certain patterns of reactivity:

- Functional groups with only single bonds undergo elimination or substitution.
- Functional groups with double or triple bonds undergo addition.
- Functional groups with both single and double bonds undergo substitution.

In this section, we see how to name compounds that contain each functional group, examine some of their properties, and summarize their common reactions.

### Functional Groups with Only Single Bonds

The most common functional groups with only single bonds are alcohols, haloalkanes, and amines.

**Alcohols** The **alcohol** functional group consists of a carbon bonded to an OH group,  $\begin{array}{c} | \\ -C-\ddot{O}-H \\ | \end{array}$ , and the general formula of an alcohol is  $R-OH$ . Alcohols are

named by dropping the final *-e* from the parent hydrocarbon name and adding the suffix *-ol*. Thus, the two-carbon alcohol is ethanol (ethan- + *-ol*). The common name of an alcohol is the hydrocarbon *root-* + *-yl*, followed by “alcohol”; thus, the common name of ethanol is ethyl alcohol. (This substance, obtained from fermented grain, has been consumed by people as an intoxicant in beverages since ancient times; today, it is recognized as the most abused drug in the world.) Alcohols are common organic reactants, and the functional group occurs in many biomolecules, including carbohydrates, sterols, and some amino acids. Figure 15.15 shows the names, structures, and uses of some important compounds that contain the alcohol functional group.

#### Cholesterol

Major sterol in animals; essential for cell membranes; precursor of steroid hormones

**Figure 15.15** Some molecules with the alcohol functional group.

Table 15.5

## Important Functional Groups in Organic Compounds

Functional Group	Compound Type	Prefix or Suffix of Name	Example		Systematic Name (Common Name)
			Lewis Structure	Ball-and-Stick Model	
	alkene	-ene			ethene (ethylene)
$\text{—C}\equiv\text{C—}$	alkyne	-yne	$\text{H—C}\equiv\text{C—H}$		ethyne (acetylene)
	alcohol	-ol			methanol (methyl alcohol)
 (X = halogen)	haloalkane	halo-			chloromethane (methyl chloride)
	amine	-amine			ethanamine (ethylamine)
	aldehyde	-al			ethanal (acetaldehyde)
	ketone	-one			2-propanone (acetone)
	carboxylic acid	-oic acid			ethanoic acid (acetic acid)
	ester	-oate			methyl ethanoate (methyl acetate)
	amide	-amide			ethanamide (acetamide)
$\text{—C}\equiv\text{N:}$	nitrile	-nitrile			ethanenitrile (acetonitrile, methyl cyanide)

The physical properties of the smaller alcohols are similar to those of water. They have high melting and boiling points as a result of hydrogen bonding, and they dissolve polar molecules and some salts.

Alcohols undergo elimination and substitution reactions:

- *Elimination* of H and OH, called *dehydration*, requires acid and forms an alkene:

- *Elimination* of two H atoms is an *oxidation* that requires an inorganic oxidizing agent, such as potassium dichromate ( $\text{K}_2\text{Cr}_2\text{O}_7$ ) in aqueous  $\text{H}_2\text{SO}_4$ . The product has a  $\text{C}=\text{O}$  group:

- Alcohols with an OH group at the end of the chain ( $\text{R}-\text{CH}_2-\text{OH}$ ) can be oxidized further to acids (but this step is *not* an elimination). Wine turns sour, for example, when the ethanol in contact with air is oxidized to acetic acid:

- *Substitution* yields products with other single-bonded functional groups. Reactions of hydrohalic acids with many alcohols give haloalkanes:

As you'll see below, the C atom undergoing the change in a substitution is bonded to a more electronegative element, which makes it partially positive and, thus, a target for a negatively charged or electron-rich group of an incoming reactant.

**Haloalkanes** A halogen atom (X) bonded to a carbon forms the **haloalkane** functional group,  $\begin{array}{c} | \\ \text{C}-\ddot{\text{X}}: \\ | \end{array}$ , found in compounds with the general formula  $\text{R}-\text{X}$ . Haloalkanes (common name, **alkyl halides**) are named by identifying the halogen using a prefix on the hydrocarbon name and numbering the C atom to which the halogen is attached, as in **bromomethane**, **2-chloropropane**, or **1,3-diiodohexane**.

Like alcohols, haloalkanes undergo substitution and elimination reactions.

- Just as many alcohols undergo substitution to form alkyl halides when treated with halide ions in acid, many haloalkanes undergo substitution in base to form alcohols. For example,  $\text{OH}^-$  attacks the positive C end of the  $\text{C}-\text{X}$  bond and displaces  $\text{X}^-$ :

Substitutions by groups such as  $-\text{CN}$ ,  $-\text{SH}$ ,  $-\text{OR}$ , and  $-\text{NH}_2$  allow chemists to convert haloalkanes to a host of other types of compounds.

- Just as addition of  $\text{HX}$  to an alkene produces haloalkanes, elimination of  $\text{HX}$  from a haloalkane by reaction with a strong base, such as potassium ethoxide, produces an alkene:

Haloalkanes have many important uses, but some, like the chlorofluorocarbons, cause serious environmental problems (Chapter 16 Chemical Connections). Also, some halogenated *aromatic* hydrocarbons (*aryl* halides) are carcinogenic in mammals, have severe neurological effects in humans, and, to make matters worse, are very stable in the environment. For example, the polychlorinated biphenyls (PCBs) (Figure 15.16), used as insulating fluids in electrical transformers, have accumulated for decades in rivers and lakes and have been incorporated into the food chain. PCBs in natural waters pose health risks and present an enormous cleanup problem.

**Amines** The **amine** functional group is  $\text{—}\overset{\text{R}}{\underset{\text{R}}{\text{C}}}\text{—}\ddot{\text{N}}\text{—}$ . Chemists classify amines as derivatives of ammonia, with R groups in place of one or more of the H atoms in  $\text{NH}_3$ :

- *Primary* ( $1^\circ$ ) amines are  $\text{RNH}_2$ .
- *Secondary* ( $2^\circ$ ) amines are  $\text{R}_2\text{NH}$ .
- *Tertiary* ( $3^\circ$ ) amines are  $\text{R}_3\text{N}$ .

The R groups in secondary and tertiary amines can be the same or different. Like ammonia, amines have trigonal pyramidal shapes and a lone pair of electrons on a partially negative N atom, which is the key to amine reactivity (Figure 15.17).

Systematic names drop the final *-e* of the alkane and add the suffix *-amine*, as in ethan**amine**. However, there is still wide usage of common names, in which the suffix *-amine* follows the name of the alkyl group; thus, methylamine has one methyl group attached to N, diethylamine has two ethyl groups attached, and so forth. Figure 15.18 shows that the amine functional group occurs in many biomolecules.

Primary and secondary amines can form H bonds, so they have higher melting and boiling points than hydrocarbons and alkyl halides of similar molar mass. For example, dimethylamine ( $\mathcal{M} = 45.09$  g/mol) boils  $45^\circ\text{C}$  higher than ethyl fluoride ( $\mathcal{M} = 48.06$  g/mol). Trimethylamine has a greater molar mass than dimethylamine, but it melts more than  $20^\circ\text{C}$  *lower* because its N does not have an attached H atom that could participate in H bonding.

**Figure 15.16** A tetrachlorobiphenyl, one of 209 polychlorinated biphenyls (PCBs).

**Figure 15.17** General structures of amines.

**Figure 15.18** Some biomolecules with the amine functional group.

Amines of low molar mass are fishy smelling, water soluble, and weakly basic because of the lone pair on N. The reaction with water proceeds only slightly to the right to reach equilibrium:

The lone pair is also the reason amines undergo substitution reactions: the lone pair attacks the partially positive C in an alkyl halide to displace  $\text{X}^-$  and form a larger amine:

(Two molecules of amine are needed: one attacks the chloroethane, and the other binds the released  $\text{H}^+$  to prevent it from remaining on the diethylamine product.)

### SAMPLE PROBLEM 15.4

### Predicting the Reactions of Alcohols, Alkyl Halides, and Amines

**Problem** Determine the reaction type and the organic product(s) for each reaction:

**Plan** We first determine the functional group(s) of the organic reactant(s) and then examine any inorganic reactant(s) to decide on the reaction type, keeping in mind that, in general, these functional groups undergo substitution or elimination. (a) The reactant is a haloalkane, so the  $\text{OH}^-$  of the inorganic base  $\text{NaOH}$  substitutes for  $\text{I}^-$ . (b) The reactants are an amine and an alkyl halide, so the N of the amine substitutes for the Br. (c) The organic reactant is an alcohol, the inorganic reactants form a strong oxidizing agent, and the alcohol group undergoes elimination to form a  $\text{C}=\text{O}$  group.

**Solution** (a) **Substitution:** The product is  $\text{CH}_3-\text{CH}_2-\text{CH}_2-\text{OH} + \text{NaI}$

(b) **Substitution:** The products are  $\text{CH}_3-\text{CH}_2-\text{CH}_2-\underset{\text{CH}_2-\text{CH}_3}{\text{NH}} + \text{CH}_3-\text{CH}_2-\text{CH}_2-\overset{+}{\text{N}}\text{H}_3\text{Br}^-$

(c) **Elimination (oxidation):** The product is  $\text{CH}_3-\overset{\text{O}}{\parallel}{\text{C}}-\text{CH}_3$

**Check** The only changes should be at the functional group.

### FOLLOW-UP PROBLEMS

**15.4A** Determine the reaction type and the organic product(s) for each reaction:

**15.4B** Fill in the blank in each reaction. (*Hint:* Examine any inorganic compounds and the organic product to determine the organic reactant.)

**SOME SIMILAR PROBLEMS** 15.65–15.74

### Variations on a Theme: Inorganic Compounds with Single Bonds to O, X, or N

The —OH group occurs frequently in inorganic compounds. All oxoacids contain at least one —OH, usually bonded to a relatively electronegative nonmetal atom, which in most cases is bonded to other O atoms. Oxoacids are acidic in water because these additional O atoms pull electron density from the central nonmetal, which pulls electron density from the O—H bond, releasing an H<sup>+</sup> ion and stabilizing the oxoanion through resonance. Alcohols are *not* acidic in water because they lack the additional O atoms and the electronegative nonmetal.

Halides of nearly every nonmetal are known, and many undergo substitution reactions in base. As in the case of a haloalkane, the process involves an attack on the partially positive central atom by OH<sup>−</sup>:

Thus, haloalkanes undergo the same general reaction as other nonmetal halides, such as BCl<sub>3</sub>, SiF<sub>4</sub>, and PCl<sub>5</sub>.

The bonds between nitrogen and larger nonmetals, such as Si, P, and S, have significant double-bond character, which affects structure and reactivity. For example, (SiH<sub>3</sub>)<sub>3</sub>N, trisilylamine, the Si analog of trimethylamine, is trigonal planar, rather than trigonal pyramidal, because of the formation of a double bond between N and Si. Because the lone pair on N is delocalized in this π bond, trisilylamine is not basic.

### Functional Groups with Double Bonds

The most important functional groups with double bonds are the C=C group of alkenes and the C=O group of aldehydes and ketones. Both appear in many organic and biological molecules. *Their most common reaction type is addition.*

**Alkenes** The C=C bond is the essential portion of the *alkene* functional group,

Although they undergo elimination to alkynes, *alkenes typically undergo addition.* The electron-rich double bond is readily attracted to the partially positive H atoms of hydronium ions and hydrohalic acids, yielding alcohols and alkyl halides, respectively:

**Comparing the Reactivities of Alkenes and Aromatic Compounds** The *localized* unsaturation of alkenes is very different from the *delocalized* unsaturation of aromatic compounds. That is, despite the way we depict its resonance forms, benzene does *not* have double bonds and so, for example, it does not decolorize Br<sub>2</sub> (see Figure 15.14).

In general, aromatic rings are much *less* reactive than alkenes because of their delocalized π electrons. For example, let's compare the enthalpies of reaction for the

Figure 15.19 The stability of benzene.

addition of  $\text{H}_2$ . Hydrogenation of cyclohexene, with one  $\text{C}=\text{C}$  bond, has a  $\Delta H_{\text{rxn}}^\circ$  of  $-120$  kJ/mol. For the imaginary molecule “cyclohexatriene,” that is, the structure with three  $\text{C}=\text{C}$  bonds, the hypothetical  $\Delta H_{\text{rxn}}^\circ$  for hydrogenation would be three times as much, or  $-360$  kJ/mol. Hydrogenation of benzene has a  $\Delta H_{\text{rxn}}^\circ$  of  $-208$  kJ/mol. Thus, the  $\Delta H_{\text{rxn}}^\circ$  for hydrogenation of benzene is 152 kJ/mol *less* than that for “cyclohexatriene.” This energy difference is attributed to the aromatic resonance stabilization of benzene (Figure 15.19).

This extra energy needed to break up the delocalized  $\pi$  system means *addition* reactions with benzene occur rarely. But, benzene does undergo many *substitution* reactions in which the delocalization is retained when an H atom attached to a ring C is replaced by another group:

**Aldehydes and Ketones** The  $\text{C}=\text{O}$  bond, or **carbonyl group**, is one of the most chemically versatile.

- In the **aldehyde** functional group, the carbonyl C is bonded to H (and typically to another C), so it occurs *at the end of a chain*,  $\text{R}-\overset{\text{:O:}}{\parallel}{\text{C}}-\text{H}$ . Aldehyde names drop the final *-e* from the alkane name and add *-al*; thus, the three-C aldehyde is **propanal**.
- In the **ketone** functional group, the carbonyl C is bonded to two other C atoms,

$\text{---}\overset{\text{:O:}}{\parallel}{\text{C}}\text{---}$ , so it occurs *within the chain*. Ketones,  $\text{R}-\overset{\text{O}}{\parallel}{\text{C}}-\text{R}'$ , are named by numbering the carbonyl C, dropping the final *-e* from the alkane name, and adding *-one*. For example, the unbranched, five-C ketone with the carbonyl C as C-2 in the chain is named **2-pentanone**. Figure 15.20 shows some common carbonyl compounds.

Aldehydes and ketones are formed by the oxidation of alcohols:

**Methanal (formaldehyde)**

Used to make resins in plywood, dishware, counter-tops; biological preservative

**Ethanal (acetaldehyde)**

Narcotic product of ethanol metabolism; used to make perfumes, flavors, plastics, other chemicals

**Benzaldehyde**

Artificial almond flavoring

**2-Propanone (acetone)**

Solvent for fat, rubber, plastic, varnish, lacquer; chemical feedstock

**2-Butanone (methyl ethyl ketone)**

Important solvent

Figure 15.20 Some common aldehydes and ketones.

Conversely, as a result of their unsaturation, carbonyl compounds can undergo *addition* and be reduced to alcohols:

Like the C=C bond, the C=O bond is *electron rich*; unlike the C=C bond, it is *highly polar* ( $\Delta EN = 1.0$ ). Figure 15.21 depicts this polarity with an orbital contour model (Figure 15.21A) and a charged resonance form (Figure 15.21B).

As a result of the bond polarity, addition often occurs with an electron-rich group bonding to the carbonyl C and an electron-poor group bonding to the carbonyl O. **Organometallic compounds**, which have a metal atom (usually Li or Mg) attached to an R group through a polar covalent bond, take part in this type of reaction. In a two-step sequence, they convert carbonyl compounds to alcohols with *different carbon skeletons*:

In the following example, the electron-rich C bonded to Li in ethyllithium,  $\text{CH}_3\text{CH}_2\text{Li}$ , attacks the electron-poor carbonyl C of 2-propanone, adding the ethyl group to that C; at the same time, the Li adds to the carbonyl O. Treating the mixture with water forms the C—OH group in the product, 2-methyl-2-butanol:

Note that the product skeleton combines the two reactant skeletons. The field of *organic synthesis* often employs organometallic compounds to create new compounds with different skeletons.

### SAMPLE PROBLEM 15.5

### Predicting the Steps in a Reaction Sequence

**Problem** Fill in the blanks in the following reaction sequence:

**Plan** For each step, we examine the functional group of the reactant and the reagent above the yield arrow to decide on the most likely product.

**Solution** The sequence starts with an alkyl halide reacting with  $\text{OH}^-$ . Substitution gives an alcohol. Oxidation of this alcohol with acidic dichromate gives a ketone. Finally, a two-step reaction of a ketone with  $\text{CH}_3\text{Li}$  and then water forms an alcohol with a carbon skeleton that has the  $\text{CH}_3\text{—}$  group attached to the carbonyl C:

**Check** In this case, make sure that the first two reactions alter the functional group only and that the final steps change the C skeleton.

### FOLLOW-UP PROBLEMS

**15.5A** Determine the organic product of each of the following reactions:

(Hint: Lithium aluminum hydride,  $\text{LiAlH}_4$ , is an important reducing agent in organic reactions; the second step of the reaction requires  $\text{H}_2\text{O}$ .)

**15.5B** Choose reactants that will yield the following products:

**SOME SIMILAR PROBLEMS** 15.65–15.74

**Variations on a Theme: Inorganic Compounds with Double Bonds** Homonuclear (same kind of atom) double bonds are rare for atoms other than C. However, we've seen many double bonds between O and other nonmetals, for example, in the oxides of S, N, and the halogens. Like carbonyl compounds, these substances undergo addition reactions. For example, the partially negative O of water attacks the partially positive S of  $\text{SO}_3$  to form sulfuric acid:

## Functional Groups with Both Single and Double Bonds

A family of three functional groups contains C double bonded to O (a carbonyl group) and single bonded to O or N. The parent of the family is the **carboxylic acid** group,

$\text{—}\overset{\text{:O:}}{\parallel}{\text{C}}\text{—}\ddot{\text{O}}\text{H}$ , also called the *carboxyl group* and written  $\text{—COOH}$ . *The most important reaction type of this family is substitution from one member to another.* Substitution

for the  $\text{—OH}$  by the  $\text{—OR}$  of an alcohol gives the **ester** group,  $\text{—}\overset{\text{:O:}}{\parallel}{\text{C}}\text{—}\ddot{\text{O}}\text{—R}$ , and substi-

tution for the  $\text{—OH}$  by the  $\text{—}\ddot{\text{N}}\text{—}$  of an amine gives the **amide** group,  $\text{—}\overset{\text{:O:}}{\parallel}{\text{C}}\text{—}\ddot{\text{N}}\text{—}$ .

**Carboxylic Acids** Carboxylic acids,  $\text{R—}\overset{\text{O}}{\parallel}{\text{C}}\text{—OH}$ , are named by dropping the *-e* from the alkane name and adding *-oic acid*; however, many common names are used. For example, the four-C acid is **butanoic acid** (the carboxyl C is counted when choosing the root); its common name is *butyric acid*. Figure 15.22 shows some important carboxylic acids. The carboxyl C already has three bonds, so it forms only one other. In formic acid (methanoic acid), the carboxyl C is bonded to an H, but in all other carboxylic acids it is bonded to a chain or ring.

Carboxylic acids are weak acids in water:

At equilibrium in a solution of typical concentration, more than 99% of the acid molecules are undissociated at any given moment. In strong base, however, a carboxylic acid reacts completely to form a salt and water:

### Methanoic acid (formic acid)

An irritating component of ant and bee stings

### Butanoic acid (butyric acid)

Odor of rancid butter; suspected component of monkey sex attractant

### Benzoic acid

Calorimetric standard; used in preserving food, dyeing fabric, curing tobacco

### Octadecanoic acid (stearic acid)

Found in animal fats; used in making candles and soaps

**Figure 15.22** Some molecules with the carboxylic acid functional group.

The anion of the salt is the *carboxylate ion*, named by dropping *-oic acid* and adding *-oate*; the sodium salt of butanoic acid, for instance, is sodium butanoate.

Carboxylic acids with long hydrocarbon chains are **fatty acids**, an essential group of compounds found in all cells. Animal fatty acids have saturated chains (see stearic acid, Figure 15.22, *bottom*), whereas many fatty acids from plants are unsaturated, usually with the C=C bonds in the *cis* configuration. The double bonds make them much easier to metabolize. Nearly all fatty acid skeletons have an even number of C atoms—16 and 18 carbons are very common—because cells use two-carbon units in synthesizing them. Fatty acid salts, usually with a cation from Group 1A(1) or 2A(2), are soaps (Section 13.2).

Substitution of carboxylic acids and other members of this family occurs through a two-step sequence: *addition plus elimination equals substitution*. Addition to the trigonal planar C atom gives an unstable tetrahedral intermediate, which immediately undergoes elimination to revert to a trigonal planar product (in this case, X is OH):

Strong heating of a carboxylic acid forms an **acid anhydride** through a type of substitution called a *dehydration-condensation reaction* (Section 14.7). Viewing this reaction as similar to the one above, but where X is OH, Z is H, and Y is the OOC—R group, we see the result is that two molecules condense into one with loss of a water molecule:

**Esters** An ester,  $\text{R}-\overset{\text{O}}{\parallel}{\text{C}}-\text{O}-\text{R}$ , is formed from an alcohol and a carboxylic acid. The first part of an ester name designates the alcohol portion and the second the acid portion (named in the same way as the carboxylate ion). For example, the ester formed between ethanol and ethanoic acid is **ethyl ethanoate** (common name, ethyl acetate), a solvent for nail polish and model glue.

The ester group occurs commonly in **lipids**, a large group of fatty biological substances. Most dietary fats are *triglycerides*, esters that are composed of three fatty acids linked to the alcohol 1,2,3-trihydroxypropane (common name, glycerol) and that function as energy stores. Some important lipids are shown in Figure 15.23; lecithin is one of several phospholipids that make up the lipid bilayer in all cell membranes (Section 13.2).

Figure 15.23 Some lipid molecules with the ester functional group.

Esters, like acid anhydrides, form through a dehydration-condensation reaction; in this case, it is called an *esterification*:

Note that the esterification reaction is reversible. The opposite of dehydration-condensation is **hydrolysis**, in which the O atom of water is attracted to the partially positive C atom of the ester, cleaving (lysing) the ester molecule into two parts. One part bonds to water's —OH, and the other part to water's other H. In the process of soap manufacture, or *saponification* (Latin *sapon*, “soap”), used since ancient times, the ester bonds in animal or vegetable fats are hydrolyzed with a strong base:

While carboxylic acids have pungent, vinegary, or cheesy odors, esters have pleasant odors. For example, ethyl butanoate has the scent of pineapple, and pentyl-pentanoate has the aroma of apples (*see photo*). Naturally occurring and synthetic esters are used to add fruity, floral, and herbal odors to foods, cosmetics, household deodorizers, and medicines.

**Amides** The product of a substitution between an amine (or NH<sub>3</sub>) and an ester is an

amide,  $\text{R}-\overset{\text{O}}{\parallel}{\text{C}}-\text{N}-$ . The partially negative N of the amine is attracted to the partially positive C of the ester, an alcohol (ROH) is lost, and an amide forms:

Amides are named by denoting the amine portion with *N*- (note that it is italic) and replacing *-oic acid* from the parent carboxylic acid with *-amide*. In the amide produced in the preceding reaction, the ethyl group comes from the amine, and the acid portion comes from ethanoic acid (acetic acid). Some amides are shown in Figure 15.24. The most important example of the amide group is the *peptide bond* (discussed in Sections 13.2 and 15.6), which links amino acids in a protein.

**Figure 15.24** Some molecules with the amide functional group.

**Acetaminophen**

Active ingredient in nonaspirin pain relievers; used to make dyes and photographic chemicals

***N,N*-Dimethylmethanamide (dimethylformamide)**

Major organic solvent; used in production of synthetic fibers

**Lysergic acid diethylamide (LSD-25)** A potent hallucinogen

Carboxylic acids and esters have some familiar and distinctive odors.

Source: © Jill Braaten

An amide is hydrolyzed in hot water (or base) to a carboxylic acid (or carboxylate ion) and an amine. Thus, even though amides are not normally formed in the following way, they can be viewed as the result of a reversible dehydration-condensation:

**Reduction Reactions** Compounds in the carboxylic acid family also undergo reduction to form other functional groups. For example, certain inorganic *reducing agents* (such as lithium aluminum hydride,  $\text{LiAlH}_4$ , or sodium borohydride,  $\text{NaBH}_4$ ) convert acids or esters to alcohols and convert amides to amines:

**SAMPLE PROBLEM 15.6****Predicting Reactions of the Carboxylic Acid Family**

**Problem** Predict the organic product(s) of the following reactions:

**Plan** (a) A carboxylic acid and an alcohol react, so the reaction must be a substitution to form an ester and water. (b) An amide reacts with  $\text{OH}^-$ , so it is hydrolyzed to an amine and a sodium carboxylate.

**Solution** (a) Formation of an ester:

(b) Basic hydrolysis of an amide:

**Check** Note that in part (b), the carboxylate ion forms, rather than the acid, because the aqueous  $\text{NaOH}$  that is present reacts with any carboxylic acid as it forms.

**FOLLOW-UP PROBLEMS**

**15.6A** Predict the organic product(s) of the following reactions:

**15.6B** Fill in the blanks in the following reactions:

**SOME SIMILAR PROBLEMS** 15.67–15.74

**Figure 15.25** The formation of carboxylic, phosphoric, and sulfuric acid anhydrides.

**Variations on a Theme: Oxoacids, Esters, and Amides of Other Nonmetals** A nonmetal that has both double and single bonds to oxygens occurs in most inorganic oxoacids, such as phosphoric, sulfuric, and chlorous acids. Those with additional O atoms are stronger acids than carboxylic acids.

Diphosphoric and disulfuric acids are acid anhydrides formed by dehydration-condensation reactions, like the one that yields a carboxylic acid anhydride (Figure 15.25). Inorganic oxoacids form esters and amides that are part of many biological molecules. We already saw that certain lipids are phosphate esters (see Figure 15.23). The first compound formed when glucose is digested is a phosphate ester (Figure 15.26A); a similar phosphate ester is a major structural feature of nucleic acids, as we'll see shortly. Amides of organic sulfur-containing oxoacids, called *sulfonamides*, are potent antibiotics; the simplest of these is depicted in Figure 15.26B. More than 10,000 different sulfonamides have been synthesized.

**Figure 15.26** A phosphate ester and a sulfonamide.

## Functional Groups with Triple Bonds

Alkynes and nitriles are the only two important functional groups with triple bonds.

**Alkynes** Alkynes, with an electron-rich  $\text{—C}\equiv\text{C—}$  group, undergo addition (by  $\text{H}_2\text{O}$ ,  $\text{H}_2$ ,  $\text{HX}$ ,  $\text{X}_2$ , and so forth) to form double-bonded or saturated compounds:

**Nitriles** Nitriles ( $\text{R—C}\equiv\text{N}$ ) contain the **nitrile** group ( $\text{—C}\equiv\text{N:}$ ) and are made by substituting a  $\text{CN}^-$  (cyanide) ion for  $\text{X}^-$  in a reaction with an alkyl halide:

This reaction is useful because it *increases the chain by one C atom*. Nitriles are versatile because once they are formed, they can be reduced to amines or hydrolyzed to carboxylic acids:

**Variations on a Theme: Inorganic Compounds with Triple Bonds** Triple bonds are as scarce in the inorganic world as in the organic world. Carbon monoxide ( $\text{:C}\equiv\text{O:}$ ), elemental nitrogen ( $\text{:N}\equiv\text{N:}$ ), and the cyanide ion ( $\text{[:C}\equiv\text{N:}]^-$ ) are the only common examples.

You've seen quite a few functional groups by this time, and it is especially important that you can recognize them in a complex organic molecule. Sample Problem 15.7 provides some practice.

## SAMPLE PROBLEM 15.7

## Recognizing Functional Groups

**Problem** Circle and name the functional groups in the following molecules:

**Plan** We use Table 15.5 to identify the various functional groups.

## FOLLOW-UP PROBLEMS

**15.7A** Circle and name the functional groups:

**15.7B** Circle and name the functional groups:

**SOME SIMILAR PROBLEMS** 15.59 and 15.60

## Summary of Section 15.4

- > Organic reactions are initiated when regions of high and low electron density in reactant molecules attract each other.
- > Functional groups containing only single bonds—alcohols, haloalkanes, and amines—undergo substitution and elimination reactions.
- > Functional groups with double or triple bonds—alkenes, aldehydes, ketones, alkynes, and nitriles—mostly undergo addition reactions.
- > Aromatic compounds typically undergo substitution, rather than addition, because delocalization of the  $\pi$  electrons stabilizes the ring.
- > Functional groups with both double and single bonds—carboxylic acids, esters, and amides—undergo substitution (addition plus elimination) reactions.
- > Many reactions change one functional group to another, but some, including reactions with organometallic compounds and with the cyanide ion, change the carbon skeleton.

## 15.5 THE MONOMER-POLYMER THEME I: SYNTHETIC MACROMOLECULES

In Chapter 12, you saw that polymers are extremely large molecules that consist of many monomeric repeat units. There, we focused on the mass, shape, and physical properties of polymers. Now we'll discuss the two types of organic reactions that link monomers covalently into a chain. To name a polymer, we add the prefix *poly-* to the monomer name, as in *polyethylene* or *polystyrene*. When the monomer has a two-word name, parentheses are used, as in *poly(vinyl chloride)*.

The two major types of reaction processes that form synthetic polymers lend their names to the resulting classes of polymer—addition and condensation.

### Addition Polymers

**Addition polymers** form when monomers undergo an addition reaction with one another. These substances are also called *chain-reaction* (or *chain-growth*) *polymers* because as each monomer adds to the chain, it forms a new reactive site to continue the process. The monomers of most addition polymers have the  $\text{C}=\text{C}$  grouping.

As you can see from Table 15.6, the remarkably different physical behaviors of an acrylic sweater, a plastic grocery bag, and a bowling ball result from the different groups that are attached to the double-bonded C atoms of the monomers.

The *free-radical polymerization* of ethene (ethylene,  $\text{CH}_2=\text{CH}_2$ ) to polyethylene is a simple example of the addition process (Figure 15.27). The monomer reacts to form a *free radical*, a species with an unpaired electron, which forms a covalent bond with an electron from another monomer:

- Step 1. The process begins when an *initiator*, usually a peroxide, generates a free radical.
- Step 2. The free radical attacks the  $\pi$  bond of an ethylene molecule, forming a  $\sigma$  bond with one of the  $p$  electrons and leaving the other unpaired, creating a new free radical.
- Step 3. This new free radical attacks the  $\pi$  bond of another ethylene, joining it to the chain end, and the backbone of the polymer grows one unit longer.
- Step 4. This process stops when two free radicals form a covalent bond or when a very stable free radical is formed by addition of an *inhibitor* molecule.

Recent progress in controlling the high reactivity of free-radical species promises an even wider range of polymers. In one method, polymerization is initiated by the formation of a cation (or anion) instead of a free radical. The cationic (or anionic) reactive end of the chain attacks the  $\pi$  bond of another monomer to form a new cationic (or anionic) end, and the process continues.

The most important polymerization reactions take place under relatively mild conditions through the use of catalysts that incorporate transition metals. In 1963, Karl Ziegler and Giulio Natta received the Nobel Prize in chemistry for developing *Ziegler-Natta catalysts*, which employ an organoaluminum compound, such as  $\text{Al}(\text{C}_2\text{H}_5)_3$ , and the tetrachloride of titanium or vanadium. Today, chemists use organometallic catalysts that are *stereoselective* to create polymers whose repeat units have groups spatially oriented in particular ways. Use of these catalysts with varying conditions and reagents allows polyethylene chains with molar masses of  $10^4$  to  $10^5$  g/mol to be made.

Similar methods are used to make polypropylenes,  $\text{[-CH}_2\text{-CH(CH}_3\text{)]}_n$ , that have

all the  $\text{CH}_3$  groups of the repeat units oriented either on one side of the chain or on alternating sides. The different orientations lead to different packing efficiencies of the chains and, thus, different degrees of crystallinity, which lead to differences in such physical properties as density, rigidity, and elasticity (Section 12.7).

Figure 15.27 Steps in the free-radical polymerization of ethylene.

Table 15.6

## Some Major Addition Polymers

			
Monomer		Polymer	Applications
		polyethylene (R <sub>1</sub> = R <sub>2</sub> = R <sub>3</sub> = R <sub>4</sub> = H)	Plastic bags; bottles; toys
		polytetrafluoroethylene (R <sub>1</sub> = R <sub>2</sub> = R <sub>3</sub> = R <sub>4</sub> = F)	Cooking utensils (e.g., Teflon)
		polypropylene (R <sub>1</sub> = R <sub>2</sub> = R <sub>3</sub> = H; R <sub>4</sub> = CH <sub>3</sub> )	Carpeting (indoor-outdoor); bottles
		poly(vinyl chloride) (R <sub>1</sub> = R <sub>2</sub> = R <sub>3</sub> = H; R <sub>4</sub> = Cl)	Plastic wrap; garden hose; indoor plumbing
		polystyrene (R <sub>1</sub> = R <sub>2</sub> = R <sub>3</sub> = H; R <sub>4</sub> = C <sub>6</sub> H <sub>5</sub> )	Insulation; furniture; packing materials
		polyacrylonitrile (R <sub>1</sub> = R <sub>2</sub> = R <sub>3</sub> = H; R <sub>4</sub> = CN)	Yarns (e.g., Orlon, Acrilan); fabrics; wigs
		poly(vinyl acetate) (R <sub>1</sub> = R <sub>2</sub> = R <sub>3</sub> = H; R <sub>4</sub> = OC(=O)CH <sub>3</sub> )	Adhesives; paints; textile coatings; computer disks
		poly(vinylidene chloride) (R <sub>1</sub> = R <sub>2</sub> = H; R <sub>3</sub> = R <sub>4</sub> = Cl)	Food wrap (e.g., Saran)
		poly(methyl methacrylate) (R <sub>1</sub> = R <sub>2</sub> = H; R <sub>3</sub> = CH <sub>3</sub> ; R <sub>4</sub> = CO(=O)CH <sub>3</sub> )	Glass substitute (e.g., Lucite, Plexiglas); bowling balls; paint

## Condensation Polymers

The monomers of **condensation polymers** must have *two functional groups*; we can designate such a monomer as A—R—B (where A and B may or may not be the same, and R is the rest of the molecule). Most commonly, the monomers link when an A group on one undergoes a *dehydration-condensation reaction* with a B group on another:

Many condensation polymers are *copolymers*, those consisting of two or more different repeat units (Section 12.7). Two major types are polyamides and polyesters.

1. *Polyamides*. Condensation of carboxylic acid and amine monomers forms *polyamides* (*nylons*). One of the most common is *nylon-66*, manufactured by mixing equimolar amounts of a six-C diamine (1,6-diaminohexane) and a six-C diacid (1,6-hexanedioic acid). The basic amine reacts with the acid to form a “nylon salt.” Heating drives off water and forms the amide bonds:

**Figure 15.28** The formation of nylon-66. In the laboratory, the six-C diacid chloride, which is more reactive than the diacid, is used as one monomer; the polyamide forms between the two liquid phases.

Source: © McGraw-Hill Education/Charles Winters/Timeframe Photography, Inc.

In the laboratory, this nylon is made without heating by using a more reactive acid component (Figure 15.28). Covalent bonds within the chains give nylons great strength, and H bonds between chains give them great flexibility (see Table 2.8). About half of all nylons are made to reinforce automobile tires; the others are used for rugs, clothing, fishing line, and so forth.

2. *Polyesters*. Condensation of carboxylic acid and alcohol monomers forms *polyesters*. Dacron, a popular polyester fiber, is woven from polymer strands formed when equimolar amounts of 1,4-benzenedicarboxylic acid and 1,2-ethanediol react:

Blending these polyester fibers with various amounts of cotton gives fabrics that are durable, easily dyed, and crease-resistant. Extremely thin Mylar films, used for recording tape and food packaging, are also made from this polymer.

**Variations on a Theme: Inorganic Polymers** You already know that some synthetic polymers have inorganic backbones. In Chapter 14, we discussed the silicones, polymers with the repeat unit  $-(\text{R}_2)\text{Si}-\text{O}-$ . Depending on the chain crosslinks and the R groups, silicones range from oily liquids to elastic sheets to rigid solids and have applications that include artificial limbs and space suits. Polyphosphazenes exist as flexible chains even at low temperatures and have the repeat unit  $-(\text{R}_2)\text{P}=\text{N}-$ .

### › Summary of Section 15.5

- › Polymers are extremely large molecules that are made of repeat units called monomers.
- › Addition polymers are formed from unsaturated monomers that commonly link through free-radical reactions.
- › Most condensation polymers are formed by linking monomers that each have two functional groups through a dehydration-condensation reaction.
- › Reaction conditions, catalysts, and monomers can be varied to produce polymers with different properties.

## 15.6 THE MONOMER-POLYMER THEME II: BIOLOGICAL MACROMOLECULES

The monomer-polymer theme was being played out in nature eons before humans employed it to such great advantage. Biological macromolecules are condensation polymers created by nature's reaction chemistry and improved through evolution. These remarkable molecules are the best demonstration of the versatility of carbon and its handful of atomic partners.

*Natural polymers*, such as polysaccharides, proteins, and nucleic acids, are the "stuff of life." Some have structures that make wood strong, fingernails hard, and wool flexible. Others speed up the myriad reactions that occur in every cell or defend the body against infection. Still others possess the genetic information organisms need to forge other biomolecules and reproduce themselves. Remarkable as these giant molecules are, the functional groups of their monomers and the reactions that link them are identical to those of other, smaller organic molecules. Moreover, as you saw in Section 13.2, the same intermolecular forces that dissolve smaller molecules stabilize these giant molecules in the aqueous medium of the cell.

### Sugars and Polysaccharides

In essence, the same chemical change occurs when you burn a piece of wood or eat a piece of bread. Wood and bread are mixtures of *carbohydrates*, substances that provide energy through oxidation.

**Figure 15.29** The structure of glucose in aqueous solution (A) and the formation of a disaccharide (B).

**Monomer Structure and Linkage** Glucose and other simple sugars, from the three-*C trioses* to the seven-*C heptoses*, are called **monosaccharides** and consist of carbon chains with attached hydroxyl and carbonyl groups. In aqueous solution, an *OH* (alcohol) group and a *C=O* (aldehyde or ketone) group of the same monosaccharide react with each other to form a cyclic molecule that has either a five- or six-membered ring. For example, glucose undergoes an internal addition reaction between the aldehyde group of C-1 and the alcohol group of C-5 (Figure 15.29A).

When two monosaccharides undergo a dehydration-condensation reaction, a **disaccharide** forms. For example,

- sucrose (table sugar) is a disaccharide of glucose (linked at C-1) and fructose (linked at C-2) (Figure 15.29B);
- lactose (milk sugar) is a disaccharide of glucose (C-1) and galactose (C-4);
- maltose, used in brewing and as a sweetener, is a disaccharide of two glucose units (linked from C-1 to C-4).

**Three Major Types of Polysaccharides** In addition to their roles as individual molecules engaged in energy metabolism, monosaccharides serve as the monomer units of **polysaccharides**. The three major natural polysaccharides—cellulose, starch, and glycogen—consist entirely of glucose units, but they differ in the ring positions of the links, in the orientation of certain bonds, and in the extent of crosslinking. Some other polysaccharides contain nitrogen in their attached groups. *Chitin* (pronounced “KY-tin”), the main component of the tough, external skeletons of insects and crustaceans (see photo), has an acetamide group at C-2 of the glucose ring.

1. *Cellulose* is the most abundant organic chemical on Earth. More than 50% of the carbon in plants occurs in the cellulose of stems and leaves, and wood is largely cellulose. Cellulose consists of long chains of glucose. The great strength of wood is due largely to the countless H bonds between cellulose chains. The monomers are linked in a particular way from C-1 in one unit to C-4 in the next. Humans lack the enzymes to break this link, so we cannot digest cellulose (unfortunately!); however, microorganisms in the digestive tracts of some animals, such as cows, sheep, and termites, can.

2. *Starch* is a mixture of polysaccharides of glucose and serves as an *energy store* in plants. When a plant needs energy, some starch is broken down by hydrolysis of the bonds between units, and the released glucose is oxidized through a multistep metabolic pathway. Starch occurs in plant cells as insoluble granules of amylose, a helical molecule of several thousand glucose units, and amylopectin, a highly branched, bushlike

Lobster shells contain a polysaccharide called *chitin*.

Source: © McGraw-Hill Education/Pat Watson, photographer

molecule of up to a million glucose units. Most of the glucose units are linked by C-1 to C-4 bonds, as in cellulose, but a different orientation around the chiral C-1 allows our digestive enzymes to break starch down into monomers, which we metabolize for energy. A C-6 to C-1 crosslink joins glucose chains in a starch molecule every 24 to 30 units.

3. *Glycogen* functions as the energy storage molecule in animals. It occurs in liver and muscle cells as large, insoluble granules consisting of polymer molecules made up of 1000 to more than 500,000 glucose units. In glycogen, these units are linked by C-1 to C-4 bonds, as in starch, but the molecule is more highly crosslinked than starch, with C-6 to C-1 crosslinks every 8 to 12 units.

## Amino Acids and Proteins

As you saw in Section 15.5, synthetic polyamides (such as nylon-66) are formed from two monomers, one with a carboxyl group at each end and the other with an amine group at each end. **Proteins**, the polyamides of nature, are *unbranched* polymers formed from monomers called **amino acids**: *each amino acid molecule has both a carboxyl group and an amine group* (Section 13.2).

**Monomer Structure and Linkage** An amino acid has both its carboxyl group and its amine group attached to the  $\alpha$ -carbon, the second C atom in the chain. Proteins are made up of about 20 different types of amino acids, distinguished by their R groups, which range from an H atom to a polycyclic N-containing aromatic structure (Figure 15.30). The R groups play a major role in the shape and function of the protein.

In the aqueous cellular fluid, the  $\text{NH}_2$  and  $\text{COOH}$  groups of amino acids are charged because the carboxyl groups each transfer an  $\text{H}^+$  ion to  $\text{H}_2\text{O}$  to form  $\text{H}_3\text{O}^+$

**Figure 15.30** The common amino acids. The R groups are screened gray, and the  $\alpha$ -carbons (*boldface*), with carboxyl and amino groups, are screened yellow. Here the amino acids are shown with the charges they have under physiological conditions.

ions, which effectively transfer the  $H^+$  to the amine groups. Occurring throughout the solution, the overall process can be viewed as an intramolecular acid-base reaction:

An H atom is the third group bonded to the  $\alpha$ -carbon, and the fourth is the R group (also called the *side chain*).

Each amino acid is linked to the next through a *peptide (amide) bond* formed by a dehydration-condensation reaction in which the carboxyl group of one monomer reacts with the amine group of the next.

Therefore, the polypeptide chain—the backbone of the protein—has a repeating structure that consists of an  $\alpha$ -carbon bonded to a peptide group bonded to the next  $\alpha$ -carbon bonded to the next peptide group, and so forth (see Figure 13.6). The various R groups dangle from the  $\alpha$ -carbons on alternate sides of the chain.

**The Hierarchy of Protein Structure** Each protein has its own amino acid composition, specific proportions of the various amino acids. However, it is not the composition that defines the protein's role in the cell; rather, *the sequence of amino acids determines the protein's shape and function*. Proteins range from about 50 to several thousand amino acids, yet from a purely mathematical point of view, even a small protein of 100 amino acids has a virtually limitless number of possible sequences of 20 different amino acids ( $20^{100} \approx 10^{130}$ ). In fact, though, only a tiny fraction of these possibilities occur in actual proteins. For example, even in an organism as complex as a human being, there are only about  $10^5$  different types of proteins.

A protein folds into its native shape as it is being synthesized in the cell. Some shapes are simple—long helical tubes or undulating sheets. Others are far more complex—baskets, Y shapes, spheroid blobs, and countless other globular forms. Biochemists define a hierarchy for the overall structure of a protein (Figure 15.31):

1. *Primary ( $1^\circ$ ) structure*, the most basic level, refers to the sequence of covalently bonded amino acids in the polypeptide chain.

**Figure 15.31** The structural hierarchy of proteins.

2. *Secondary* ( $2^\circ$ ) *structure* refers to sections of the chain that, as a result of H bonding between nearby peptide groupings, adopt shapes called  $\alpha$ -helices and  $\beta$ -pleated sheets.
3. *Tertiary* ( $3^\circ$ ) *structure* refers to the three-dimensional folding of the whole polypeptide chain, which results from a combination of mostly intermolecular forces (Figure 13.7). In many proteins, characteristic folding patterns form regions that play a role in the protein's function—binding a hormone, attaching to a membrane, forming a membrane channel, and so forth.
4. *Quaternary* ( $4^\circ$ ) *structure*, the most complex level, occurs in proteins made up of several polypeptide chains (subunits) and refers to the way the chains assemble, typically through intermolecular forces, into the overall multi-subunit protein. Hemoglobin, for example, consists of four subunits (rightmost structure in Figure 15.31).

The key point is that *only the  $1^\circ$  structure relies on covalent bonds; the  $2^\circ$ ,  $3^\circ$ , and  $4^\circ$  structures rely primarily on intermolecular forces* (Section 13.2).

**The Relation Between Structure and Function** Two broad classes of proteins differ in the complexity of their amino acid compositions and sequences and, therefore, in their structure and function:

1. *Fibrous proteins* have relatively simple amino acid compositions and correspondingly simple structures. They are key components of hair, wool, skin, and connective tissue—materials that require strength and flexibility. Like synthetic polymers, these proteins have a small number of different amino acids in a repeating sequence.

- *Collagen*, the most common animal protein, makes up as much as 40% of human body weight. More than 30% of its amino acids are glycine (G) and another 20% are proline (P). It consists of three chains, each an extended helix, that wind around each other. The peptide C=O groups in one chain form H bonds to the peptide N—H groups in another. The result is a long, triple-helical cable with the sequence —G—X—P—G—X—P— and so on (where X is another amino acid) (Figure 15.32A). As the main protein component of tendons, skin, and blood-vessel walls, collagen has a high tensile strength: a collagen strand 1-mm in diameter can support a 10-kg weight!
- *Silk fibroin*, which is secreted by the silk moth caterpillar, has glycine, alanine, and serine making up more than 85% of its amino acids (Figure 15.32B). Running back and forth alongside each other, fibroin chain segments form interchain H bonds to create a *pleated sheet*. Stacks of sheets interact through dispersion forces, which make fibroin strong and flexible but not very stretchable—perfect for a silkworm's cocoon.

2. *Globular proteins* have much more complex compositions, often containing all 20 amino acids in varying proportions. As the name implies, globular proteins are typically more rounded and compact, with a wide variety of shapes and a correspondingly wide range of functions: defenders against bacterial invasion, messengers that trigger cell actions, catalysts of chemical change, membrane gatekeepers that maintain cellular concentrations, and many others.

The locations of particular amino-acid R groups are crucial to the protein's function. For example, in catalytic proteins, a few R groups form a crevice that closely matches the shapes of reactant molecules. These groups typically hold the reactants through intermolecular forces and speed their reaction to products by bringing them together and twisting and stretching their bonds (Section 16.7). Experiment has established that a slight change in one of these critical R groups decreases the catalytic function dramatically. This fact supports the essential idea that *the protein's amino acid sequence determines its structure, which in turn determines its function*:

## Nucleotides and Nucleic Acids

*The amino acid sequence of every protein in every organism is prescribed by the genetic information held within the organism's nucleic acids.* And, given that the proteins determine how an organism looks and behaves, no role could be more essential.

**Figure 15.32** The shapes of fibrous proteins.

Source: A: © J. Gross/SPL/Science Source; B: © Agencja Fotograficzna Caro/Alamy

**Monomer Structure and Linkage** Nucleic acids are *unbranched* polymers made up of monomers called **mononucleotides**, which consist of a sugar, an N-containing base, and a phosphate group.

1. *Sugar*. The two types of nucleic acid differ in the sugar portions of their mononucleotides: **ribonucleic acid** (RNA) contains *ribose*, a five-C sugar, and **deoxyribonucleic acid** (DNA) contains *deoxyribose*, in which H replaces OH at the 2' carbon of the sugar. (Carbon atoms in the sugar portion are given numbers with primes to distinguish them from carbon atoms in the base.)

2. *Nitrogen base*. Attached to the sugar molecule at the 1' carbon is one of four N-containing bases, either a pyrimidine (six-membered ring) or a purine (six- and five-membered rings sharing a side). The pyrimidines are cytosine (C), thymine (T), and uracil (U); thymine occurs in DNA and uracil occurs in RNA. The purines are guanine (G) and adenine (A).

3. *Phosphate group*. A phosphate group is attached to the 5' carbon of the sugar.

The cellular precursors that form a nucleic acid are *nucleoside triphosphates* (Figure 15.33A, *next page*). Dehydration-condensation reactions between them release inorganic diphosphate ( $\text{HO}_3\text{P}-\text{O}-\text{PO}_3\text{H}^{2-}$ ) and create a *phosphodiester bond* between the phosphate group on the 5' carbon of one sugar and the  $-\text{OH}$  group on the 3' carbon of a second sugar, thereby building up a polynucleotide chain. Therefore, *the repeating pattern of the nucleic acid backbone is sugar-phosphate-sugar-phosphate*, and so on (Figure 15.33B), with the bases dangling off the chain, much like the R groups dangle off the polypeptide chain of a protein.

**The Central Importance of Base Pairing** In the cell nucleus, DNA exists as two chains wrapped around each other in a **double helix** (Figure 15.34, *next page*). The polar sugar-phosphate backbone of each chain interacts with water in cellular fluid. In the DNA core, the *nonpolar bases form intrachain H bonds*, which hold the chains together. A double helical DNA molecule may contain many millions of H-bonded bases. Two features of these **base pairs** are crucial to the structure and function of DNA:

- A pyrimidine and a purine are always paired, which gives the double helix a constant diameter.
- Each base is paired with the same partner: A always with T, and G always with C. Thus, *the base sequence on one chain is the complement of the base sequence on the other*. For example, the sequence A—C—T on one chain is *always* paired with the sequence T—G—A on the other: A with T, C with G, and T with A.

Each DNA molecule is crumpled into a tangled mass that forms one of the cell's *chromosomes*. But, the DNA molecule is amazingly long and thin: if the largest human chromosome were stretched out, it would be 4 cm (more than 1.5 in) long; in the cell nucleus, however, it is wound into a structure only 5 nm in diameter—8 million times shorter! Segments of the DNA chains are the *genes* that contain the chemical information for synthesizing the organism's proteins.

**Figure 15.33** Nucleic acid precursors and their linkage.**Figure 15.34** The double helix of DNA and a section showing base pairs.

**Figure 15.35** Key stages in protein synthesis.

**Protein Synthesis** *The information content of a gene resides in its base sequence. In the genetic code, each base acts as a “letter,” each three-base sequence as a “word,” and each word codes for a specific amino acid. For example, the sequence C—A—C codes for the amino acid histidine, A—A—G codes for lysine, and so on. Through an amazingly complex series of interactions, one amino acid at a time is positioned and linked to the next to synthesize a protein. To fully appreciate this aspect of the chemical basis of biology, keep in mind that this complex process occurs largely through H bonding between base pairs.*

Protein synthesis occurs as two main operations, transcription and translation. DNA occurs in the cell nucleus, but the genetic message is decoded in the cytoplasm of the cell. Therefore, the information must be sent from the DNA to the synthesis site. RNA serves this messenger role. The entire process is shown, greatly simplified, in Figure 15.35.

**Transcription** produces a *messenger RNA* (mRNA) copy of the DNA information; that is, the information is “transcribed” from one nucleic acid to another:

- A portion of the DNA is temporarily unwound, and one chain segment acts as a template for the formation of a complementary chain of mRNA made by linking individual mononucleoside triphosphates. The DNA code words are transcribed into RNA code words through base pairing. Cytosine (C) and guanine (G) are complementary bases. Adenine (A) is the complementary base for thymine (T) in DNA, and for uracil (U) in RNA (step 1).
- The DNA rewinds, and mRNA moves out of the cell nucleus through pores in its membrane (step 2).

**Translation** uses the mRNA to synthesize the protein; that is, the genetic message is “translated” from the language of nucleotides to that of amino acids:

- The mRNA binds, again through base pairing, to an RNA-rich particle in the cell called a *ribosome* (step 3).

- *Transfer RNA* (tRNA) molecules, smaller nucleic acids, bring amino acids to the mRNA that is bound to the ribosome. Each tRNA molecule has two key portions. On one end is a three-base sequence that is *the complement of a three-base “word” on the mRNA*. On the opposite end is a *covalent binding site for the amino acid* (greatly enlarged for clarity) that is coded by that word (step 4).
- The tRNA then “shuttles” the correct amino acid to the correct position on the mRNA (step 5).
- The ribosome moves along the bound mRNA, one three-base word at a time, while each tRNA molecule H-bonds to the mRNA, thereby positioning its amino acid next to the previous one (step 6).
- When a tRNA molecule attaches to the mRNA at the ribosome, it releases its amino acid, and an enzyme (not shown) catalyzes formation of a peptide bond to the growing chain of amino acids (step 7).
- Once its amino acid has been released, the empty tRNA molecule leaves the site (step 8).

In essence, then, protein synthesis involves *transcribing* the DNA three-base words into an RNA message of three-base words, and then *translating* the word, via three-base RNA carriers, into the sequence of linked amino acids that make up a protein:

DNA BASE SEQUENCE  $\Rightarrow$  RNA BASE SEQUENCE  $\Rightarrow$  PROTEIN AMINO ACID SEQUENCE

**DNA Replication** Another complex series of interactions is involved in *DNA replication*, the process by which DNA copies itself. When a cell divides, its chromosomes are replicated, or reproduced, ensuring that the new cells have the same number and types of genes. In this process (Figure 15.36):

1. A small portion of the double helix is “unzipped,” so each DNA chain can act as a template for a new chain.
2. The bases in each DNA chain are H-bonded with the complementary bases of free mononucleoside triphosphate units.
3. The new units are linked through phosphodiester bonds to form a new chain in a process catalyzed by an enzyme called *DNA polymerase*. Gradually, each of the unzipped chains forms the complementary half of a double helix, which results in *two* double helices.

Because each base always pairs with its complement, the original double helix is copied and the genetic makeup of the cell preserved. (Base pairing is central to methods for learning the sequence of nucleotides in genes, and for analyzing evidence in criminal investigations, as the following Chemical Connections essay shows.)

Figure 15.36 Key stages in DNA replication.

Thanks to *DNA sequencing*, the process of determining the identity and order of DNA bases, we now know the sequence of the 3 billion nucleotide base pairs in the DNA of the entire human genome! Sequencing has become indispensable to molecular biology and biochemical genetics.

Just as indispensable to forensic science is *DNA fingerprinting* (or *DNA profiling*), a different process that employs similar methods. Since the discovery that portions of an individual's DNA are as unique as fingerprints, this technique has been applied in countless situations, from confirming the parents of a child to identifying the victims of a terrorist attack.

### DNA Sequencing

A given chromosome in the nucleus of a human cell may have 100 million nucleotide bases, but most common sequencing processes cut the DNA into fragments of a few thousand bases. The chromosome is first broken into pieces by enzymes that cleave at specific sites. Then, to obtain enough sample for analysis, the DNA is replicated through a variety of amplification methods, which make many copies of the individual DNA fragments, called target fragments.

One of the most popular approaches is the *Sanger chain-termination method*, which uses chemically altered bases to stop the growth of a complementary DNA chain at specific locations. As you've seen, the chain consists of linked 2'-deoxyribonucleoside monophosphate units (dNMP, where N represents A, T, G, or C). The link is a phosphodiester bond from the 3'-OH of one unit to the 5'-OH of the next, and the free monomers used to construct the chain are 2'-deoxyribonucleoside triphosphates (dNTP) (Figure B15.5A). The Sanger method uses a modified monomer, called a *dideoxyribonucleoside triphosphate* (ddNTP), in which the 3'-OH group is also missing from the ribose unit (Figure B15.5B). Once a ddNTP is incorporated into the growing chain, polymerization stops because there is no 3'-OH group to form a phosphodiester bond to the next dNTP unit.

The procedure is shown in Figure B15.6. After several preparation steps, the sample to be sequenced consists of single-stranded DNA target fragments, each of which is attached to one strand of a double-stranded segment of DNA (Figure B15.6A). This sample is divided into four tubes, and to each tube is added a mixture of

(continued)

Figure B15.5 Nucleoside triphosphate monomers.

Figure B15.6 Steps in the Sanger method of DNA sequencing.

DNA polymerase, large amounts of all four dNTPs, and a small amount of one of the four ddNTPs. Thus, tube 1 contains polymerase, dATP, dGTP, dCTP, and dTTP, and, say, ddATP; tube 2 contains the same mixture with ddGTP instead of ddATP; and so forth. After polymerization is complete, each tube contains the original target fragments paired to complementary chains of varying length (Figure B15.6B). The lengths vary because in tube 1, each complementary chain ends in ddA (designated **A** in the figure); in tube 2, each ends in ddG (**G**); in tube 3, each ends in ddC (**C**); and in tube 4, each ends in ddT (**T**).

Each double-stranded product is divided into single strands, and then the complementary chains are separated by means of *high-resolution polyacrylamide-gel electrophoresis*. This technique applies an electric field to separate charged species through differences in their rate of migration through pores in a gel: the smaller the species, the faster it moves. Polynucleotide fragments can be separated by electrophoresis because they have charged phosphate groups. High-resolution gels have pores that vary so slightly in size they can separate fragments differing by only a single nucleotide.

In this step, each sample is applied to its own “lane” on a gel. After electrophoresis, the gel is scanned to locate the chains, which appear in bands. Because all four ddNTP’s were used, all possible chain fragments are formed, so the sequence of the original DNA fragment can be determined (Figure B15.6C).

An automated approach begins with each ddNTP tagged with a different fluorescent dye that emits light of a distinct color. The entire mixture of complementary chains is introduced onto the gel and separated. The gel is scanned by a laser, which activates the dyes. The variation in fluorescent intensity versus distance along the chain is detected and plotted by a computer (Figure B15.6D).

## DNA Fingerprinting

Modern techniques of DNA fingerprinting require less than 1 ng of DNA. Thus, in addition to blood and semen, licked stamps and envelopes, chewed gum, and clothing containing dead skin cells can also be sources of DNA.

Currently, the most successful and widely used DNA profiling procedure is called *short tandem repeat (STR) analysis*. STRs

are specific areas on a chromosome that contain short (three to seven bases) sequences that repeat themselves within the DNA molecule. There are hundreds of different types of STRs, but each person has a unique number and assortment of types. Therefore, the more STRs that are characterized, the more discriminating the analysis.

Once the STRs have been amplified (multiple copies made), they are separated by electrophoresis, and an analyst determines the number of base repeats within each STR. In Figure B15.7, stained gels containing the STRs of DNA in blood samples from several suspects are compared with STRs from a blood stain at the crime scene. Suspect 3 has a pattern of STRs identical to that in the crime scene sample.

**Figure B15.7** STR analysis of DNA in the blood of seven suspects and in a blood stain found at the crime scene.

## Problems

**B15.4** If you were analyzing a DNA fragment with the base sequence TACAGGTTTCAGT, how many complementary chain pieces would you obtain in the tube containing ddATP? In the tube containing ddCTP?

**B15.5** A DNA fragment is sequenced and the following complementary chain pieces are obtained from the four tubes:

1. The ddATP tube contains ATG and ATATG.
2. The ddTTP tube contains TG and TATG.
3. The ddCTP tube contains CATATG.
4. The ddGPT tube contains G.

What is the sequence of bases in the DNA fragment? Draw a sketch of the electrophoresis gel for this fragment similar to the one shown in Figure B15.6C.

## › Summary of Section 15.6

- › The three types of natural polymers—polysaccharides, proteins, and nucleic acids—are formed by dehydration-condensation reactions.
- › Polysaccharides are formed from cyclic monosaccharides, such as glucose. Cellulose, starch, and glycogen have structural or energy-storage roles.
- › Proteins are polyamides formed from as many as 20 different types of amino acids. Fibrous proteins have extended shapes and play structural roles. Globular proteins have compact shapes and play metabolic, immunologic, and hormonal roles. The amino acid sequence of a protein determines its shape and function.
- › Nucleic acids (DNA and RNA) are polynucleotides consisting of four different types of mononucleotides. The base sequence of the DNA chain determines the sequence of amino acids in an organism's proteins. Hydrogen bonding between specific base pairs is the key to protein synthesis and DNA replication.
- › DNA sequencing is used to determine the identity and order of nucleotides in a fragment of a DNA chain. DNA fingerprinting is used to identify a person from the unique sequence of bases in his or her DNA.

## CHAPTER REVIEW GUIDE

### Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

#### Understand These Concepts

1. How carbon's atomic properties give rise to its ability to form four strong covalent bonds, multiple bonds, and chains, resulting in the great structural diversity of organic compounds (§15.1)
2. How carbon's atomic properties give rise to its ability to bond to various heteroatoms, which creates regions of charge imbalance that result in functional groups (§15.1)
3. Structures and names of alkanes, alkenes, and alkynes (§15.2)
4. The distinctions among constitutional, optical, and geometric isomers (§15.2)
5. The importance of optical isomerism in organisms (§15.2)
6. The effect of restricted rotation around a  $\pi$  bond on the structures and properties of alkenes (§15.2)
7. The nature of organic addition, elimination, and substitution reactions (§15.3)
8. The properties and reaction types of the various functional groups (§15.4):
  - Substitution and elimination for alcohols, haloalkanes, and amines
  - Addition for alkenes, alkynes, and aldehydes and ketones
  - Substitution for the carboxylic acid family (acids, esters, and amides)
9. Why delocalization of electrons causes aromatic rings to have lower reactivity than alkenes (§15.4)
10. The polarity of the carbonyl bond and the importance of organometallic compounds in addition reactions of carbonyl compounds (§15.4)
11. How addition plus elimination lead to substitution in the reactions of the carboxylic acid family (§15.4)
12. How addition and condensation polymers form (§15.5)
13. The three types of biopolymers and their monomers (§15.6)

14. How amino acid sequence determines protein shape, which determines function (§15.6)
15. How complementary base pairing controls the processes of protein synthesis and DNA replication (§15.6)
16. How DNA base sequence determines RNA base sequence, which determines amino acid sequence (§15.6)

#### Master These Skills

1. Drawing hydrocarbon structures given the number(s) of C atoms, multiple bonds, and rings (SP 15.1)
2. Naming hydrocarbons and drawing expanded, condensed, and carbon skeleton formulas (§15.2 and SP 15.2)
3. Drawing geometric isomers and identifying chiral centers of molecules (SP 15.2)
4. Recognizing the type of organic reaction from the structures of reactants and products (SP 15.3)
5. Recognizing an organic reaction as an oxidation or reduction from the structures of reactants and products (§15.3)
6. Determining reaction type and products for reactions of alcohols, haloalkanes, and amines (SP 15.4)
7. Determining the products in a stepwise reaction sequence (SP 15.5)
8. Determining the reactants in reactions involving aldehydes and ketones (SP 15.5)
9. Determining reactants and products in reactions of the carboxylic acid family (SP 15.6)
10. Recognizing and naming the functional groups in organic molecules (SP 15.7)
11. Drawing an abbreviated synthetic polymer structure based on monomer structures (§15.5)
12. Drawing small peptides from amino acid structures (§15.6)
13. Using the base sequence of one DNA strand to predict the sequence of the other (§15.6)

## Key Terms

Page numbers appear in parentheses.

acid anhydride (663)	carboxylic acid (662)	geometric ( <i>cis-trans</i> ) isomers (645)	nucleic acid (675)
addition polymer (668)	catenation (634)	haloalkane (alkyl halide) (656)	optical isomers (643)
addition reaction (651)	chiral molecule (643)	heteroatom (635)	optically active (643)
alcohol (654)	condensation polymer (669)	homologous series (639)	organic compounds (633)
aldehyde (660)	constitutional (structural) isomers (642)	hydrocarbon (636)	organometallic compound (661)
alkane (C <sub>n</sub> H <sub>2n+2</sub> ) (639)	cyclic hydrocarbon (640)	hydrolysis (664)	polarimeter (643)
alkene (C <sub>n</sub> H <sub>2n</sub> ) (644)	disaccharide (671)	isomers (641)	polysaccharide (671)
alkyl group (651)	double helix (675)	ketone (660)	protein (672)
alkyne (C <sub>n</sub> H <sub>2n-2</sub> ) (646)	elimination reaction (651)	lipid (663)	saturated hydrocarbon (639)
amide (662)	ester (662)	mononucleotide (675)	stereoisomers (642)
amine (657)	fatty acid (663)	monosaccharide (671)	substitution reaction (652)
amino acid (672)	functional group (635)	nitrile (666)	transcription (677)
aromatic hydrocarbon (647)	genetic code (677)	nuclear magnetic resonance (NMR) spectroscopy (649)	translation (677)
base pair (675)			unsaturated hydrocarbon (644)
carbonyl group (660)			

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

## 15.1A (a)

## 15.1B

15.2A (a) 3,3-diethylpentane; (b) 1-ethyl-2-methylcyclobutane; (c) *trans*-3-methyl-3-hexene; (d) 1-methyl-2-propylcyclopentane, in which ring C-1 and ring C-2 are chiral

**15.3A** (a) Substitution: OH replaces Br, but C has the same number of bonds.

(b) Substitution: OH replaces OCH<sub>3</sub>, but C has the same number of bonds.

(c) Addition: a second O is bonded to C in the product.

(b) Substitution;  $\text{N}\equiv\text{C—CH}_2\text{—CH}_2\text{—CH}_2\text{—C}\equiv\text{N}$

(b)  $\text{CH}_3\text{—CH}_2\text{—CH}_2\text{—OH}$  (An alcohol is oxidized to a carboxylic acid.)

**15.5A** (a) A ketone is reduced to an alcohol.

The ethyl group from ethyllithium adds to the carbonyl carbon, and treating with water forms an alcohol.

**15.5B** (a) An alcohol is oxidized to a ketone.

The ethyl group from ethyllithium adds to the carbonyl carbon, and treating with water forms an alcohol.

Reduction of an amide to an amine

Production of an ester from a carboxylic acid and an alcohol

Production of an amide from an ester and an amine

**15.7A**

**15.7B** (a)

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

### The Special Nature of Carbon and the Characteristics of Organic Molecules

#### Concept Review Questions

**15.1** Give the names and formulas of two carbon compounds that are organic and two that are inorganic.

**15.2** Explain each statement in terms of atomic properties:

(a) Carbon engages in covalent rather than ionic bonding.

(b) Carbon has four bonds in all its organic compounds.

(c) Carbon forms neither stable cations, like many metals, nor stable anions, like many nonmetals.

(d) Carbon atoms bond to other carbon atoms more extensively than do the atoms of any other element.

(e) Carbon forms stable multiple bonds.

**15.3** Carbon bonds to many elements other than itself.

(a) Name six elements that commonly bond to carbon in organic compounds.

(b) Which of these elements are heteroatoms?

(c) Which of these elements are more electronegative than carbon? Less electronegative?

(d) How does bonding of carbon to heteroatoms increase the number of organic compounds?

**15.4** Silicon lies just below carbon in Group 4A(14) and also forms four covalent bonds. Why aren't there as many silicon compounds as carbon compounds?

**15.5** What is the range of oxidation states for carbon? Name a compound in which carbon has its highest oxidation state and one in which it has its lowest.

**15.6** Which of these bonds to carbon would you expect to be relatively reactive: C—H, C—C, C—I, C=O, C—Li? Explain.

### The Structures and Classes of Hydrocarbons

(Sample Problems 15.1 and 15.2)

#### Concept Review Questions

**15.7** (a) What structural feature is associated with each type of hydrocarbon: alkane, cycloalkane, alkene, and alkyne?

(b) Give the general formula for each type.

(c) Which hydrocarbons are considered saturated?

**15.8** Define each type of isomer: (a) constitutional; (b) geometric; (c) optical. Which types of isomers are stereoisomers?

**15.9** Among alkenes, alkynes, and aromatic hydrocarbons, only alkenes exhibit *cis-trans* isomerism. Why don't the others?

**15.10** Which objects are asymmetric (have no plane of symmetry): (a) a circular clock face; (b) a football; (c) a dime; (d) a brick; (e) a hammer; (f) a spring?

**15.11** Explain how a polarimeter works and what it measures.

**15.12** How does an aromatic hydrocarbon differ from a cycloalkane in terms of its bonding? How does this difference affect structure?

#### Skill-Building Exercises (grouped in similar pairs)

**15.13** Draw all possible skeletons for a seven-C compound with

(a) A six-C chain and one double bond

(b) A five-C chain and one double bond

(c) A five-C ring and no double bonds

**15.14** Draw all possible skeletons for a six-C compound with

(a) A five-C chain and two double bonds

(b) A five-C chain and one triple bond

(c) A four-C ring and no double bonds

**15.15** Add the correct number of hydrogens to each of the skeletons in Problem 15.13.

**15.16** Add the correct number of hydrogens to each of the skeletons in Problem 15.14.

**15.17** Draw correct structures, by making a single change, for any that are incorrect:

**15.18** Draw correct structures, by making a single change, for any that are incorrect:

**15.19** Draw the structure or give the name of each compound:

(a) 2,3-dimethyloctane      (b) 1-ethyl-3-methylcyclohexane

**15.20** Draw the structure or give the name of each compound:

(c) 1,2-diethylcyclopentane      (d) 2,4,5-trimethylnonane

**15.21** Each of the following names is wrong. Draw structures based on them, and correct the names:

(a) 4-methylhexane      (b) 2-ethylpentane

(c) 2-methylcyclohexane      (d) 3,3-methyl-4-ethyloctane

**15.22** Each of the following names is wrong. Draw structures based on them, and correct the names:

(a) 3,3-dimethylbutane      (b) 1,1,1-trimethylheptane

(c) 1,4-diethylcyclopentane      (d) 1-propylcyclohexane

**15.23** Each of the following compounds can exhibit optical activity. Circle the chiral center(s) in each:

**15.24** Each of the following compounds can exhibit optical activity. Circle the chiral center(s) in each:

**15.25** Draw structures from the following names, and determine which compounds are optically active:

(a) 3-bromohexane      (b) 3-chloro-3-methylpentane

(c) 1,2-dibromo-2-methylbutane

**15.26** Draw structures from the following names, and determine which compounds are optically active:

(a) 1,3-dichloropentane      (b) 3-chloro-2,2,5-trimethylhexane

(c) 1-bromo-1-chlorobutane

**15.27** Which of the following structures exhibit geometric isomerism? Draw and name the two isomers in each case:

**15.28** Which of the following structures exhibit geometric isomerism? Draw and name the two isomers in each case:

**15.29** Which compounds exhibit geometric isomerism? Draw and name the two isomers in each case:

- (a) propene                                      (b) 3-hexene  
(c) 1,1-dichloroethene                      (d) 1,2-dichloroethene

**15.30** Which compounds exhibit geometric isomerism? Draw and name the two isomers in each case:

- (a) 1-pentene                                      (b) 2-pentene  
(c) 1-chloropropene                              (d) 2-chloropropene

**15.31** Draw and name all the constitutional isomers of dichlorobenzene.

**15.32** Draw and name all the constitutional isomers of trimethylbenzene.

### Problems in Context

**15.33** Butylated hydroxytoluene (BHT) is a common preservative added to cereals and other dry foods. Its systematic name is 1-hydroxy-2,6-di-*tert*-butyl-4-methylbenzene (*tert*-butyl is the common name for 1,1-dimethylethyl). Draw the structure of BHT.

**15.34** There are two compounds with the name 2-methyl-3-hexene, but only one with the name 2-methyl-2-hexene. Explain with structures.

**15.35** Any tetrahedral atom with four different groups attached can be a chiral center. Which of these species is optically active?

- (a)  $\text{CHClBrF}$                                       (b)  $\text{NBrCl}_2\text{H}^+$   
(c)  $\text{PFCIBrI}^+$                                       (d)  $\text{SeFCIBrH}$

**15.36** Breaking the  $\text{C}=\text{C}$   $\pi$  bond in a retinal molecule in the eye requires approximately 250 kJ/mol. Find the longest wavelength (in nm) of visible light that has the energy to break that  $\pi$  bond.

### Some Important Classes of Organic Reactions

(Sample Problem 15.3)

#### Concept Review Questions

**15.37** In terms of numbers of reactant and product substances, which organic reaction type corresponds to (a) a combination reaction, (b) a decomposition reaction, (c) a displacement reaction?

**15.38** The same type of bond is broken in an addition reaction and formed in an elimination reaction. Name the type.

**15.39** Can a redox reaction also be an addition, elimination, or substitution reaction? Explain with examples.

#### Skill-Building Exercises (grouped in similar pairs)

**15.40** Determine the type of each of the following reactions:

**15.41** Determine the type of each of the following reactions:

**15.42** Write equations for the following: (a) an addition reaction between  $\text{H}_2\text{O}$  and 3-hexene ( $\text{H}^+$  is a catalyst); (b) an elimination reaction between 2-bromopropane and hot potassium ethoxide,  $\text{CH}_3-\text{CH}_2-\text{OK}$  ( $\text{KBr}$  and ethanol are also products); (c) a light-induced substitution reaction between  $\text{Cl}_2$  and ethane to form 1,1-dichloroethane.

**15.43** Write equations for the following: (a) a substitution reaction between 2-bromopropane and  $\text{KI}$ ; (b) an addition reaction between cyclohexene and  $\text{Cl}_2$ ; (c) an addition reaction between 2-propanone and  $\text{H}_2$  ( $\text{Ni}$  metal is a catalyst).

**15.44** Based on the number of bonds and the nature of the bonded atoms, state whether each of the following changes is an oxidation or a reduction:

- (a)  $=\text{CH}_2$  becomes  $-\text{CH}_2-\text{OH}$   
(b)  $=\text{CH}-$  becomes  $-\text{CH}_2-$   
(c)  $\equiv\text{C}-$  becomes  $-\text{CH}_2-$

**15.45** Based on the number of bonds and the nature of the bonded atoms, state whether each of the following changes is an oxidation or a reduction:

- (a)  $-\overset{\text{O}}{\parallel}{\text{C}}-\text{OH}$  becomes  $-\overset{\text{O}}{\parallel}{\text{C}}-\text{O}-$   
(b)  $-\text{CH}_2-\text{OH}$  becomes  $=\text{CH}_2$   
(c)  $-\overset{\text{O}}{\parallel}{\text{C}}-\text{C}-$  becomes  $-\overset{\text{O}}{\parallel}{\text{C}}-\text{O}-$

**15.46** Is the organic reactant oxidized, reduced, or neither in each of the following reactions?

- (a) 2-hexene  $\xrightarrow[\text{cold OH}^-]{\text{KMnO}_4}$  2,3-dihydroxyhexane  
(b) cyclohexane  $\xrightarrow[\text{catalyst}]{\Delta}$  benzene +  $3\text{H}_2$

**15.47** Is the organic reactant oxidized, reduced, or neither in each of the following reactions?

- (a) 1-butyne +  $\text{H}_2 \xrightarrow{\text{Pt}}$  1-butene  
(b) toluene  $\xrightarrow[\Delta]{\text{KMnO}_4, \text{H}_3\text{O}^+}$  benzoic acid

### Problems in Context

**15.48** Phenylethylamine is a natural substance that is structurally similar to amphetamine. It is found in sources as diverse as almond oil and human urine, where it occurs at elevated concentrations as a result of stress and certain forms of schizophrenia.

One method of synthesizing the compound for pharmacological and psychiatric studies involves two steps:

Classify each step as an addition, elimination, or substitution.

### Properties and Reactivities of Common Functional Groups

(Sample Problems 15.4 to 15.7)

#### Concept Review Questions

**15.49** Compounds with nearly identical molar masses often have very different physical properties. Choose the compound with the higher value for each of the following properties, and explain your choice.

- (a) Solubility in water: chloroethane or methylethylamine  
 (b) Melting point: diethyl ether or 1-butanol  
 (c) Boiling point: trimethylamine or propylamine

**15.50** Fill in each blank with a general formula for the type of compound formed:

**15.51** Of the three major types of organic reactions, which do *not* occur readily with benzene? Why?

**15.52** Why does the C=O group react differently from the C=C group? Show an example of the difference.

**15.53** Many substitution reactions are initiated by electrostatic attraction between reactants. Show where this attraction arises in the formation of an amide from an amine and an ester.

**15.54** Although both carboxylic acids and alcohols contain an —OH group, one is acidic in water and the other is not. Explain.

**15.55** What reaction type is common to the formation of esters and acid anhydrides? What is the other product?

**15.56** Both alcohols and carboxylic acids undergo substitution, but the processes are very different. Explain.

#### Skill-Building Exercises (grouped in similar pairs)

**15.57** Name the type of organic compound from each description of the functional group:

(a) polar group that has only single bonds and does not include O or N; (b) group that is polar and has a triple bond; (c) group that has single and double bonds and is acidic in water; (d) group that has a double bond and must be at the end of a C chain.

**15.58** Name the type of organic compound from each description of the functional group: (a) N-containing group with single and double bonds; (b) group that is not polar and has a double bond; (c) polar group that has a double bond and cannot be at the end of a C chain; (d) group that has only single bonds and is basic in water.

**15.59** Circle and name the functional group(s) in each molecule:

**15.60** Circle and name the functional group(s) in each molecule:

**15.61** Draw all alcohols with the formula  $\text{C}_5\text{H}_{12}\text{O}$ .

**15.62** Draw all aldehydes and ketones with the formula  $\text{C}_5\text{H}_{10}\text{O}$ .

**15.63** Draw all amines with the formula  $\text{C}_4\text{H}_{11}\text{N}$ .

**15.64** Draw all carboxylic acids with the formula  $\text{C}_5\text{H}_{10}\text{O}_2$ .

**15.65** Draw the product resulting from mild oxidation of (a) 2-butanol; (b) 2-methylpropanal; (c) cyclopentanol.

**15.66** Draw the alcohol whose oxidation will produce (a) 2-methylpropanal; (b) 2-pentanone; (c) 3-methylbutanoic acid.

**15.67** Draw the organic product formed when the following compounds undergo a substitution reaction: (a) acetic acid and methylamine; (b) butanoic acid and 2-propanol; (c) formic acid and 2-methyl-1-propanol.

**15.68** Draw the organic product formed when the following compounds undergo a substitution reaction: (a) acetic acid and 1-hexanol; (b) propanoic acid and dimethylamine; (c) ethanoic acid and diethylamine.

**15.69** Draw condensed formulas for the carboxylic acid and alcohol that form the following esters:

**15.70** Draw condensed formulas for the carboxylic acid and amine that form the following amides:

**15.71** Fill in the expected organic substances:

**15.72** Fill in the expected organic substances:

**15.73** Supply the missing organic and/or inorganic substances:

**15.74** Supply the missing organic and/or inorganic substances:

### Problems in Context

**15.75** (a) Draw the four isomers of  $\text{C}_5\text{H}_{12}\text{O}$  that can be oxidized to an aldehyde. (b) Draw the three isomers of  $\text{C}_5\text{H}_{12}\text{O}$  that can be oxidized to a ketone. (c) Draw the isomers of  $\text{C}_5\text{H}_{12}\text{O}$  that cannot be easily oxidized to an aldehyde or ketone. (d) Name any isomer that is an alcohol.

**15.76** Ethyl formate ( $\text{HC(=O)—O—CH}_2\text{—CH}_3$ ) is added to foods to give them the flavor of rum. How would you synthesize ethyl formate from ethanol, methanol, and any inorganic reagents?

### The Monomer-Polymer Theme I: Synthetic Macromolecules

#### Concept Review Questions

**15.77** Name the reaction processes that lead to the two types of synthetic polymers.

**15.78** Which functional group occurs in the monomers of addition polymers? How are these polymers different from one another?

**15.79** What is a free radical? How is it involved in polymer formation?

**15.80** Which intermolecular force is primarily responsible for the different types of polyethylene? Explain.

**15.81** Which of the two types of synthetic polymer is more similar chemically to biopolymers? Explain.

**15.82** Which functional groups react to form nylons? Polyesters?

### Skill-Building Exercises (grouped in similar pairs)

**15.83** Draw an abbreviated structure for the following polymers, with brackets around the repeat unit:

**15.84** Draw an abbreviated structure for the following polymers, with brackets around the repeat unit:

(a) Teflon from

(b) Polystyrene from

### Problems in Context

**15.85** Polyethylene terephthalate (PET) is used to make synthetic fibers, such as Dacron; thin films, such as Mylar; and bottles for carbonated beverages.

PET is produced from ethylene glycol and either of two monomers, depending on whether the reaction proceeds by dehydration-condensation or by displacement. Write equations for the two syntheses. (*Hint*: The displacement is reversed by adding methanol to PET at high  $T$  and  $P$ .)

**15.86** Write a balanced equation for the reaction of dihydroxydimethylsilane (*right*) to form the condensation polymer known as Silly Putty.

### The Monomer-Polymer Theme II: Biological Macromolecules

#### Concept Review Questions

**15.87** Which type of polymer is formed from each of the following monomers: (a) amino acids; (b) alkenes; (c) simple sugars; (d) mononucleotides?

**15.88** What is the key structural difference between fibrous and globular proteins? How is it related, in general, to the proteins' amino acid composition?

**15.89** Protein shape, function, and amino acid sequence are inter-related. Which determines which?

**15.90** What linkage joins the monomers in each strand of DNA?

**15.91** What is base pairing? How does it pertain to DNA structure?

**15.92** RNA base sequence, protein amino acid sequence, and DNA base sequence are interrelated. Which determines which in the process of protein synthesis?

**Skill-Building Exercises (grouped in similar pairs)**

**15.93** Draw the R group of (a) alanine; (b) histidine; (c) methionine.

**15.94** Draw the R group of (a) glycine; (b) isoleucine; (c) tyrosine.

**15.95** Draw the structure of each of the following tripeptides:

(a) Aspartic acid-histidine-tryptophan

(b) Glycine-cysteine-tyrosine, with the charges that exist in cellular fluid

**15.96** Draw the structure of each of the following tripeptides:

(a) Lysine-phenylalanine-threonine

(b) Alanine-leucine-valine, with the charges that exist in cellular fluid

**15.97** Write the sequence of the complementary DNA strand that pairs with each of the following DNA base sequences:

(a) TTAGCC

(b) AGACAT

**15.98** Write the sequence of the complementary DNA strand that pairs with each of the following DNA base sequences:

(a) GGTTAC

(b) CCCGAA

**15.99** Write the base sequence of the DNA template from which this RNA sequence was derived: UGUUACGGA. How many amino acids are coded for in this sequence?

**15.100** Write the base sequence of the DNA template from which this RNA sequence was derived: GUAUCAUGAACUUG. How many amino acids are coded for in this sequence?

**Problems in Context**

**15.101** Protein shapes are maintained by a variety of forces that arise from interactions between the R groups of the various amino acids. Name the amino acid that possesses each R group and the force that could arise in each of the following interactions:

(a)  $-\text{CH}_2-\text{SH}$  with  $\text{HS}-\text{CH}_2-$

(b)  $-(\text{CH}_2)_4-\text{NH}_3^+$  with  $^-\text{O}-\overset{\text{O}}{\parallel}{\text{C}}-\text{CH}_2-$

(c)  $-\text{CH}_2-\overset{\text{O}}{\parallel}{\text{C}}-\text{NH}_2$  with  $\text{HO}-\text{CH}_2-$

(d)  $-\overset{\text{CH}_3}{\text{CH}}-\text{CH}_3$  with 

**15.102** Amino acids have an average molar mass of 100 g/mol. How many bases on a single strand of DNA are needed to code for a protein with a molar mass of  $5 \times 10^5$  g/mol?

**Comprehensive Problems**

**15.103** Ethers (general formula  $\text{R}-\text{O}-\text{R}'$ ) have many important uses. Until recently, methyl *tert*-butyl ether (MTBE, *below*) was used as an octane booster and fuel additive for gasoline. It increases the oxygen content of the fuel, which reduces CO emissions. MTBE is synthesized by the catalyzed reaction of 2-methylpropene with methanol.

(a) Write a balanced equation for the synthesis of MTBE. (*Hint*: Alcohols add to alkenes similarly to the way water does.)

(b) If the government required that auto fuel mixtures contain 2.7% oxygen by mass to reduce CO emissions, how many grams of MTBE would have to be added to each 100. g of gasoline?

(c) How many liters of MTBE would be in each liter of fuel mixture? (The density of both gasoline and MTBE is 0.740 g/mL.)

(d) How many liters of air (21%  $\text{O}_2$  by volume) are needed at  $24^\circ\text{C}$  and 1.00 atm to fully combust 1.00 L of MTBE?

**15.104** An alcohol is oxidized to a carboxylic acid, and 0.2003 g of the acid is titrated with 45.25 mL of 0.03811 M NaOH. (a) What is the molar mass of the acid? (b) What are the molar mass and molecular formula of the alcohol?

**15.105** Some of the most useful compounds for organic synthesis are Grignard reagents (general formula  $\text{R}-\text{MgX}$ , where X is a halogen), which are made by combining a haloalkane,  $\text{R}-\text{X}$ , with Mg. They are used to change the carbon skeleton of a starting carbonyl compound in a reaction similar to that with  $\text{R}-\text{Li}$ :

(a) What is the product, after a final step with water, of the reaction between ethanal and the Grignard reagent of bromobenzene? (b) What is the product, after a final step with water, of the reaction between 2-butanone and the Grignard reagent of 2-bromopropane? (c) There are often two (or more) combinations of Grignard reagent and carbonyl compound that will give the same product. Choose another pair of reactants to give the product in part (a). (d) What carbonyl compound must react with a Grignard reagent to yield a product with the  $-\text{OH}$  group at the *end* of the carbon chain? (e) What Grignard reagent and carbonyl compound would you use to prepare 2-methyl-2-butanol?

**15.106** Starting with the given organic reactant and any necessary inorganic reagents, explain how you would perform each of the following syntheses:

(a) From  $\text{CH}_3-\text{CH}_2-\text{CH}_2-\text{OH}$ , make  $\text{CH}_3-\overset{\text{Br}}{\text{CH}}-\text{CH}_2-\text{Br}$

(b) From  $\text{CH}_3-\text{CH}_2-\text{CH}_2-\text{OH}$ , make  $\text{CH}_3-\overset{\text{O}}{\parallel}{\text{C}}-\text{O}-\text{CH}_2-\text{CH}_3$

**15.107** Compound A, composed of C, H, and O, is heated in a 1.00-L flask to  $160.^\circ\text{C}$  until all of the A has vaporized and displaced the air. The flask is then cooled, and 2.48 g of A remains. When 0.500 g of A burns in  $\text{O}_2$ , 0.409 g of  $\text{H}_2\text{O}$  and 1.00 g of  $\text{CO}_2$  are produced. Compound A is not acidic, but it can be oxidized to compound B, which is weakly acidic: 1.000 g of B is neutralized with 33.9 mL of 0.5 M sodium hydroxide. When B is heated to  $260^\circ\text{C}$ , it gives off water and forms C, which, in solution in  $\text{CDCl}_3$  (where D is deuterium,  $^2\text{H}$ ), has one peak in its  $^1\text{H}$ -NMR spectrum. (a) What are the structures of A, B, and C? (b) Compound A is a controlled substance because it is metabolized to the weakly acidic “date rape” drug GHB,  $\text{C}_4\text{H}_8\text{O}_3$ . What are the structure and name of GHB?

**15.108** Cadaverine (1,5-diaminopentane) and putrescine (1,4-diaminobutane) are two compounds that are formed by bacterial action and are responsible for the odor of rotting flesh. Draw their structures. Suggest a series of reactions to synthesize putrescine from 1,2-dibromoethane and any inorganic reagents.

**15.109** Pyrethrins, such as jasmolin II (*facing page*), are a group of natural compounds synthesized by flowers of the genus *Chrysanthemum* (known as pyrethrum flowers) to act as insecticides.

(a) Circle and name the functional groups in jasmolin II.

(b) What is the hybridization of the numbered carbons?

(c) Which, if any, of the numbered carbons are chiral centers?

**15.110** Compound A is branched and optically active and contains C, H, and O. (a) A 0.500-g sample burns in excess  $O_2$  to yield 1.25 g of  $CO_2$  and 0.613 g of  $H_2O$ . Determine the empirical formula. (b) When 0.225 g of compound A vaporizes at 755 torr and  $97^\circ C$ , the vapor occupies 78.0 mL. Determine the molecular formula. (c) Careful oxidation of the compound yields a ketone. Name and draw compound A, and circle the chiral center.

**15.111** Ibuprofen is one of the most common anti-inflammatory drugs. (a) Identify the functional group(s) and chiral center(s) in ibuprofen. (b) Write a four-step synthesis of a racemic mixture of ibuprofen from 4-isobutylbenzaldehyde, using inorganic reactants and one organometallic reactant (see Problem 15.105).

**15.112** Which features of retinal make it so useful as a photon absorber in the visual systems of organisms?

**15.113** The polypeptide chain in proteins does not exhibit free rotation because of the partial double-bond character of the peptide bond. Explain this fact with resonance structures.

**15.114** Other nonmetals form compounds that are structurally analogous to those of carbon, but these inorganic compounds are usually more reactive. Predict any missing products and write balanced equations for each reaction: (a) the decomposition and chlorination of diborane to boron trichloride; (b) the combustion of pentaborane ( $B_5H_9$ ) in  $O_2$ ; (c) the hydrolysis of trisilane ( $Si_3H_8$ ) to silica ( $SiO_2$ ) and  $H_2$ ; (d) the complete halogenation of disilane

with  $Cl_2$ ; (e) the thermal decomposition of  $H_2S_3$  to hydrogen sulfide and sulfur molecules; (f) the hydrolysis of  $PCl_5$ .

**15.115** In addition to their use in water treatment, ion-exchange resins are used to extract Au, Ag, and Pt ions from solution. One of the most common resins consists of a polymer with a benzene-containing backbone to which sulfonic acid groups ( $-SO_3H$ ) have been added. (a) What monomer can be used to prepare the polymer backbone? (b) This polymer typically contains 4–16% crosslinking. Draw the structure of the benzene-containing monomer used to crosslink the polymer.

**15.116** Complete hydrolysis of a 100.00-g sample of a peptide gave the following amounts of individual amino acids (molar masses, in g/mol, appear in parentheses):

3.00 g of glycine (75.07)	0.90 g of alanine (89.10)
3.70 g of valine (117.15)	6.90 g of proline (115.13)
7.30 g of serine (105.10)	86.00 g of arginine (174.21)

(a) Why does the total mass of amino acids exceed the mass of peptide? (b) What are the relative numbers of amino acids in the peptide? (c) What is the minimum molar mass of the peptide?

**15.117** 2-Butanone is reduced by hydride ion donors, such as sodium borohydride ( $NaBH_4$ ), to the alcohol 2-butanol. Even though the alcohol has a chiral center, the product isolated from the redox reaction is not optically active. Explain.

**15.118** Wastewater from a cheese factory has the following composition: 8.0 g/L protein ( $C_{16}H_{24}O_5N_4$ ); 12 g/L carbohydrate ( $CH_2O$ ); and 2.0 g/L fat ( $C_8H_{16}O$ ). What is the total organic carbon (TOC) of the wastewater in g/L?

**15.119** Structures A, B, and C show the three common forms of vitamin A. (a) Match each structure with the correct vitamin A compound: retinal (an aldehyde), retinol (an alcohol), and retinoic acid (a carboxylic acid). (b) Retinal, the molecule responsible for the chemistry of vision, can be converted to retinol or to retinoic acid. Identify each of these reactions as a reduction or an oxidation. (c) Structure D is that of beta-carotene, found in carrots. Suggest a reason for the importance of beta-carotene in the vision process.

- › influence of temperature on molecular speed and collision frequency (Section 5.5)

To survive a cold winter when food is scarce, some animals, such as deer mice, ground squirrels, and hedgehogs (*see photo*), sleep through! A hedgehog in hibernation drops its body temperature to 2–5°C to slow down its bodily functions, such as breathing rate (which is reduced to <2 breaths per minute), heart rate (decreases by 90%), and rates of metabolic reactions. At this slower pace, the hedgehog can conserve energy and survive with little food. When the weather is warmer, the life-sustaining processes increase in rate, and the animal goes about its business. Temperature, as you'll see, has a critical effect on the speed, or rate, of a reaction.

Until now, we haven't focused quantitatively on factors affecting reactions, other than the amounts of reactants and products and their molecular nature. Yet, while a balanced equation is essential for calculating yields, it tells us nothing about three dynamic aspects of chemical change:

- How fast is the reaction proceeding?
- How far will the reaction proceed toward completion?
- Will the reaction proceed by releasing energy or by absorbing it?

This chapter addresses the first of these questions and focuses on the field of *kinetics*. We'll address the other two questions in upcoming chapters. Answering all three is crucial to understanding modern technology, the environment, and the reactions in living things.

**IN THIS CHAPTER . . .** We examine the rate of a reaction, the factors that affect it, the theories that explain those effects, and the stepwise changes reactants undergo as they transform into products.

- › We introduce some general ideas about reaction rates and overview three key factors that affect them—concentration, physical state, and temperature.
- › We express rate through a rate law and determine its components.
- › We see how concentrations change as a reaction proceeds and discuss the meaning of reaction half-life.
- › To understand the effects of concentration and temperature on rate, we examine two related theories of chemical kinetics.
- › We discuss reaction mechanisms, noting the steps a reaction goes through and picturing the chemical species that exists as reactant bonds are breaking and product bonds are forming.
- › We see how catalysts increase reaction rates, highlighting two vital examples—the reactions in a living cell and the depletion of stratospheric ozone.

## 16.1 FOCUSING ON REACTION RATE

By definition, in a chemical reaction, reactants change into products. **Chemical kinetics**, the study of how fast that change occurs, focuses on the **reaction rate**, the change in the concentrations of reactants (or products) as a function of time. Different reactions have different rates: *in a faster reaction (higher rate), the reactant concentration decreases quickly, whereas in a slower reaction (lower rate), it decreases slowly* (Figure 16.1).

Chemical processes occur over a wide range of rates (Figure 16.2). Some—like a neutralization, a precipitation, or an explosion—may take a second or less. Processes that include many reactions—like the ripening of fruit—take days to months. Human aging continues for decades, and the formation of coal from dead plants takes

**Figure 16.1** A faster reaction (*top*) and a slower reaction (*bottom*). As time elapses, reactant *decreases* and product *increases*.

hundreds of millions of years. Knowing the reaction rate can be essential: how quickly a medicine acts can make the difference between life and death, and how long a commercial product takes to form can make the difference between profit and loss.

Under any given set of conditions, a rate is determined by the nature of the reactants. At room temperature, for example, hydrogen reacts explosively with fluorine but extremely slowly with nitrogen:

Furthermore, any given reaction has a different rate under different conditions.

We can control four factors that affect rate: the concentrations of reactants, their physical state, the temperature of the reaction, and the use of a catalyst. We consider the first three here and the fourth in Section 16.7.

1. *Concentration: molecules must collide to react.* A major factor influencing reaction rate is reactant concentration. Consider the reaction between ozone and nitrogen monoxide (nitric oxide):

This reaction occurs in the stratosphere, where the oxide is released in the exhaust gases of supersonic aircraft, but it can be simulated in the lab. In a reaction vessel, the molecules zoom every which way, crashing into each other and the vessel walls, but a reaction can occur only when NO and O<sub>3</sub> molecules collide. The more molecules present, the more frequently they collide, and the more often they react. Thus, *reaction rate is proportional to the number of collisions, which depends on the concentration of reactants*:

$$\text{Rate} \propto \text{collision frequency} \propto \text{concentration}$$

**Figure 16.2** The wide range of reaction rates.

2. *Physical state: molecules must mix to collide.* Collision frequency, and thus reaction rate, also depends on the physical state of the reactants, which determines how easily the reactants mix. When the reactants are in the same phase, as in an aqueous solution, random thermal motion brings them into contact, but gentle stirring mixes them further. When the reactants are in different phases, contact occurs only at the interface between the phases, so vigorous stirring or even grinding may be needed. Thus, *the more finely divided a solid or liquid reactant, the greater its surface area, the more contact it makes with the other reactant, and the faster the reaction occurs.* In Figure 16.3, a hot steel nail (*left*) placed in oxygen gas glows feebly, but the same mass of hot steel wool (*right*) bursts into flame. For the same reason, you start a campfire with twigs, not logs. The significant surface area of coal and grain dust in coal mines or grain elevators can cause massive explosions in the presence of an ignition source.

3. *Temperature: molecules must collide with enough energy.* Temperature usually has a major effect on the rate of a reaction. Two kitchen appliances employ this effect: a refrigerator slows down chemical processes that spoil food, whereas an oven speeds up other chemical processes that cook it. Temperature affects reaction rate by increasing the *frequency* and, more importantly, the *energy* of collisions:

- *Frequency of collisions.* Recall that molecules in a sample of gas have a range of speeds, with the most probable speed increasing with temperature (see Figure 5.14). Thus, *at a higher temperature, reactant particles move faster, collisions occur more frequently, and so more molecules react:*

$$\text{Rate} \propto \text{collision frequency} \propto \text{temperature}$$

- *Energy of collisions.* Even more important is that *temperature affects the kinetic energy* of the molecules. In the jumble of NO and O<sub>3</sub> molecules in the reaction vessel, most collisions have only enough energy for the molecules to bounce off each other without reacting. However, some collisions occur with sufficient energy for the molecules to react (Figure 16.4). *At a higher temperature, more sufficiently energetic collisions occur, and so more molecules react:*

$$\text{Rate} \propto \text{collision energy} \propto \text{temperature}$$

**Figure 16.4** Sufficient collision energy is required for a reaction to occur.

## › Summary of Section 16.1

- › Chemical kinetics focuses on reaction rate and the factors that affect it.
- › Under a given set of conditions, each reaction has its own rate.
- › Concentration affects rate by influencing the frequency of collisions between reactant molecules.
- › Physical state affects rate by determining how well reactants can mix.
- › Temperature affects rate by influencing the frequency and, more importantly, the energy of the collisions between reactant molecules.

Runners change positions with time.

## 16.2 EXPRESSING THE REACTION RATE

In general terms, a *rate* is a change in some variable per unit of time. The most familiar examples relate to speed (*see photo*), the change in position of an object divided by the change in time. For instance, if we measure a runner's initial position,  $x_1$ , at time  $t_1$ , and final position,  $x_2$ , at time  $t_2$ , the average speed is

$$\text{Rate of motion (speed)} = \frac{\text{change in position}}{\text{change in time}} = \frac{x_2 - x_1}{t_2 - t_1} = \frac{\Delta x}{\Delta t}$$

For the rate of a *reaction*, we measure the changes in concentrations of reactants or products per unit time: *reactant concentrations decrease while product concentrations increase* as the reaction proceeds. For the general reaction  $A \longrightarrow B$ , we measure the initial reactant concentration ( $A_1$ ) at  $t_1$ , allow the reaction to proceed, and then quickly measure the final reactant concentration ( $A_2$ ) at  $t_2$ . The change in concentration divided by the change in time gives the rate:

$$\text{Rate} = -\frac{\text{change in concentration of A}}{\text{change in time}} = -\frac{\text{conc } A_2 - \text{conc } A_1}{t_2 - t_1} = -\frac{\Delta(\text{conc } A)}{\Delta t}$$

The negative sign is important because, by convention, reaction rate is a *positive* number. But, since  $\text{conc } A_2$  must be *lower* than  $\text{conc } A_1$ , the *change in concentration (final – initial) of reactant A is negative*. Therefore, we use the negative sign to convert the negative change in reactant concentration to a positive value for the rate. Suppose the concentration of A changes from 1.2 mol/L ( $\text{conc } A_1$ ) to 0.75 mol/L ( $\text{conc } A_2$ ) over a 125-s period. The rate is

$$\text{Rate} = -\frac{0.75 \text{ mol/L} - 1.2 \text{ mol/L}}{125 \text{ s} - 0 \text{ s}} = 3.6 \times 10^{-3} \text{ mol/L} \cdot \text{s}$$

Square brackets, [ ], indicate a concentration in moles per liter (*molarity*). For example, [A] is the concentration of A in mol/L, and the rate expressed in terms of A is

$$\text{Rate} = -\frac{\Delta[A]}{\Delta t} \quad (16.1)$$

The units for the rate are moles per liter per second ( $\text{mol L}^{-1} \text{ s}^{-1}$ , or  $\text{mol/L} \cdot \text{s}$ ), or any time unit convenient for the reaction (minutes, years, and so on).

If instead we measure the *product* concentrations to determine the rate, we find that  $\text{conc } B_2$  is always *higher* than  $\text{conc } B_1$ . Thus, the *change in product concentration,  $\Delta[B]$ , is positive*, and the reaction rate for  $A \longrightarrow B$  expressed in terms of B is

$$\text{Rate} = +\frac{\Delta[B]}{\Delta t}$$

The plus sign is usually understood and not shown.

### Average, Instantaneous, and Initial Reaction Rates

In most cases, *the rate varies as a reaction proceeds*. Consider the reversible gas-phase reaction between ethylene and ozone, one of many reactions that may be involved in the formation of smog:

The equation shows that for every molecule of  $\text{C}_2\text{H}_4$  that reacts, a molecule of  $\text{O}_3$  reacts; thus,  $[\text{O}_3]$  and  $[\text{C}_2\text{H}_4]$  decrease at the same rate:

$$\text{Rate} = -\frac{\Delta[\text{C}_2\text{H}_4]}{\Delta t} = -\frac{\Delta[\text{O}_3]}{\Delta t}$$

When we start with a known  $[\text{O}_3]$  in a closed vessel at 30°C (303 K) and measure  $[\text{O}_3]$  at 10.0-s intervals during the first minute after adding  $\text{C}_2\text{H}_4$ , we obtain the concentration vs. time data shown in the table in Figure 16.5, which give the black curve. Note that

- The data points in Figure 16.5 result in a *curved* line, which means that the rate is changing over time (a straight line would mean that the rate was constant).

**Figure 16.5** Three types of reaction rates for the reaction of  $\text{O}_3$  and  $\text{C}_2\text{H}_4$ .

Time (s)	Concentration of $\text{O}_3$ (mol/L)
0.0	$3.20 \times 10^{-5}$
10.0	$2.42 \times 10^{-5}$
20.0	$1.95 \times 10^{-5}$
30.0	$1.63 \times 10^{-5}$
40.0	$1.40 \times 10^{-5}$
50.0	$1.23 \times 10^{-5}$
60.0	$1.10 \times 10^{-5}$

- The rate *decreases* during the course of the reaction because we are plotting *reactant* concentration vs. time: as  $\text{O}_3$  molecules react, fewer are present to collide with  $\text{C}_2\text{H}_4$  molecules, and the rate, the change in  $[\text{O}_3]$  over time, therefore decreases.

Three types of reaction rates are shown in the figure:

1. **Average rate.** Over a given period of time, the **average rate** is the slope of the line joining two points along the curve. The rate over the entire 60.0 s is the total change in concentration divided by the total change in time (Figure 16.5, line **a**):

$$\text{Rate} = -\frac{\Delta[\text{O}_3]}{\Delta t} = -\frac{(1.10 \times 10^{-5} \text{ mol/L}) - (3.20 \times 10^{-5} \text{ mol/L})}{60.0 \text{ s} - 0.0 \text{ s}} = 3.50 \times 10^{-7} \text{ mol/L}\cdot\text{s}$$

This quantity, which is the slope of line **a** (that is,  $\Delta[\text{O}_3]/\Delta t$ ), is the average rate over the entire period: during the first 60.0 s of the reaction,  $[\text{O}_3]$  decreases an *average* of  $3.50 \times 10^{-7}$  mol/L each second.

But, when you drive a car or ride a bike for a few miles, your speed over shorter distances may be lower or higher than your average speed. In the same sense, the decrease in  $[\text{O}_3]$  over the whole time period does not show the rate over any shorter time period. This *change* in reaction rate is evident when we calculate the average rate over two shorter periods. For the first 10.0 s, between 0.0 s and 10.0 s, the average rate (Figure 16.5, line **b**) is

$$\text{Rate} = -\frac{\Delta[\text{O}_3]}{\Delta t} = -\frac{(2.42 \times 10^{-5} \text{ mol/L}) - (3.20 \times 10^{-5} \text{ mol/L})}{10.0 \text{ s} - 0.0 \text{ s}} = 7.80 \times 10^{-7} \text{ mol/L}\cdot\text{s}$$

And, for the last 10.0 s, between 50.0 s and 60.0 s, the average rate (Figure 16.5, line **c**) is

$$\text{Rate} = -\frac{\Delta[\text{O}_3]}{\Delta t} = -\frac{(1.10 \times 10^{-5} \text{ mol/L}) - (1.23 \times 10^{-5} \text{ mol/L})}{60.0 \text{ s} - 50.0 \text{ s}} = 1.30 \times 10^{-7} \text{ mol/L}\cdot\text{s}$$

The reaction rate over the first 10.0 s is six times faster than the rate over the last 10.0 s.

2. **Instantaneous rate.** Since the average rate changes over a given time interval, it is more useful to know the **instantaneous rate**, the rate at a particular instant during the reaction. The shorter the time interval we consider, the closer we come to the instantaneous rate. As  $\Delta t$  becomes smaller and eventually approaches zero, we find

that *the instantaneous rate is the slope of a line tangent to the curve at time  $t$* . Therefore, in the terminology of calculus, the rate is the limit of the concentration change as  $\Delta t$  approaches zero, which equals the derivative of the concentration with respect to time:

$$\text{Rate} = \lim_{\Delta t \rightarrow 0} = -\frac{d[\text{C}_2\text{H}_4]}{dt} = -\frac{d[\text{O}_3]}{dt}$$

For example, the rate at 35.0 s is  $2.50 \times 10^{-7}$  mol/L·s, the slope of the line tangent to the curve through the point at  $t = 35.0$  s (Figure 16.5, line **d**). In general, we use the term *reaction rate* to mean *instantaneous reaction rate*.

3. *Initial rate.* The instantaneous rate at the moment the reactants are mixed (that is, at  $t = 0$ ) is the **initial rate**. We use this rate to avoid a complication: as a reaction proceeds in the *forward* direction (reactants  $\rightarrow$  products), product increases, causing the *reverse* reaction (reactants  $\leftarrow$  products), to occur more quickly. To find the overall (net) rate, we would have to calculate the difference between the forward and reverse rates. But, for the initial rate,  $t = 0$ , so product concentrations are negligible, and so is the reverse rate. We find the initial rate from the slope of the line tangent to the curve at  $t = 0$  s (Figure 16.5, line **e**). Since reactant concentrations are the largest at  $t = 0$ , the initial rate is faster than the instantaneous rate at *any* later time during the reaction. We typically use initial rates to find other kinetic parameters.

## Expressing Rate in Terms of Reactant and Product Concentrations

So far, for the reaction between  $\text{C}_2\text{H}_4$  and  $\text{O}_3$ , we've expressed the rate in terms of  $[\text{O}_3]$ , which is *decreasing*, and the rate would be expressed the same way in terms of  $[\text{C}_2\text{H}_4]$ . However, the rate is exactly the opposite in terms of the product concentrations because they are *increasing*. From the balanced equation, we see that one molecule each of  $\text{C}_2\text{H}_4\text{O}$  and of  $\text{O}_2$  appear for every molecule of  $\text{C}_2\text{H}_4$  and of  $\text{O}_3$  that disappear. Thus, we can express the rate in terms of any of the four substances:

$$\text{Rate} = -\frac{d[\text{C}_2\text{H}_4]}{dt} = -\frac{d[\text{O}_3]}{dt} = \frac{d[\text{C}_2\text{H}_4\text{O}]}{dt} = \frac{d[\text{O}_2]}{dt}$$

Figure 16.6A plots the changes in concentrations of one reactant ( $\text{C}_2\text{H}_4$ ) and one product ( $\text{O}_2$ ) simultaneously. The curves have the same shape but are inverted relative to each other, because, *for this reaction*, product appears at the same rate as reactant disappears, because of the 1/1 reactant/product molar ratio.

**Figure 16.6** Plots of [reactant] and [product] vs. time. **A**,  $\text{C}_2\text{H}_4$  and  $\text{O}_2$ . **B**,  $\text{H}_2$  and  $\text{HI}$ .

For many other reactions, though, reactants disappear and products appear at different rates. Consider the reaction between hydrogen and iodine to form hydrogen iodide:

From the balancing coefficients, we see that, for every molecule of  $\text{H}_2$  that disappears, one molecule of  $\text{I}_2$  disappears and *two* molecules of  $\text{HI}$  appear (the molar ratio of  $\text{H}_2/\text{HI}$  is  $1/2$ ). In other words, the rate of  $[\text{H}_2]$  decrease is the same as the rate of  $[\text{I}_2]$  decrease, but both are only half the rate of  $[\text{HI}]$  increase. Thus, in Figure 16.6B, the  $[\text{HI}]$  curve rises twice as fast as the  $[\text{H}_2]$  curve drops. If we refer the changes in  $[\text{I}_2]$  and  $[\text{HI}]$  to the change in  $[\text{H}_2]$ , we have

$$\text{Rate} = -\frac{d[\text{H}_2]}{dt} = -\frac{d[\text{I}_2]}{dt} = \frac{1}{2} \frac{d[\text{HI}]}{dt}$$

If, instead, we refer the changes in  $[\text{H}_2]$  and  $[\text{I}_2]$  to the change in  $[\text{HI}]$ , we obtain

$$\text{Rate} = \frac{d[\text{HI}]}{dt} = -2 \frac{d[\text{H}_2]}{dt} = -2 \frac{d[\text{I}_2]}{dt}$$

Note that this expression gives a rate that is double the previous one. Thus, *the expression for the rate of a reaction and its numerical value depend on which substance serves as the reference.*

We can summarize these results for any reaction,

where  $a$ ,  $b$ ,  $c$ , and  $d$  are coefficients of the balanced equation, as follows:

$$\text{Rate} = -\frac{1}{a} \frac{d[\text{A}]}{dt} = -\frac{1}{b} \frac{d[\text{B}]}{dt} = \frac{1}{c} \frac{d[\text{C}]}{dt} = \frac{1}{d} \frac{d[\text{D}]}{dt} \quad (16.2)$$

### SAMPLE PROBLEM 16.1

### Expressing Rate in Terms of Changes in Concentration with Time

**Problem** Hydrogen gas has a nonpolluting combustion product (water vapor). This gas is used as a fuel aboard the space shuttle and in earthbound cars with prototype engines:

- (a) Express the rate in terms of changes in  $[\text{H}_2]$ ,  $[\text{O}_2]$ , and  $[\text{H}_2\text{O}]$  with time.  
 (b) When  $[\text{O}_2]$  is decreasing at  $0.23 \text{ mol/L}\cdot\text{s}$ , at what rate is  $[\text{H}_2\text{O}]$  increasing?

**Plan** (a) Of the three substances in the equation, let's choose  $\text{O}_2$  as the reference because its coefficient is 1. For every molecule of  $\text{O}_2$  that disappears, two molecules of  $\text{H}_2$  disappear. Thus, the rate of  $[\text{O}_2]$  decrease is one-half the rate of  $[\text{H}_2]$  decrease. By similar reasoning, the rate of  $[\text{O}_2]$  decrease is one-half the rate of  $[\text{H}_2\text{O}]$  increase. (b) Because  $[\text{O}_2]$  is decreasing, the change in its concentration must be negative. We substitute the given rate as a negative value ( $-0.23 \text{ mol/L}\cdot\text{s}$ ) into the expression and solve for  $d[\text{H}_2\text{O}]/dt$ .

**Solution** (a) Expressing the rate in terms of each component:

$$\text{Rate} = -\frac{d[\text{O}_2]}{dt} = -\frac{1}{2} \frac{d[\text{H}_2]}{dt} = \frac{1}{2} \frac{d[\text{H}_2\text{O}]}{dt}$$

- (b) Calculating the rate of change of  $[\text{H}_2\text{O}]$ :

$$\begin{aligned} \frac{1}{2} \frac{d[\text{H}_2\text{O}]}{dt} &= -\frac{d[\text{O}_2]}{dt} = -(-0.23 \text{ mol/L}\cdot\text{s}) \\ \frac{d[\text{H}_2\text{O}]}{dt} &= 2(0.23 \text{ mol/L}\cdot\text{s}) = 0.46 \text{ mol/L}\cdot\text{s} \end{aligned}$$

**Check** (a) A good check is to use the rate expression to obtain the balanced equation:  $[\text{H}_2]$  changes twice as fast as  $[\text{O}_2]$ , so two  $\text{H}_2$  molecules react for each  $\text{O}_2$ .  $[\text{H}_2\text{O}]$  changes twice as fast as  $[\text{O}_2]$ , so two  $\text{H}_2\text{O}$  molecules form from each  $\text{O}_2$ . Thus, we get  $2\text{H}_2 + \text{O}_2 \longrightarrow 2\text{H}_2\text{O}$ . The values of  $[\text{H}_2]$  and  $[\text{O}_2]$  decrease, so they have negative

signs;  $[\text{H}_2\text{O}]$  increases, so it has a plus sign. Another check is to use Equation 16.2, with  $A = \text{H}_2$ ,  $a = 2$ ;  $B = \text{O}_2$ ,  $b = 1$ ; and  $C = \text{H}_2\text{O}$ ,  $c = 2$ :

$$\text{Rate} = -\frac{1}{a} \frac{d[A]}{dt} = -\frac{1}{b} \frac{d[B]}{dt} = \frac{1}{c} \frac{d[C]}{dt}$$

or

$$\text{Rate} = -\frac{1}{2} \frac{d[\text{H}_2]}{dt} = -\frac{d[\text{O}_2]}{dt} = \frac{1}{2} \frac{d[\text{H}_2\text{O}]}{dt}$$

(b) Given the rate expression, it makes sense that the numerical value of the rate of  $[\text{H}_2\text{O}]$  increase is twice that of  $[\text{O}_2]$  decrease.

**Comment** Thinking through this type of problem at the molecular level is the best approach, but use Equation 16.2 to confirm your answer.

### FOLLOW-UP PROBLEMS

*Brief Solutions for all Follow-up Problems appear at the end of the chapter.*

**16.1A** (a) Balance the following equation and express the rate in terms of the change in concentration with time for each substance:

(b) How fast is  $[\text{O}_2]$  decreasing when  $[\text{NO}]$  is decreasing at a rate of  $1.60 \times 10^{-4}$  mol/L·s?

**16.1B** For a particular reaction, the reaction rate in terms of the change in concentration with time for each substance is

$$\text{Rate} = -\frac{1}{4} \frac{d[\text{NH}_3]}{dt} = -\frac{1}{5} \frac{d[\text{O}_2]}{dt} = \frac{1}{4} \frac{d[\text{NO}]}{dt} = \frac{1}{6} \frac{d[\text{H}_2\text{O}]}{dt}$$

(a) Write a balanced equation for this gaseous reaction.

(b) When  $[\text{H}_2\text{O}]$  is increasing at a rate of  $2.52 \times 10^{-2}$  mol/L·s, how fast is  $[\text{O}_2]$  decreasing?

**SOME SIMILAR PROBLEMS** 16.14–16.19

## › Summary of Section 16.2

- › The average reaction rate is the change in reactant (or product) concentration over a change in time,  $\Delta t$ . The rate slows as the reaction proceeds because reactants are used up.
- › The instantaneous rate at time  $t$  is the slope of the tangent to a curve that plots concentration vs. time, and equals  $-d[A]/dt$ .
- › The initial rate, the instantaneous rate at  $t = 0$ , occurs when reactants have just been mixed and before any product accumulates.
- › The expression for a reaction rate and its numerical value depend on which reaction component is being referenced.

## 16.3 THE RATE LAW AND ITS COMPONENTS

The centerpiece of any kinetic study of a reaction is the **rate law** (or **rate equation**), which expresses the rate as a function of concentrations and temperature. The rate law is based on experiment, so any hypothesis about how the reaction occurs on the molecular level must conform to it.

In this discussion, we generally consider reactions for which the products do not appear in the rate law, so the rate depends only on *reactant* concentrations and temperature. For a general reaction occurring at a fixed temperature,

the rate law is

$$\text{Rate} = k[\text{A}]^m[\text{B}]^n \dots \quad (16.3)$$

The term  $k$  is a proportionality constant, called the **rate constant**, that is specific for a given reaction at a given temperature and does *not* change as the reaction proceeds. (As we'll see in Section 16.5,  $k$  *does* change with temperature.) The exponents  $m$  and  $n$ ,

called the **reaction orders**, define how the rate is affected by reactant concentration; we'll see how to determine them shortly. Two key points to remember are

- The balancing coefficients  $a$  and  $b$  in the reaction equation are **not** necessarily related in any way to the reaction orders  $m$  and  $n$ .
- The components of the rate law—rate, reaction orders, and rate constant—**must** be found by experiment.

In the remainder of this section, we'll find the components of the rate law by measuring concentrations to determine the *initial rate*, using initial rates to determine the *reaction orders*, and using these values to calculate the *rate constant*. With the rate law for a reaction, we can predict the rate for any initial concentrations.

## Some Laboratory Methods for Determining the Initial Rate

We determine an initial rate from a plot of concentration vs. time, so we need a quick, accurate method for measuring concentration as a reaction proceeds. Let's briefly discuss three common approaches.

1. *Spectrometric methods* measure the concentration of a component that absorbs (or emits) characteristic wavelengths of light. For example, in the reaction of NO and O<sub>3</sub>, only NO<sub>2</sub> has a color (an indication that NO<sub>2</sub> absorbs some wavelength of visible light):

Known amounts of reactants are injected into a tube of known volume within a spectrometer (see Tools of the Laboratory, end of Section 7.2), which is set to measure the wavelength and intensity of the color. The rate of NO<sub>2</sub> formation is proportional to the increase in that intensity over time.

2. *Conductometric methods* rely on the change in electrical conductivity of the reaction solution when nonionic reactants form ionic products, or vice versa. Consider the substitution reaction between a haloalkane, such as 2-bromo-2-methylpropane, and water:

The HBr that forms is a strong acid, so it dissociates completely in the water. As time passes, more ions form, so the conductivity of the reaction mixture increases.

3. *Manometric methods* employ a manometer attached to a reaction vessel of fixed volume and temperature. The manometer measures the pressure change in the vessel due to a reaction that involves a change in the number of moles of gas. Consider the decomposition reaction of hydrogen peroxide:

The rate is directly proportional to the increase in pressure as O<sub>2</sub> gas forms.

## Determining Reaction Orders

With the initial rate in hand, we can determine reaction orders. Let's first discuss what reaction orders are and then see how to determine them by controlling reactant concentrations.

**First, Second, and Zero Orders** A reaction has an *individual* order “with respect to” or “in” each reactant, and an *overall* order, the sum of the individual orders.

Consider first the simplest case, a reaction with only one reactant, A:

- *First order.* If the rate doubles when [A] doubles, the rate depends on [A] raised to the first power, [A]<sup>1</sup> (the superscript 1 is generally omitted). Thus, the reaction is *first order* in (or with respect to) A and *first order* overall:

$$\text{Rate} = k[\text{A}]^1 = k[\text{A}]$$

- *Second order.* If the rate quadruples when [A] doubles, the rate depends on [A] squared, [A]<sup>2</sup>. In this case, the reaction is *second order* in A and *second order* overall:

$$\text{Rate} = k[\text{A}]^2$$

**Figure 16.7** Plots of reactant concentration,  $[A]$ , vs. time for first-, second-, and zero-order reactions.

**Figure 16.8** Plots of rate vs. reactant concentration,  $[A]$ , for first-, second-, and zero-order reactions.

- **Zero order.** If the rate does not change when  $[A]$  doubles, the rate does *not* depend on  $[A]$ , but we express this fact mathematically by saying that the rate depends on  $[A]$  raised to the zero power,  $[A]^0$ . The reaction is *zero order* in  $A$  and *zero order* overall:

$$\text{Rate} = k[A]^0 = k(1) = k$$

Figure 16.7 shows plots of  $[A]$  vs. time for first-, second-, and zero-order reactions. (In all cases, the value of  $k$  was assumed to be the same.) Notice that

- The decrease in  $[A]$  doesn't change as time goes on for a zero-order reaction; the rate is constant.
- The decrease slows down as time goes on for a first-order reaction.
- The decrease slows even more for a second-order reaction.

These results are reflected in Figure 16.8, which shows plots of rate vs.  $[A]$  for the same reaction orders. Notice that

- The plot is a horizontal line for the zero-order reaction because the rate doesn't change regardless of the value of  $[A]$ .
- The plot is an upward-sloping *line* for the first-order reaction because the rate is directly proportional to  $[A]$ .
- The plot is an upward-sloping *curve* for the second-order reaction because the rate increases exponentially with  $[A]$ .

Let's look at some examples of observed rate laws and note the reaction orders.

1. For the reaction between nitrogen monoxide and ozone,

the rate law is

$$\text{Rate} = k[\text{NO}][\text{O}_3]$$

This reaction is first order with respect to  $\text{NO}$  and first order with respect to  $\text{O}_3$ , so it is second order overall ( $1 + 1 = 2$ ).

2. For the hydrolysis of 2-bromo-2-methylpropane,

the rate law is

$$\text{Rate} = k[(\text{CH}_3)_3\text{CBr}]$$

This reaction is first order in 2-bromo-2-methylpropane and zero order with respect to  $\text{H}_2\text{O}$ , *despite its coefficient of 1 in the balanced equation*. If we want to note that water is a reactant, we can write

$$\text{Rate} = k[(\text{CH}_3)_3\text{CBr}][\text{H}_2\text{O}]^0$$

Overall, this is a first-order reaction ( $1 + 0 = 1$ ).

3. Finally, for the reaction between  $\text{NO}$  and hydrogen gas,

the rate law is

$$\text{Rate} = k[\text{NO}]^2[\text{H}_2]$$

This reaction is second order in  $\text{NO}$ . And even though  $\text{H}_2$  has a coefficient of 2 in the balanced equation, the reaction is *first order* in  $\text{H}_2$ . It is third order overall ( $2 + 1 = 3$ ).

These examples reiterate an important point: *reaction orders cannot be deduced from the balanced equation but must be determined from experimental data*.

The larger the reaction order for a reactant, the greater the effect the concentration of that reactant has on the rate. For example, consider the result of doubling both  $[\text{NO}]$  and  $[\text{H}_2]$  in the third reaction discussed above:

$$\text{Rate} = k[\text{NO}]^2[\text{H}_2] = k(2)^2(2) = k \times 4 \times 2 = k \times 8, \text{ or } 8k$$

Since the change in  $[\text{NO}]$  is squared, doubling  $[\text{NO}]$  results in the rate increasing by a factor of 4, while doubling  $[\text{H}_2]$  increases the rate only by a factor of 2; the net effect of the change in both concentrations is that the rate increases by a factor of 8.

**Other Reaction Orders** Although usually positive integers or zero, reaction orders can also be fractional or negative.

1. For the reaction

a fractional order appears in the rate law:

$$\text{Rate} = k[\text{CHCl}_3][\text{Cl}_2]^{1/2}$$

This *fractional reaction order* means that if, for example,  $[\text{Cl}_2]$  increases by a factor of 4, the rate increases by a factor of 2, the square root of the change in  $[\text{Cl}_2]$ , or  $(4)^{1/2}$ . The overall order of this reaction is  $1 + \frac{1}{2} = \frac{3}{2}$ .

2. A *negative reaction order* means the rate *decreases* when the concentration of that component increases. Negative orders are often seen when the rate law includes products. For example, for the atmospheric reaction

the rate law is

$$\text{Rate} = k[\text{O}_3]^2[\text{O}_2]^{-1} = k \frac{[\text{O}_3]^2}{[\text{O}_2]}$$

If  $[\text{O}_2]$  doubles, the reaction proceeds half as fast. This reaction is second order in  $\text{O}_3$  and negative first order in  $\text{O}_2$ , so it is first order overall  $[2 + (-1) = 1]$ .

### SAMPLE PROBLEM 16.2

### Determining Reaction Orders from Rate Laws

**Problem** For each of the following reactions, use the given rate law to determine the reaction order with respect to each reactant and the overall order; for the reaction in (a), determine the factor by which the rate changes if  $[\text{NO}]$  is tripled and  $[\text{O}_2]$  is doubled.

**Plan** We inspect the exponents in the rate law, *not* the coefficients of the balanced equation, to find the individual orders, and then take their sum to find the overall reaction order. To find the change in rate for the reaction in (a), we substitute 3 for  $[\text{NO}]$  in the rate law (since that concentration changes by a factor of 3) and 2 for  $[\text{O}_2]$  (since that concentration changes by a factor of 2), and solve for the rate.

**Solution** (a) The exponent of  $[\text{NO}]$  is 2, so the reaction is second order with respect to  $\text{NO}$ , first order with respect to  $\text{O}_2$ , and third order overall.

Finding the change in rate:

$$\text{Rate} = k[\text{NO}]^2[\text{O}_2] = k(3)^2(2) = k \times 18 = 18k$$

The rate increases by a factor of 18.

(b) The reaction is  $\frac{3}{2}$  order in  $\text{CH}_3\text{CHO}$  and  $\frac{3}{2}$  order overall.

(c) The reaction is first order in  $\text{H}_2\text{O}_2$ , first order in  $\text{I}^-$ , and second order overall.

The reactant  $\text{H}^+$  does not appear in the rate law, so the reaction is zero order in  $\text{H}^+$ .

**Check** Be sure that each reactant has an order and that the sum of the individual orders gives the overall order. For the rate change in (a), be sure that the 3 used to indicate a tripled concentration is squared since the reaction is second order in  $\text{NO}$ .

### FOLLOW-UP PROBLEMS

**16.2A** Experiment shows that the reaction

obeys this rate law: rate =  $k[\text{I}^-][\text{BrO}_3^-][\text{H}^+]^2$ . (a) What is the reaction order in each reactant and the overall reaction order? (b) By what factor does the rate change if  $[\text{I}^-]$  and  $[\text{BrO}_3^-]$  are tripled and  $[\text{H}^+]$  is doubled?

**16.2B** The rate law for the reaction

is rate =  $k[\text{ClO}_2]^2[\text{OH}^-]$ . (a) What is the reaction order in each reactant and the overall reaction order? (b) By what factor does the rate change if  $[\text{ClO}_2]$  is halved and  $[\text{OH}^-]$  is doubled?

**SOME SIMILAR PROBLEMS** 16.26–16.33

**Determining Reaction Orders by Changing Reactant Concentrations** Now let's see how reaction orders are found *before* the rate law is known. Before looking at a real reaction, we'll go through the process for substances A and B in this reaction:

The rate law, expressed in general terms, is

$$\text{Rate} = k[\text{A}]^m[\text{B}]^n$$

To find the values of  $m$  and  $n$ , we run a series of experiments in which one reactant concentration changes while the other is kept constant, and we measure the effect on the initial rate in each case. Table 16.1 shows the results.

**Table 16.1****Initial Rates for the Reaction Between A and B**

Experiment	Initial Rate (mol/L·s)	Initial [A] (mol/L)	Initial [B] (mol/L)
1	$1.75 \times 10^{-3}$	$2.50 \times 10^{-2}$	$3.00 \times 10^{-2}$
2	$3.50 \times 10^{-3}$	$5.00 \times 10^{-2}$	$3.00 \times 10^{-2}$
3	$3.50 \times 10^{-3}$	$2.50 \times 10^{-2}$	$6.00 \times 10^{-2}$
4	$7.00 \times 10^{-3}$	$5.00 \times 10^{-2}$	$6.00 \times 10^{-2}$

1. *Finding  $m$ , the order with respect to A.* By comparing experiments 1 and 2, in which [A] doubles and [B] is constant, we can obtain  $m$ . First, we take the ratio of the general rate laws for these two experiments:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{k[\text{A}]_2^m[\text{B}]_2^n}{k[\text{A}]_1^m[\text{B}]_1^n}$$

where  $[\text{A}]_2$  is the concentration of A in experiment 2,  $[\text{B}]_1$  is the concentration of B in experiment 1, and so forth. Because  $k$  is a constant and [B] does not change between these two experiments, those quantities cancel:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{k[\text{A}]_2^m[\text{B}]_2^n}{k[\text{A}]_1^m[\text{B}]_1^n} = \frac{[\text{A}]_2^m}{[\text{A}]_1^m} = \left(\frac{[\text{A}]_2}{[\text{A}]_1}\right)^m$$

Substituting the values from Table 16.1, we have

$$\frac{3.50 \times 10^{-3} \text{ mol/L}\cdot\text{s}}{1.75 \times 10^{-3} \text{ mol/L}\cdot\text{s}} = \left(\frac{5.00 \times 10^{-2} \text{ mol/L}}{2.50 \times 10^{-2} \text{ mol/L}}\right)^m$$

Dividing, we obtain

$$2.00 = (2.00)^m \quad \text{so} \quad m = 1$$

Thus, the reaction is first order in A, because when [A] doubles, the rate doubles.

2. *Finding  $n$ , the order with respect to B.* To find  $n$ , we compare experiments 3 and 1 in which [A] is held constant and [B] doubles:

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{k[\text{A}]_3^m[\text{B}]_3^n}{k[\text{A}]_1^m[\text{B}]_1^n}$$

As before,  $k$  is a constant, and in this pair of experiments, [A] does not change, so those quantities cancel, and we have

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{k[\text{A}]_3^m[\text{B}]_3^n}{k[\text{A}]_1^m[\text{B}]_1^n} = \frac{[\text{B}]_3^n}{[\text{B}]_1^n} = \left(\frac{[\text{B}]_3}{[\text{B}]_1}\right)^n$$

The actual values give

$$\frac{3.50 \times 10^{-3} \text{ mol/L}\cdot\text{s}}{1.75 \times 10^{-3} \text{ mol/L}\cdot\text{s}} = \left( \frac{6.00 \times 10^{-2} \text{ mol/L}}{3.00 \times 10^{-2} \text{ mol/L}} \right)^n$$

Dividing, we obtain

$$2.00 = (2.00)^n \quad \text{so} \quad n = 1$$

Thus, the reaction is also first order in B because when [B] doubles, the rate doubles. We can check this conclusion from experiments 1 and 4: when *both* [A] and [B] double, the rate should quadruple, and it does. Thus, the rate law, with *m* and *n* equal to 1, is

$$\text{Rate} = k[\text{A}][\text{B}]$$

Note, especially, that while the order with respect to B is 1, the coefficient of B in the balanced equation is 2. Thus, as we said earlier, *reaction orders must be determined from experiment*, not from the balanced equation.

Next, let's go through this process for a real reaction, the one between oxygen and nitrogen monoxide, a key step in the formation of acid rain and in the industrial production of nitric acid:

The general rate law is

$$\text{Rate} = k[\text{O}_2]^m[\text{NO}]^n$$

Table 16.2 shows experiments that change one reactant concentration while keeping the other constant.

**Table 16.2**

**Initial Rates for the Reaction Between O<sub>2</sub> and NO**

Experiment	Initial Rate (mol/L·s)	Initial Reactant Concentrations (mol/L)	
		[O <sub>2</sub> ]	[NO]
1	3.21 × 10 <sup>-3</sup>	1.10 × 10 <sup>-2</sup>	1.30 × 10 <sup>-2</sup>
2	6.40 × 10 <sup>-3</sup>	2.20 × 10 <sup>-2</sup>	1.30 × 10 <sup>-2</sup>
3	12.8 × 10 <sup>-3</sup>	1.10 × 10 <sup>-2</sup>	2.60 × 10 <sup>-2</sup>
4	9.60 × 10 <sup>-3</sup>	3.30 × 10 <sup>-2</sup>	1.30 × 10 <sup>-2</sup>
5	28.8 × 10 <sup>-3</sup>	1.10 × 10 <sup>-2</sup>	3.90 × 10 <sup>-2</sup>

1. *Finding m, the order with respect to O<sub>2</sub>.* If we compare experiments 1 and 2, in which [O<sub>2</sub>] doubles and [NO] is constant, we see the effect of doubling [O<sub>2</sub>] on the rate. First, we take the ratio of their rate laws:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{k[\text{O}_2]_2^m [\text{NO}]_2^n}{k[\text{O}_2]_1^m [\text{NO}]_1^n}$$

As before, the constant quantities—*k* and [NO]—cancel:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{k [\text{O}_2]_2^m [\text{NO}]_2^n}{k [\text{O}_2]_1^m [\text{NO}]_1^n} = \frac{[\text{O}_2]_2^m}{[\text{O}_2]_1^m} = \left( \frac{[\text{O}_2]_2}{[\text{O}_2]_1} \right)^m$$

Substituting the values from Table 16.2, we obtain

$$\frac{6.40 \times 10^{-3} \text{ mol/L}\cdot\text{s}}{3.21 \times 10^{-3} \text{ mol/L}\cdot\text{s}} = \left( \frac{2.20 \times 10^{-2} \text{ mol/L}}{1.10 \times 10^{-2} \text{ mol/L}} \right)^m$$

Dividing, we obtain

$$1.99 = (2.00)^m$$

Rounding to one significant figure gives

$$2 = 2^m, \quad \text{so} \quad m = 1$$

Sometimes, the exponent is not as easy to find by inspection as it is here. In those cases, we solve for *m* with an equation of the form  $a = b^m$ , which in this case gives

$$\log a = m \log b \quad \text{or} \quad m = \frac{\log a}{\log b} = \frac{\log 1.99}{\log 2.00} = 0.993$$

which rounds to 1. Thus, the reaction is first order in  $O_2$ : when  $[O_2]$  doubles, the rate doubles.

2. *Finding  $n$ , the order with respect to NO.* We compare experiments 3 and 1, in which  $[O_2]$  is held constant and  $[NO]$  is doubled, to find the order of NO:

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{k[O_2]_3^m [NO]_3^n}{k[O_2]_1^m [NO]_1^n}$$

Canceling the constant  $k$  and the unchanging  $[O_2]$ , we have

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{k [O_2]_3^m [NO]_3^n}{k [O_2]_1^m [NO]_1^n} = \frac{[NO]_3^n}{[NO]_1^n} = \left( \frac{[NO]_3}{[NO]_1} \right)^n$$

The actual values give

$$\frac{12.8 \times 10^{-3} \text{ mol/L}\cdot\text{s}}{3.21 \times 10^{-3} \text{ mol/L}\cdot\text{s}} = \left( \frac{2.60 \times 10^{-2} \text{ mol/L}}{1.30 \times 10^{-2} \text{ mol/L}} \right)^n$$

Dividing, we obtain

$$3.99 = (2.00)^n$$

Solving for  $n$ :

$$n = \frac{\log 3.99}{\log 2.00} = 2.00 \quad (\text{or } 2)$$

The reaction is second order in NO: when  $[NO]$  doubles, the rate quadruples. Thus, the actual rate law is

$$\text{Rate} = k[O_2][NO]^2$$

In this case, the reaction orders happen to be the same as the equation coefficients; nevertheless, they must *always* be determined by experiment.

## Determining the Rate Constant

Let's find the rate constant for the reaction of  $O_2$  and NO. With the rate, reactant concentrations, and reaction orders known, the sole remaining unknown in the rate law is the rate constant,  $k$ . We can use data from *any* of the experiments in Table 16.2 to solve for  $k$ . From experiment 1, for instance, we have

$$\begin{aligned} \text{Rate} &= k[O_2]_1[NO]_1^2 \\ k &= \frac{\text{rate 1}}{[O_2]_1[NO]_1^2} = \frac{3.21 \times 10^{-3} \text{ mol/L}\cdot\text{s}}{(1.10 \times 10^{-2} \text{ mol/L})(1.30 \times 10^{-2} \text{ mol/L})^2} \\ &= \frac{3.21 \times 10^{-3} \text{ mol/L}\cdot\text{s}}{1.86 \times 10^{-6} \text{ mol}^3/\text{L}^3} = 1.73 \times 10^3 \text{ L}^2/\text{mol}^2\cdot\text{s} \end{aligned}$$

Always check that the values of  $k$  for a series of experiments are constant within experimental error. To three significant figures, the average value of  $k$  for the five experiments in Table 16.2 is  $1.72 \times 10^3 \text{ L}^2/\text{mol}^2\cdot\text{s}$ .

With concentrations in mol/L and the reaction rate in units of mol/L·time, the units for  $k$  depend on the order of the reaction and, of course, the time unit. For this reaction, the units for  $k$  have to be  $\text{L}^2/\text{mol}^2\cdot\text{s}$  to give a rate with units of mol/L·s:

$$\begin{aligned} \text{Rate} &= k[O_2][NO]^2 \\ \frac{\text{mol}}{\text{L}\cdot\text{s}} &= \frac{\text{L}^2}{\text{mol}^2\cdot\text{s}} \times \frac{\text{mol}}{\text{L}} \times \left( \frac{\text{mol}}{\text{L}} \right)^2 \end{aligned}$$

The rate constant will *always* have these units for an overall third-order reaction with the time unit of seconds. Table 16.3 shows the units of  $k$  for common integer overall orders, but you can always determine the units mathematically.

Figure 16.9 summarizes the steps for studying the kinetics of a reaction. The next two sample problems offer practice in applying this approach; the first is based on data and the second on molecular scenes.

### Student Hot Spot

Student data indicate that you may struggle with determining reaction orders by changing reactant concentrations. Access the Smartbook to view additional Learning Resources on this topic.

Table 16.3

Units of the Rate Constant  $k$  for Several Overall Reaction Orders

Overall Reaction Order	Units of $k$ (t in seconds)
0	mol/L·s (or mol L <sup>-1</sup> s <sup>-1</sup> )
1	1/s (or s <sup>-1</sup> )
2	L/mol·s (or L mol <sup>-1</sup> s <sup>-1</sup> )
3	L <sup>2</sup> /mol <sup>2</sup> ·s (or L <sup>2</sup> mol <sup>-2</sup> s <sup>-1</sup> )

General formula:

$$\text{Units of } k = \frac{\left( \frac{\text{L}}{\text{mol}} \right)^{\text{order}-1}}{\text{unit of } t}$$

Figure 16.9 Information sequence to determine the kinetic parameters of a reaction.

### SAMPLE PROBLEM 16.3

### Determining Reaction Orders and Rate Constants from Rate Data

**Problem** Many gaseous reactions occur in car engines and exhaust systems. One of these is

- (a) Use the following data to determine the individual and overall reaction orders.  
 (b) Calculate  $k$  using the data from experiment 1.

Experiment	Initial Rate (mol/L·s)	Initial [NO <sub>2</sub> ] (mol/L)	Initial [CO] (mol/L)
1	0.0050	0.10	0.10
2	0.080	0.40	0.10
3	0.0050	0.10	0.20

**Plan** (a) We need to solve the general rate law for  $m$  and for  $n$  and then add those orders to get the overall order. To solve for each exponent, we proceed as in the text, taking the ratio of the rate laws for two experiments in which only the reactant in question changes. (b) We substitute the values for the rate and the reactant concentrations from experiment 1 into the rate law and solve for  $k$ .

**Solution** (a) Calculating  $m$  in  $[\text{NO}_2]^m$ : We take the ratio of the rate laws for experiments 1 and 2, in which  $[\text{NO}_2]$  varies but  $[\text{CO}]$  is constant:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{k[\text{NO}_2]_2^m[\text{CO}]_2^n}{k[\text{NO}_2]_1^m[\text{CO}]_1^n} = \left(\frac{[\text{NO}_2]_2}{[\text{NO}_2]_1}\right)^m \quad \text{or} \quad \frac{0.080 \text{ mol/L}\cdot\text{s}}{0.0050 \text{ mol/L}\cdot\text{s}} = \left(\frac{0.40 \text{ mol/L}}{0.10 \text{ mol/L}}\right)^m$$

This gives  $16 = (4.0)^m$ , so we have  $m = \log 16 / \log 4.0 = 2.0$ . The reaction is **second order in NO<sub>2</sub>**.

Calculating  $n$  in  $[\text{CO}]^n$ : We take the ratio of the rate laws for experiments 1 and 3, in which  $[\text{CO}]$  varies but  $[\text{NO}_2]$  is constant:

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{k[\text{NO}_2]_3^m[\text{CO}]_3^n}{k[\text{NO}_2]_1^m[\text{CO}]_1^n} = \left(\frac{[\text{CO}]_3}{[\text{CO}]_1}\right)^n \quad \text{or} \quad \frac{0.0050 \text{ mol/L}\cdot\text{s}}{0.0050 \text{ mol/L}\cdot\text{s}} = \left(\frac{0.20 \text{ mol/L}}{0.10 \text{ mol/L}}\right)^n$$

We have  $1.0 = (2.0)^n$ , so  $n = 0$ . The rate does not change when  $[\text{CO}]$  varies, so the reaction is **zero order in CO**.

Therefore, the rate law is

$$\text{Rate} = k[\text{NO}_2]^2[\text{CO}]^0 = k[\text{NO}_2]^2(1) = k[\text{NO}_2]^2$$

The reaction is **second order overall**.

- (b) From experiment 1, rate = 0.0050 mol/L·s and  $[\text{NO}_2] = 0.10$  mol/L. Calculating  $k$ :

$$\begin{aligned} \text{Rate} &= k[\text{NO}_2]^2 \\ k &= \frac{\text{Rate}}{[\text{NO}_2]^2} = \frac{0.0050 \text{ mol/L}\cdot\text{s}}{(0.10 \text{ mol/L})^2} \\ &= 0.50 \text{ L/mol}\cdot\text{s} \end{aligned}$$

**Check** A good check is to reason through the orders. If  $m = 1$ , quadrupling  $[\text{NO}_2]$  would quadruple the rate; but the rate *more* than quadruples, so  $m > 1$ . If  $m = 2$ , quadrupling  $[\text{NO}_2]$  would increase the rate by a factor of 16 ( $4^2$ ). The ratio of rates is  $0.080/0.005 = 16$ , so  $m = 2$ . In contrast, increasing  $[\text{CO}]$  has no effect on the rate, which can happen only if  $[\text{CO}]^n = 1$ , so  $n = 0$ . The calculated value for the rate constant can be verified using the data from experiments 2 and 3.

## FOLLOW-UP PROBLEMS

**16.3A** Find the rate law, the individual and overall reaction orders, and the average value of  $k$  for the reaction  $\text{H}_2 + \text{I}_2 \longrightarrow 2\text{HI}$ , using the following data at  $450^\circ\text{C}$ :

Experiment	Initial Rate (mol/L·s)	Initial $[\text{H}_2]$ (mol/L)	Initial $[\text{I}_2]$ (mol/L)
1	$1.9 \times 10^{-23}$	0.0113	0.0011
2	$1.1 \times 10^{-22}$	0.0220	0.0033
3	$9.3 \times 10^{-23}$	0.0550	0.0011
4	$1.9 \times 10^{-22}$	0.0220	0.0056

**16.3B** For the reaction  $\text{H}_2\text{SeO}_3(\text{aq}) + 6\text{I}^-(\text{aq}) + 4\text{H}^+(\text{aq}) \longrightarrow \text{Se}(\text{s}) + 2\text{I}_3^-(\text{aq}) + 3\text{H}_2\text{O}(\text{l})$  at  $0^\circ\text{C}$ , the following data were obtained:

Experiment	Initial Rate (mol/L·s)	Initial $[\text{H}_2\text{SeO}_3]$ (mol/L)	Initial $[\text{I}^-]$ (mol/L)	Initial $[\text{H}^+]$ (mol/L)
1	$9.85 \times 10^{-7}$	$2.5 \times 10^{-3}$	$1.5 \times 10^{-2}$	$1.5 \times 10^{-2}$
2	$7.88 \times 10^{-6}$	$2.5 \times 10^{-3}$	$3.0 \times 10^{-2}$	$1.5 \times 10^{-2}$
3	$3.94 \times 10^{-6}$	$1.0 \times 10^{-2}$	$1.5 \times 10^{-2}$	$1.5 \times 10^{-2}$
4	$3.15 \times 10^{-5}$	$2.5 \times 10^{-3}$	$3.0 \times 10^{-2}$	$3.0 \times 10^{-2}$

- (a) Find the rate law for the reaction.  
 (b) Find the value of  $k$  (using the data in experiment 1).

**SOME SIMILAR PROBLEMS** 16.34, 16.35, and 16.38

## SAMPLE PROBLEM 16.4

## Determining Reaction Orders from Molecular Scenes

**Problem** At a particular temperature and volume, two gases, A (*red*) and B (*blue*), react. The following molecular scenes represent starting mixtures for four experiments:

Expt no.:	1	2	3	4
Initial rate (mol/L·s):	$0.50 \times 10^{-4}$	$1.0 \times 10^{-4}$	$2.0 \times 10^{-4}$	?

- (a) What is the reaction order with respect to A? With respect to B? The overall order?  
 (b) Write the rate law for the reaction.  
 (c) Predict the initial rate of Expt 4.

**Plan** (a) As before, we find the individual reaction orders by seeing how a change in each reactant changes the rate. In this case, however, instead of using concentration data, we count numbers of particles. The sum of the individual orders is the overall order. (b) To write the rate law, we use the orders from part (a) as exponents in the general rate law. (c) Using the results from Expts 1 through 3 and the rate law from part (b), we find the unknown initial rate of Expt 4.

**Solution** (a) The rate law is  $\text{rate} = k[\text{A}]^m[\text{B}]^n$ . For reactant A (*red*) in Expts 1 and 2 ( $k$  and number of B particles are constant):

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{k[\text{A}]_2^m[\text{B}]_2^n}{k[\text{A}]_1^m[\text{B}]_1^n} = \left(\frac{[\text{A}]_2}{[\text{A}]_1}\right)^m \quad \text{or} \quad \frac{1.0 \times 10^{-4} \text{ mol/L}\cdot\text{s}}{0.50 \times 10^{-4} \text{ mol/L}\cdot\text{s}} = \left(\frac{4 \text{ particles}}{2 \text{ particles}}\right)^m$$

Thus,  $2 = (2)^m$  so the order with respect to A is 1. For reactant B (*blue*) in Expts 1 and 3 ( $k$  and number of A particles are constant):

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{k[\text{A}]_3^m[\text{B}]_3^n}{k[\text{A}]_1^m[\text{B}]_1^n} = \left(\frac{[\text{B}]_3}{[\text{B}]_1}\right)^n \quad \text{or} \quad \frac{2.0 \times 10^{-4} \text{ mol/L}\cdot\text{s}}{0.50 \times 10^{-4} \text{ mol/L}\cdot\text{s}} = \left(\frac{4 \text{ particles}}{2 \text{ particles}}\right)^n$$

Thus,  $4 = (2)^n$  so the order with respect to B is 2. The overall order is  $1 + 2 = 3$ .

(b) Writing the rate law: The general rate law is  $\text{rate} = k[\text{A}]^m[\text{B}]^n$ , so we have

$$\text{Rate} = k[\text{A}][\text{B}]^2$$

(c) Finding the initial rate of Expt 4: There are several possibilities, but let's compare Expts 3 and 4, in which the number of particles of A doubles (from 2 to 4) and the number of particles of B doesn't change. Since the rate law shows that the reaction is first order in A, the initial rate in Expt 4 should be double the initial rate in Expt 3, or  $4.0 \times 10^{-4} \text{ mol/L}\cdot\text{s}$ .

**Check** A good check is to compare other pairs of experiments. (a) Comparing Expts 2 and 3 shows that the number of B doubles, which causes the rate to quadruple, and the number of A decreases by half, which causes the rate to halve; so the overall rate change should double (from  $1.0 \times 10^{-4} \text{ mol/L}\cdot\text{s}$  to  $2.0 \times 10^{-4} \text{ mol/L}\cdot\text{s}$ ), which it does.

(c) Comparing Expts 2 and 4, in which the number of A is constant and the number of B doubles, the rate should quadruple, which means the initial rate of Expt 4 would be  $4.0 \times 10^{-4} \text{ mol/L}\cdot\text{s}$ , as we found.

### FOLLOW-UP PROBLEMS

**16.4A** The molecular scenes below show three experiments at a given temperature and volume involving reactants X (black) and Y (green):

If the rate law for the reaction is  $\text{rate} = k[\text{X}]^2$ : (a) What is the initial rate of Expt 2?

(b) Draw a scene for Expt 3 that involves a single change of the scene for Expt 1.

**16.4B** The scenes below show mixtures of reactants A (blue) and B (yellow) at a given temperature and volume:

(a) Write the rate law for the reaction.

(b) How many particles of A should be shown in the scene for Expt 4?

**SOME SIMILAR PROBLEMS** 16.93, 16.122(a), and 16.122(b)

## › Summary of Section 16.3

- › An experimentally determined rate law shows how the rate of a reaction depends on concentration. Considering only initial rates (that is, no products), the expression for a general rate law is  $\text{rate} = k[\text{A}]^m[\text{B}]^n \dots$ . This reaction is  $m$ th order with respect to A and  $n$ th order with respect to B; the overall reaction order is  $m + n$ .
- › With an accurate method for obtaining initial rates, reaction orders are determined experimentally by varying the concentration of one reactant at a time to see its effect on the rate.
- › By substituting the known rate, concentrations, and reaction orders into the rate law, we solve for the rate constant,  $k$ .

## 16.4 INTEGRATED RATE LAWS: CONCENTRATION CHANGES OVER TIME

The rate laws we've developed so far tell us the rate or concentration at a given instant, allowing us to answer questions such as "How fast is the reaction proceeding at the moment  $y$  moles per liter of A are mixed with  $z$  moles per liter of B?" and "What is [B], when [A] is  $x$  moles per liter?" By employing different forms of the rate laws, called **integrated rate laws**, we can include time as a variable and answer questions such as "How long will it take to use up  $x$  moles per liter of A?" and "What is [A] after  $y$  minutes of reaction?"

### Integrated Rate Laws for First-, Second-, and Zero-Order Reactions

Let's examine the integrated rate laws for reactions that are first, second, or zero order in reactant A:

1. *First-order reactions.* As we've seen, for a general first-order reaction, the rate is the negative of the change in [A] divided by the change in time:

$$\text{Rate} = -\frac{d[\text{A}]}{dt}$$

The rate can also be expressed in terms of the rate law:

$$\text{Rate} = k[\text{A}]$$

Setting these two expressions equal to each other gives

$$-\frac{d[\text{A}]}{dt} = k[\text{A}] \quad \text{or} \quad \frac{1}{[\text{A}]} = d[\text{A}] = -kdt$$

Since the instantaneous rate is the derivative of concentration with respect to time, we find the dependence of [A] on time by integrating this equation from an initial concentration  $[\text{A}]_0$  at  $t = 0$  to any later concentration  $[\text{A}]_t$  at time  $t$ :

$$\int_{[\text{A}]_0}^{[\text{A}]_t} \frac{1}{[\text{A}]} d[\text{A}] = -k \int_0^t dt$$

to obtain

$$\ln[\text{A}]_t - \ln[\text{A}]_0 = -kt$$

The integrated rate law for first-order reactions can also be written as:

$$\ln \frac{[\text{A}]_0}{[\text{A}]_t} = kt \quad (\text{first-order reaction; rate} = k[\text{A}]) \quad (16.4)$$

where  $\ln$  is the natural logarithm,  $[\text{A}]_0$  is the concentration of A at  $t = 0$ , and  $[\text{A}]_t$  is the concentration of A at any time  $t$ .

2. *Second-order reactions with a single reactant, A.* For a general second-order reaction involving only *one* reactant [A], setting the two rate expressions equal to each other gives

$$\text{Rate} = -\frac{d[\text{A}]}{dt} = k[\text{A}]^2 \quad \text{or} \quad \frac{1}{[\text{A}]^2} d[\text{A}] = -kdt$$

Integrating this equation from an initial concentration of  $[\text{A}]_0$  at  $t = 0$  to a final concentration  $[\text{A}]_t$  at time  $t$  gives the integrated rate law for a second-order reaction involving one reactant:

$$\int_{[\text{A}]_0}^{[\text{A}]_t} \frac{1}{[\text{A}]^2} d[\text{A}] = -k \int_0^t dt$$

$$-\frac{1}{[\text{A}]_t} - \left(-\frac{1}{[\text{A}]_0}\right) = -kt$$

which is more conveniently written as:

$$\frac{1}{[A]_t} - \frac{1}{[A]_0} = kt \quad (\text{second-order reaction; rate} = k[A]^2) \quad (16.5)$$

3. *Second-order reactions with two reactants, A and B.* For a general overall second-order reaction which is first-order in *two* reactants A and B, the expression including time is complex. The rate expression for such a reaction is

$$\text{Rate} = -\frac{d[A]}{dt} = -\frac{d[B]}{dt} = k[A][B]$$

Integrating this rate law, assuming  $[A]_0 < [B]_0$  and stoichiometric coefficients of 1 for both reactants, gives the integrated rate law:

$$\frac{1}{[B]_0 - [A]_0} \ln \frac{[A]_0 [B]_t}{[B]_0 [A]_t} = kt$$

We can simplify this relationship by choosing initial concentrations that make the reaction *appear* to be first order. We carry out the reaction with  $[A]$  much greater than  $[B]$  (that is,  $[A]_0 \gg [B]_0$ ); then  $[A]_0$  is so large that relatively little of this reactant is consumed as the reaction proceeds, which means that  $[A]_t \approx [A]_0$ . And, since  $[B]_0$  is much smaller than  $[A]_0$ ,  $[B]_0 - [A]_0 \approx -[A]_0$ . The integrated rate law then simplifies to

$$\frac{1}{-[A]_0} \ln \frac{[A]_0 [B]_t}{[B]_0 [A]_0} = kt \quad \text{or} \quad \ln \frac{[B]_0}{[B]_t} = k[A]_0 t$$

This is the integrated rate law for a first-order reaction in reactant B in which the observed rate constant  $k' = k[A]_0$ :

$$\ln \frac{[B]_0}{[B]_t} = k' t \quad \text{where} \quad k' = k[A]_0$$

The second-order reaction now behaves as a first-order reaction due to a large excess of one reactant, so it is called a **pseudo-first-order** reaction, and the observed rate constant is the pseudo-first-order rate constant that depends on the initial concentration of A.

4. *Zero-order reactions.* For a general zero-order reaction, setting the two rate expressions equal to each other gives

$$\text{Rate} = -\frac{d[A]}{dt} = k[A]^0 = k \quad \text{or} \quad -d[A] = k dt$$

Integrating over time gives the integrated rate law for a zero-order reaction:

$$[A]_t - [A]_0 = -kt \quad (\text{zero-order reaction; rate} = k[A]^0 = k) \quad (16.6)$$

Sample Problem 16.5 shows one way integrated rate laws are applied.

### SAMPLE PROBLEM 16.5

#### Determining the Reactant Concentration After a Given Time

**Problem** At 1000°C, cyclobutane ( $C_4H_8$ ) decomposes in a first-order reaction, with the very high rate constant of  $87 \text{ s}^{-1}$ , to two molecules of ethylene ( $C_2H_4$ ).

- (a) The initial  $C_4H_8$  concentration is 2.00 M. What is the concentration after 0.010 s?  
 (b) How long will it take for 70.0% of the  $C_4H_8$  to decompose?

**Plan** (a) We must find the concentration of cyclobutane at time  $t$ ,  $[C_4H_8]_t$ . We are told that this is a first-order reaction, so we use the integrated first-order rate law:

$$\ln \frac{[C_4H_8]_0}{[C_4H_8]_t} = kt$$

We know  $k$  ( $87 \text{ s}^{-1}$ ),  $t$  (0.010 s), and  $[C_4H_8]_0$  (2.00 M), so we can solve for  $[C_4H_8]_t$ .

#### Student Hot Spot

Student data indicate that you may struggle with applying an integrated rate law. Access the Smartbook to view additional Learning Resources on this topic.

(b) If 70.0% of the  $C_4H_8$  has decomposed, 30.0% of it remains ( $[C_4H_8]_t$ ). We know  $k$  ( $87\text{ s}^{-1}$ ),  $[C_4H_8]_0$  ( $2.00\text{ M}$ ), and  $[C_4H_8]_t$  ( $0.300 \times 2.00\text{ M} = 0.600\text{ M}$ ), so we can solve for  $t$ .

**Solution** (a) Substituting the data into the integrated rate law:

$$\ln \frac{2.00\text{ mol/L}}{[C_4H_8]_t} = (87\text{ s}^{-1})(0.010\text{ s}) = 0.87$$

Taking the antilog of both sides:

$$\frac{2.00\text{ mol/L}}{[C_4H_8]_t} = e^{0.87} = 2.4$$

Solving for  $[C_4H_8]_t$ :

$$[C_4H_8]_t = \frac{2.00\text{ mol/L}}{2.4} = 0.83\text{ mol/L}$$

(b) Substituting the data into the integrated rate law:

$$\ln \frac{2.00\text{ mol/L}}{0.600\text{ mol/L}} = (87\text{ s}^{-1})(t)$$

$$t = 0.014\text{ s}$$

**Check** The concentration remaining after 0.010 s (0.83 mol/L) is less than the starting concentration (2.00 mol/L), which makes sense. Raising  $e$  to an exponent slightly less than 1 should give a number (2.4) slightly less than the value of  $e$  (2.718). Moreover, the final result makes sense: a high rate constant indicates a fast reaction, so it's not surprising that so much decomposes in such a short time.

**Comment** Be sure to note that  $[A]_t$  is the concentration of reactant A that *remains* at time  $t$ , not the amount of A that has reacted.

### FOLLOW-UP PROBLEMS

**16.5A** At  $25^\circ\text{C}$ , hydrogen iodide breaks down very slowly to hydrogen and iodine:  $\text{rate} = k[\text{HI}]^2$ . The rate constant at  $25^\circ\text{C}$  is  $2.4 \times 10^{-21}\text{ L/mol}\cdot\text{s}$ . If 0.0100 mol of  $\text{HI}(\text{g})$  is placed in a 1.0-L container, how long will it take for  $[\text{HI}]$  to reach 0.00900 mol/L (10.0% reacted)?

**16.5B** Hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) decomposes to water and oxygen in a first-order reaction. (a) If 1.28 M  $\text{H}_2\text{O}_2$  changes to 0.85 M in 10.0 min at a given temperature, what is the rate constant for the decomposition reaction? (b) How long will it take for 25% of an initial amount of  $\text{H}_2\text{O}_2$  to decompose? (*Hint*: Assume that  $[\text{H}_2\text{O}_2]_0 = 1.0\text{ M}$ .)

**SOME SIMILAR PROBLEMS** 16.41 and 16.42

## Determining Reaction Orders from an Integrated Rate Law

In Sample Problem 16.3, we found the reaction orders using rate data. If rate data are not available, we rearrange the integrated rate law into an equation for a straight line,  $y = mx + b$ , where  $m$  is the slope and  $b$  is the  $y$ -axis intercept. We then use a graphical method to find the order:

- For a *first-order reaction*, we have

$$\ln \frac{[A]_0}{[A]_t} = kt$$

From Appendix A, we know that  $\ln \frac{a}{b} = \ln a - \ln b$ , so we have

$$\ln [A]_0 - \ln [A]_t = kt$$

Rearranging gives

$$\ln [A]_t = -kt + \ln [A]_0$$

$$y = mx + b$$

Therefore, a plot of  $\ln [A]_t$  vs.  $t$  gives a straight line with slope =  $-k$  and  $y$ -intercept =  $\ln [A]_0$  (Figure 16.10A).

- For a *second-order reaction* with one reactant, we have

$$\frac{1}{[A]_t} - \frac{1}{[A]_0} = kt$$

A First-order reaction

B Second-order reaction

C Zero-order reaction

**Figure 16.10** Graphical method for finding the reaction order from the integrated rate law.

Rearranging gives

$$\frac{1}{[A]_t} = kt + \frac{1}{[A]_0}$$

$$y = mx + b$$

In this case, a plot of  $1/[A]_t$  vs.  $t$  gives a straight line with slope =  $k$  and y-intercept =  $1/[A]_0$  (Figure 16.10B). Note that for a second-order reaction with two reactants, in which one reactant is present in much higher concentration than the other (pseudo-first-order), we obtain results similar to those for a first-order reaction.

- For a *zero-order reaction*, we have

$$[A]_t - [A]_0 = -kt$$

Rearranging gives

$$[A]_t = -kt + [A]_0$$

$$y = mx + b$$

A plot of  $[A]_t$  vs.  $t$  gives a straight line with slope =  $-k$  and y-intercept =  $[A]_0$  (Figure 16.10C).

Some trial-and-error graphical plotting is required to find the reaction order from the concentration and time data:

- If you obtain a straight line when you plot  $\ln$  [reactant] vs.  $t$ , the reaction is *first order* with respect to that reactant.
- If you obtain a straight line when you plot  $1$ /[reactant] vs.  $t$ , the reaction is *second order* with respect to that reactant.
- If you obtain a straight line when you plot [reactant] vs.  $t$ , the reaction is *zero order* with respect to that reactant.

In Figure 16.11 we use this approach to determine the order for the decomposition of  $\text{N}_2\text{O}_5$ . When we plot the data from each column in the table vs. time, we find that the plot of  $\ln [\text{N}_2\text{O}_5]$  vs.  $t$  is linear (part B), while the plots of  $[\text{N}_2\text{O}_5]$  vs.  $t$  (part A) and of  $1/[\text{N}_2\text{O}_5]$  vs.  $t$  (part C) are *not*; therefore, the decomposition is first order in  $\text{N}_2\text{O}_5$ .

**Figure 16.11** Graphical determination of the reaction order for the decomposition of  $\text{N}_2\text{O}_5$ . The time and concentration data in the table are used to obtain the three plots, **A**, **B**, and **C**.

Time (min)	$[\text{N}_2\text{O}_5]$	$\ln [\text{N}_2\text{O}_5]$	$1/[\text{N}_2\text{O}_5]$
0	0.0165	-4.104	60.6
10	0.0124	-4.390	80.6
20	0.0093	-4.68	$1.1 \times 10^2$
30	0.0071	-4.95	$1.4 \times 10^2$
40	0.0053	-5.24	$1.9 \times 10^2$
50	0.0039	-5.55	$2.6 \times 10^2$
60	0.0029	-5.84	$3.4 \times 10^2$

A

B

C

**Figure 16.12** A plot of  $[\text{N}_2\text{O}_5]$  vs. time for three reaction half-lives.

## Reaction Half-Life

The **half-life** ( $t_{1/2}$ ) of a reaction is the time it takes for the reactant concentration to reach *half its initial value*. A half-life has time units appropriate for the specific reaction and is characteristic of that reaction at a given temperature. For example, at  $45^\circ\text{C}$ , the half-life for the decomposition of  $\text{N}_2\text{O}_5$ , which we know is first order, is 24.0 min. Therefore, if we start with, say, 0.0600 mol/L of  $\text{N}_2\text{O}_5$  at  $45^\circ\text{C}$ , 0.0300 mol/L will have reacted after 24 min (one half-life), and 0.0300 mol/L will remain; after 48 min (two half-lives), 0.0150 mol/L will remain; after 72 min (three half-lives), 0.0075 mol/L will remain, and so forth (Figure 16.12). The mathematical expression for the half-life depends on the overall order of the reaction.

**First-Order Reactions** We can derive an expression for the half-life of a first-order reaction from the integrated rate law, which is

$$\ln \frac{[\text{A}]_0}{[\text{A}]_t} = kt$$

By definition, after one half-life,  $t = t_{1/2}$ , and  $[\text{A}]_t = \frac{1}{2}[\text{A}]_0$ . Substituting and canceling  $[\text{A}]_0$  gives

$$\ln \frac{[\text{A}]_0}{\frac{1}{2}[\text{A}]_0} = kt_{1/2} \quad \text{or} \quad \ln 2 = kt_{1/2}$$

Then, solving for  $t_{1/2}$ , we have

$$t_{1/2} = \frac{\ln 2}{k} = \frac{0.693}{k} \quad (\text{first-order process; rate} = k[\text{A}]) \quad (16.7)$$

Notice that  $t_{1/2}$  and  $k$  are *inversely proportional*. Thus, a fast reaction, one with a relatively large rate constant, has a short half-life, and a slow reaction, one with a small rate constant, has a long half-life:

$$k \uparrow, t_{1/2} \downarrow \quad \text{and} \quad k \downarrow, t_{1/2} \uparrow$$

Because no concentration term appears, *for a first-order reaction, the time it takes to reach one-half the starting concentration is a constant and, thus, independent of reactant concentration.*

Decay of an unstable, radioactive nucleus is an example of a first-order process that does not involve a *chemical* change. For example, the half-life for the decay of uranium-235 is  $7.1 \times 10^8$  years. Thus, a sample of ore containing uranium-235 will have half the original mass of uranium-235 after  $7.1 \times 10^8$  years: a sample initially containing 1 kg will contain 0.5 kg of uranium-235, a sample initially containing 1 mg will contain 0.5 mg, and so forth. (We discuss radioactive decay thoroughly in Chapter 24.)

The next two sample problems show some ways to use half-life in calculations: the first is based on molecular scenes.

**SAMPLE PROBLEM 16.6**
**Using Molecular Scenes to Find Quantities at Various Times**

**Problem** Substance A (*green*) decomposes to two other substances, B (*blue*) and C (*yellow*), in a first-order gaseous reaction. The molecular scenes below show a portion of the reaction mixture at two different times:

- (a) Draw a similar molecular scene of the reaction mixture at  $t = 60.0$  s.  
 (b) Find the rate constant for the reaction.  
 (c) If the total pressure ( $P_{\text{total}}$ ) of the mixture is 5.00 atm at 90.0 s, what is the partial pressure of substance B ( $P_{\text{B}}$ )?

**Plan** We are shown molecular scenes of a reaction at two times, with various numbers of reactant and product particles, and have to predict quantities at two later times.

(a) We count the number of A particles and see that A has decreased by half after 30.0 s; thus, the half-life is 30.0 s. The time  $t = 60.0$  s represents two half-lives, so the number of A will decrease by half again, and each A forms one B and one C. (b) We substitute the value of the half-life in Equation 16.7 to find  $k$ . (c) First, we find the numbers of particles at  $t = 90.0$  s, which represents three half-lives. To find  $P_{\text{B}}$ , we multiply the mole fraction of B,  $X_{\text{B}}$ , by  $P_{\text{total}}$  (5.00 atm) (see Equation 5.12). To find  $X_{\text{B}}$ , we know that the number of particles is equivalent to the number of moles, so we divide the number of B particles by the total number of particles.

**Solution** (a) The number of A particles decreased from 8 to 4 in one half-life (30.0 s), so after two half-lives (60.0 s), the number of A particles will be 2 (1/2 of 4). Each A decomposes to 1 B and 1 C, so 6 (8 - 2) particles of A form 6 of B and 6 of C (see margin).

(b) Finding the rate constant,  $k$ :

$$t_{1/2} = \frac{0.693}{k} \quad \text{so} \quad k = \frac{0.693}{t_{1/2}} = \frac{0.693}{30.0 \text{ s}} = 2.31 \times 10^{-2} \text{ s}^{-1}$$

(c) Finding the number of particles after 90.0 s: After a third half-life, there will be 1 A, 7 B, and 7 C particles.

Finding the mole fraction of B,  $X_{\text{B}}$ :

$$X_{\text{B}} = \frac{7 \text{ B particles}}{1 + 7 + 7 \text{ total particles}} = \frac{7}{15} = 0.467$$

Finding the partial pressure of B,  $P_{\text{B}}$ :

$$P_{\text{B}} = X_{\text{B}} \times P_{\text{total}} = 0.467 \times 5.00 \text{ atm} = 2.33 \text{ atm}$$

**Check** For (b), rounding gives 0.7/30, which is a bit over 0.02, so the answer seems correct. For (c),  $X_{\text{B}}$  is almost 0.5, so  $P_{\text{B}}$  is a bit less than half of 5 atm, or <2.5 atm.

**FOLLOW-UP PROBLEMS**

**16.6A** Substance X (*black*) changes to substance Y (*red*) in a first-order gaseous reaction. The scenes below represent the reaction mixture in a cubic container at two different times:

- (a) Draw a scene that represents the mixture at 5.0 min.  
 (b) If each particle in the container actually represents 0.20 mol of particles and the volume of the cubic container is 0.50 L, what is the molarity of X at 10.0 min?

**16.6B** Substance A (*red*) changes to substance B (*blue*) in a first-order gaseous reaction. The scenes below represent the reaction mixture at three different times:

- (a) What is the time at which the third scene occurs?  
 (b) If each particle in the circle actually represents 0.10 mol of particles and the volume of the container is 0.25 L, what is the molarity of A at 72 min?

**SOME SIMILAR PROBLEMS** 16.43 and 16.44

### SAMPLE PROBLEM 16.7

### Determining the Half-Life of a First-Order Reaction

**Problem** Cyclopropane is the smallest cyclic hydrocarbon. Because its  $60^\circ$  bond angles reduce orbital overlap, its bonds are weak. As a result, it is thermally unstable and rearranges to propene at  $1000^\circ\text{C}$  via the following first-order reaction:

The rate constant is  $9.2 \text{ s}^{-1}$ .

- (a) What is the half-life of the reaction?  
 (b) How long does it take for the concentration of cyclopropane to reach one-quarter of the initial value?

**Plan** (a) The cyclopropane rearrangement is first order, so to find  $t_{1/2}$  we use Equation 16.7 and substitute for  $k$  ( $9.2 \text{ s}^{-1}$ ). (b) Each half-life decreases the concentration to one-half of its initial value, so two half-lives decrease it to one-quarter of its initial value.

**Solution** (a) Solving for  $t_{1/2}$ :

$$\begin{aligned} t_{1/2} &= \frac{\ln 2}{k} = \frac{0.693}{9.2 \text{ s}^{-1}} \\ &= 0.075 \text{ s} \end{aligned}$$

It takes 0.075 s for half the cyclopropane to form propene at this temperature.

- (b) Finding the time to reach one-quarter of the initial concentration:

$$\begin{aligned} \text{Time} &= 2(t_{1/2}) = 2(0.075 \text{ s}) \\ &= 0.15 \text{ s} \end{aligned}$$

**Check** For part (a), rounding gives  $0.7/9 \text{ s}^{-1} = 0.08 \text{ s}$ , so the answer seems correct.

### FOLLOW-UP PROBLEMS

**16.7A** Iodine-123 is used to study thyroid gland function. This radioactive isotope breaks down in a first-order process with a half-life of 13.1 h. What is the rate constant for the process?

**16.7B** The half-life of a pesticide determines its persistence in the environment. A common pesticide degrades in a first-order process with a rate constant of  $9 \times 10^{-2} \text{ day}^{-1}$ .

- (a) What is the half-life of the breakdown reaction?  
 (b) What fraction of the pesticide remains in the environment after 40 days?

**SOME SIMILAR PROBLEMS** 16.45 and 16.46

**Second-Order Reactions** In contrast to the half-life of a first-order reaction, the half-life of a simple second-order reaction *does* depend on reactant concentration:

$$t_{1/2} = \frac{1}{k[A]_0} \quad (\text{second-order process; rate} = k[A]^2)$$

Note that here *the half-life is inversely proportional to the initial reactant concentration*. This relationship means that a second-order reaction with a high initial reactant concentration has a *shorter* half-life, and one with a low initial reactant concentration has a *longer* half-life. It also means that, for a particular reaction, each successive half-life is double the preceding one, since  $[A]$  is halved during each half-life. (Note, however, that since a second-order reaction with two reactants, in which one reactant is present in much higher concentration than the other, follows first-order kinetics, its half-life behaves like the half-life of a first-order reaction.)

**Zero-Order Reactions** In contrast to the half-life of a second-order reaction, *the half-life of a zero-order reaction is directly proportional to the initial reactant concentration*:

$$t_{1/2} = \frac{[A]_0}{2k} \quad (\text{zero-order process; rate} = k)$$

Thus, if a zero-order reaction begins with a high reactant concentration, it has a longer half-life than if it begins with a low reactant concentration.

Table 16.4 summarizes the features of zero-, first-, and second-order reactions.

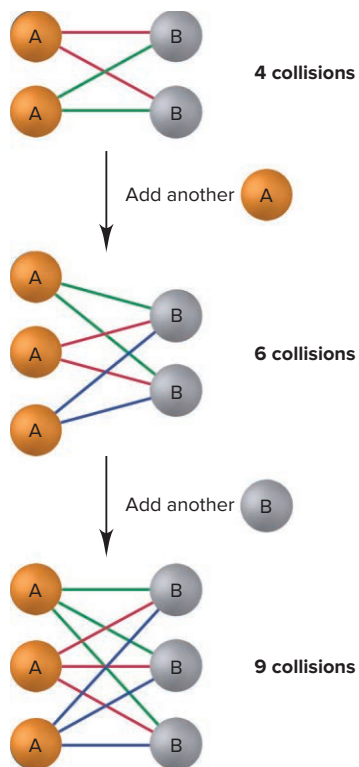

Table 16.4

An Overview of Zero-Order, First-Order, and Simple Second-Order Reactions

	Zero Order	First Order	Second Order
Rate law	rate = $k$	rate = $k[A]$	rate = $k[A]^2$
Units for $k$	mol/L·s	1/s	L/mol·s
Half-life	$\frac{[A]_0}{2k}$	$\frac{\ln 2}{k}$	$\frac{1}{k[A]_0}$
Integrated rate law in straight-line form	$[A]_t = -kt + [A]_0$	$\ln [A]_t = -kt + \ln [A]_0$	$1/[A]_t = kt + 1/[A]_0$
Plot for straight line	$[A]_t$ vs. $t$	$\ln [A]_t$ vs. $t$	$1/[A]_t$ vs. $t$
Slope, y-intercept	$-k$ , $[A]_0$	$-k$ , $\ln [A]_0$	$k$ , $1/[A]_0$
			

## › Summary of Section 16.4

- › Integrated rate laws are used to find either the time needed to reach a certain concentration of reactant or the concentration present after a given time.
- › Rearrangements of the integrated rate laws that give equations that graph as a straight line allow us to determine reaction orders and rate constants graphically.
- › The half-life is the time needed for the reactant concentration to reach half its initial value; for first-order reactions, the half-life is constant, that is, independent of concentration.

**Figure 16.13** The number of possible collisions is the product, not the sum, of reactant concentrations.

## 16.5 THEORIES OF CHEMICAL KINETICS

As was pointed out in Section 16.1, concentration and temperature have major effects on reaction rate. Chemists employ two models—*collision theory* and *transition state theory*—to explain these effects.

### Collision Theory: Basis of the Rate Law

The basic tenet of **collision theory** is that particles—atoms, molecules, or ions—must collide to react. But number of collisions can't be the only factor determining rate, or all reactions would be over in an instant. For example, at 1 atm and 20°C, the N<sub>2</sub> and O<sub>2</sub> molecules in 1 mL of air experience about 10<sup>27</sup> collisions per second. If all that was needed for a reaction to occur was an N<sub>2</sub> molecule colliding with an O<sub>2</sub> molecule, our atmosphere would consist of almost all NO; in fact, only traces are present. Thus, this theory also relies on the concepts of collision energy and molecular structure to explain the effects of concentration and temperature on rate.

**Why Concentrations Are Multiplied in the Rate Law** Particles must collide to react, so the collision frequency, the number of collisions per unit time, provides an *upper limit* on how fast a reaction can take place. In its basic form, collision theory deals with one-step reactions, those in which two particles collide and form products:  $A + B \rightarrow$  products. Suppose we have only two particles of A and two of B confined in a vessel. Figure 16.13 shows that four A-B collisions are possible. The laws of probability tell us that the number of collisions depends on the *product* of the numbers of reactant particles, not their sum. Thus, when we add another particle of A, six A-B collisions (3 × 2) are possible, not just five (3 + 2). Similarly, when we add another particle of B, nine A-B collisions (3 × 3) are possible, not just six (3 + 3). Thus, collision theory explains why we *multiply* the concentrations in the rate law to obtain the observed rate.

**The Effect of Temperature on the Rate Constant and the Rate** Temperature typically has a dramatic effect on reaction rate: for many reactions near room temperature, an increase of 10 K (10°C) doubles or triples the rate. Figure 16.14A shows kinetic data for an organic reaction—hydrolysis, or reaction with water, of the organic compound ethyl acetate. To understand the effect of temperature, we measure concentrations and times for the reaction run at different temperatures. Solving each rate expression for  $k$  and plotting the results (Figure 16.14B), we find that  $k$  *increases exponentially as  $T$  increases*.

**Figure 16.14** Increase of the rate constant with temperature for the hydrolysis of an ester.

**A**

Expt	[Ester]	[H <sub>2</sub> O]	$T$ (K)	Rate (mol/L·s)	$k$ (L/mol·s)
1	0.100	0.200	288	$1.04 \times 10^{-3}$	0.0521
2	0.100	0.200	298	$2.02 \times 10^{-3}$	0.101
3	0.100	0.200	308	$3.68 \times 10^{-3}$	0.184
4	0.100	0.200	318	$6.64 \times 10^{-3}$	0.332

These results are consistent with findings obtained in 1889 by the Swedish chemist Svante Arrhenius. In its modern form, the **Arrhenius equation** is

$$k = Ae^{-E_a/RT} \quad (16.8)$$

where  $k$  is the rate constant,  $e$  is the base of natural logarithms,  $T$  is the absolute temperature, and  $R$  is the universal gas constant. (We'll focus on the term  $E_a$  in the next subsection and on the term  $A$  a bit later.) Note the relationship between  $k$  and  $T$ , especially that  $T$  is in the denominator of a negative exponent. Thus, *as  $T$  increases, the value of the negative exponent becomes smaller, which means  $k$  becomes larger, so the rate increases*:

$$\text{Higher } T \Rightarrow \text{larger } k \Rightarrow \text{increased rate}$$

**The Central Importance of Activation Energy** The effect of temperature on  $k$  is closely related to the **activation energy** ( $E_a$ ) of a reaction, an energy *threshold* that the colliding molecules must exceed in order to react. As an analogy, in order to succeed

at the high jump, an athlete must exert at least enough energy to get over the bar. Similarly, if reactant molecules collide with a certain minimum energy, they reach an *activated state*, from which they can change to products (Figure 16.15); collisions that occur with an energy below this minimum leave the reactants unchanged.

As you can see from Figure 16.15, a reversible reaction has two activation energies. The activation energy for the forward reaction,  $E_{a(\text{fwd})}$ , is the energy difference between the activated state and the reactants; the activation energy for the reverse reaction,  $E_{a(\text{rev})}$ , is the energy difference between the activated state and the products. The reaction represented in the diagram is exothermic ( $\Delta H_{\text{rxn}} < 0$ ) in the forward direction. Thus, the products are at a lower energy than the reactants, and  $E_{a(\text{fwd})}$  is less than  $E_{a(\text{rev})}$ . This difference equals the enthalpy of reaction,  $\Delta H_{\text{rxn}}$ :

$$\Delta H_{\text{rxn}} = E_{a(\text{fwd})} - E_{a(\text{rev})} \quad (16.9)$$

**The Effect of Temperature on Collision Energy** As was mentioned in Section 16.1, a rise in temperature has two effects on moving particles: it causes a higher collision frequency and a higher collision energy. Let's see how each affects rate.

- *Collision frequency.* If particles move faster, they collide more often. Calculations show that a 10 K rise in temperature from, say, 288 K to 298 K, increases the average molecular speed by 2%, which would lead to, at most, a 4% increase in rate. Thus, higher collision frequency cannot possibly account for the doubling or tripling of rates observed with a 10 K rise. Indeed, the effect of temperature on collision frequency is only a minor factor.
- *Collision energy.* On the other hand, the effect of temperature on collision energy is a major factor. At a given temperature, the fraction  $f$  of collisions with energy equal to or greater than  $E_a$  is

$$f = e^{-E_a/RT}$$

where  $e$  is the base of natural logarithms,  $T$  is the absolute temperature, and  $R$  is the universal gas constant. The right side of this expression appears in the Arrhenius equation (Equation 16.8), which shows that a rise in  $T$  causes a larger  $k$ . We now see why—a rise in temperature increases the kinetic energy of the reactant particles and enlarges the fraction of collisions with enough energy to exceed  $E_a$  (Figure 16.16). It is important to note that increasing the temperature does not change the value of  $E_a$ —only the fraction of collisions with enough energy to get over this energy barrier.

Table 16.5 (next page) shows that the magnitudes of both  $E_a$  and  $T$  affect the size of this fraction for the hydrolysis of ethyl acetate that we discussed above:

- In the top portion of the table, temperature is held constant, and the fraction of sufficiently energetic collisions shrinks several orders of magnitude with each 25-kJ/mol increase in  $E_a$ . (To extend the high jump analogy, as the height of the bar is raised, a smaller fraction of the athletes have enough energy to jump over it.)
- In the bottom portion,  $E_a$  is held constant, and the fraction nearly doubles for each 10 K (10°C) rise in temperature.

**Figure 16.15** Energy-level diagram for a reaction. Like a high jumper with enough energy to go over the bar, molecules must collide with enough energy,  $E_a$ , to reach an activated state. (This reaction is reversible and is exothermic in the forward direction.) Source: © Sipa via AP Images

**Figure 16.16** The effect of temperature on the distribution of collision energies.

**The Effect of  $E_a$  and  $T$  on the Fraction ( $f$ ) of Collisions with Sufficient Energy to Allow Reaction**

Table 16.5

$E_a$ (kJ/mol)	$f$ (at $T = 298$ K)
50	$1.70 \times 10^{-9}$
75	$7.03 \times 10^{-14}$
100	$2.90 \times 10^{-18}$
$T$	$f$ (at $E_a = 50$ kJ/mol)
25°C (298 K)	$1.70 \times 10^{-9}$
35°C (308 K)	$3.29 \times 10^{-9}$
45°C (318 K)	$6.12 \times 10^{-9}$

**Figure 16.17** Graphical determination of the activation energy.

Therefore, *the smaller the activation energy (or the higher the temperature), the larger the fraction of sufficiently energetic collisions, the larger the value of  $k$ , and the higher the reaction rate:*

$$\text{Smaller } E_a \text{ (or higher } T) \implies \text{larger } f \implies \text{larger } k \implies \text{higher rate}$$

**Calculating the Activation Energy** We can calculate  $E_a$  from the Arrhenius equation by taking the natural logarithm of both sides of the equation, which recasts it into the form of an equation for a straight line:

$$k = Ae^{-E_a/RT}$$

$$\ln k = \ln A - \frac{E_a}{R} \left( \frac{1}{T} \right)$$

$$y = b + mx$$

A plot of  $\ln k$  vs.  $1/T$  gives a straight line whose slope is  $-E_a/R$  and whose y-intercept is  $\ln A$  (Figure 16.17). We know the constant  $R$ , so we can determine  $E_a$  graphically from a series of  $k$  values at different temperatures.

We can find  $E_a$  in another way if we know the rate constants at two temperatures,  $T_2$  and  $T_1$ :

$$\ln k_2 = \ln A - \frac{E_a}{R} \left( \frac{1}{T_2} \right) \quad \ln k_1 = \ln A - \frac{E_a}{R} \left( \frac{1}{T_1} \right)$$

When we subtract  $\ln k_1$  from  $\ln k_2$ , the term  $\ln A$  drops out and the other terms can be rearranged to give

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \quad (16.10)$$

Then, we can solve for  $E_a$ , as in the next sample problem.

### SAMPLE PROBLEM 16.8

### Determining the Energy of Activation

**Problem** The decomposition of hydrogen iodide  $2\text{HI}(g) \longrightarrow \text{H}_2(g) + \text{I}_2(g)$ , has rate constants of  $9.51 \times 10^{-9}$  L/mol·s at 500. K and  $1.10 \times 10^{-5}$  L/mol·s at 600. K. Find  $E_a$ .

**Plan** We are given the rate constants,  $k_1$  and  $k_2$ , at two temperatures,  $T_1$  and  $T_2$ , so we substitute into Equation 16.10 and solve for  $E_a$ .

**Solution** Rearranging Equation 16.10 to solve for  $E_a$ :

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$$

$$E_a = R \left( \ln \frac{k_2}{k_1} \right) \left( \frac{1}{T_1} - \frac{1}{T_2} \right)^{-1}$$

$$= (8.314 \text{ J/mol}\cdot\text{K}) \left( \ln \frac{1.10 \times 10^{-5} \text{ L/mol}\cdot\text{s}}{9.51 \times 10^{-9} \text{ L/mol}\cdot\text{s}} \right) \left( \frac{1}{500. \text{ K}} - \frac{1}{600. \text{ K}} \right)^{-1}$$

$$= 1.76 \times 10^5 \text{ J/mol} = 1.76 \times 10^2 \text{ kJ/mol}$$

**Comment** Be sure to retain the same number of significant figures in  $1/T$  as you have in  $T$ , or a significant error could be introduced. Round to the correct number of significant figures only at the final answer. On most pocket calculators, the expression  $(1/T_1 - 1/T_2)$  is entered as follows:  $(T_1)(1/x) - (T_2)(1/x) =$

### FOLLOW-UP PROBLEMS

**16.8A** The reaction  $2\text{NOCl}(g) \longrightarrow 2\text{NO}(g) + \text{Cl}_2(g)$  has an  $E_a$  of  $1.00 \times 10^2$  kJ/mol and a rate constant of 0.286 L/mol·s at 500. K. What is the rate constant at 490. K?

**16.8B** The decomposition reaction  $2\text{NO}_2(g) \longrightarrow 2\text{NO}(g) + \text{O}_2(g)$  has an  $E_a$  of  $1.14 \times 10^5$  J/mol and a rate constant of  $7.02 \times 10^{-3}$  L/mol·s at 500. K. At what temperature will the rate be twice as fast?

**SOME SIMILAR PROBLEMS** 16.61, 16.62, and 16.65

**The Effect of Molecular Structure on Rate** At ordinary temperatures, the enormous number of collisions per second between reactant particles is reduced by six or more orders of magnitude by counting only those with enough energy to react. And, even this tiny fraction of all collisions is typically much larger than the number of **effective collisions**, those that actually lead to product because *the atoms that become bonded in the product make contact*. Thus, to be effective, a collision must have enough energy *and* the appropriate *molecular orientation*.

In the Arrhenius equation, molecular orientation is contained in the term  $A$ :

$$k = Ae^{-E_a/RT}$$

This term is the **frequency factor**, the product of the collision frequency  $Z$  and an **orientation probability factor**,  $p$ , which is specific for each reaction:

$$A = pZ$$

The factor  $p$  is related to the structural complexity of the reactants. You can think of  $p$  as the ratio of effectively oriented collisions to all possible collisions. Figure 16.18 shows a few of the possible collision orientations for the following reaction:

Of the five orientations shown, only one has the effective orientation, with the N of NO making contact with an O of NO<sub>3</sub> to form a new nitrogen-oxygen bond. Actually, the  $p$  value for this reaction is 0.006: only 6 collisions in every 1000 (1 in 167) have the correct orientation.

*The more complex the molecular structure, the smaller the  $p$  value is.* Individual atoms are spherical, so reactions between them have  $p$  values near 1: as long as reacting atoms collide with enough energy, the product can form. At the other extreme are biochemical reactions in which two small molecules (or portions of larger molecules) react only when they collide with enough energy on a specific tiny region of a giant protein. The  $p$  value for these reactions is often much less than  $10^{-6}$ , fewer than one in a million. The fact that countless such biochemical reactions are occurring in you right now attests to the astounding number of collisions per second!

## Transition State Theory: What the Activation Energy Is Used For

Collision theory explains the importance of effective collisions, and **transition state theory** focuses on the high-energy species that exists at the moment of an effective collision when reactants are becoming products.

**Visualizing the Transition State** As two molecules approach each other, repulsions between their electron clouds continually increase, so they slow down as some of their kinetic energy is converted to potential energy. If they collide, but the energy of the collision is *less* than the activation energy, the molecules bounce off each other and no reaction occurs.

However, in a tiny fraction of collisions in which the molecules are moving fast enough, *their kinetic energies push them together with enough force to overcome the repulsions and surpass the activation energy*. And, in an even tinier fraction of these sufficiently energetic collisions, the molecules are oriented effectively. In those cases, nuclei in one molecule attract electrons in the other, atomic orbitals overlap, electron densities shift, and some bonds lengthen and weaken while others shorten and strengthen. At some point during this smooth transformation, *a species with partial bonds exists* that is neither reactant nor product. This very unstable species, called the **transition state** (or **activated complex**) exists only at the instant of highest potential energy. Thus, *the activation energy of a reaction is used to reach the transition state*.

Transition states cannot be isolated, but the work of Ahmed H. Zewail, who received the 1999 Nobel Prize in chemistry, greatly expanded our knowledge of them. Using lasers pulsing at the time scale of bond vibrations ( $10^{-15}$  s), his team observed transition states forming and decomposing. A few, such as the one that forms as methyl bromide reacts with hydroxide ion, have been well studied:

**Figure 16.18** The importance of molecular orientation to an effective collision. In the one effective orientation (bottom), contact occurs between the atoms that become bonded in the product.

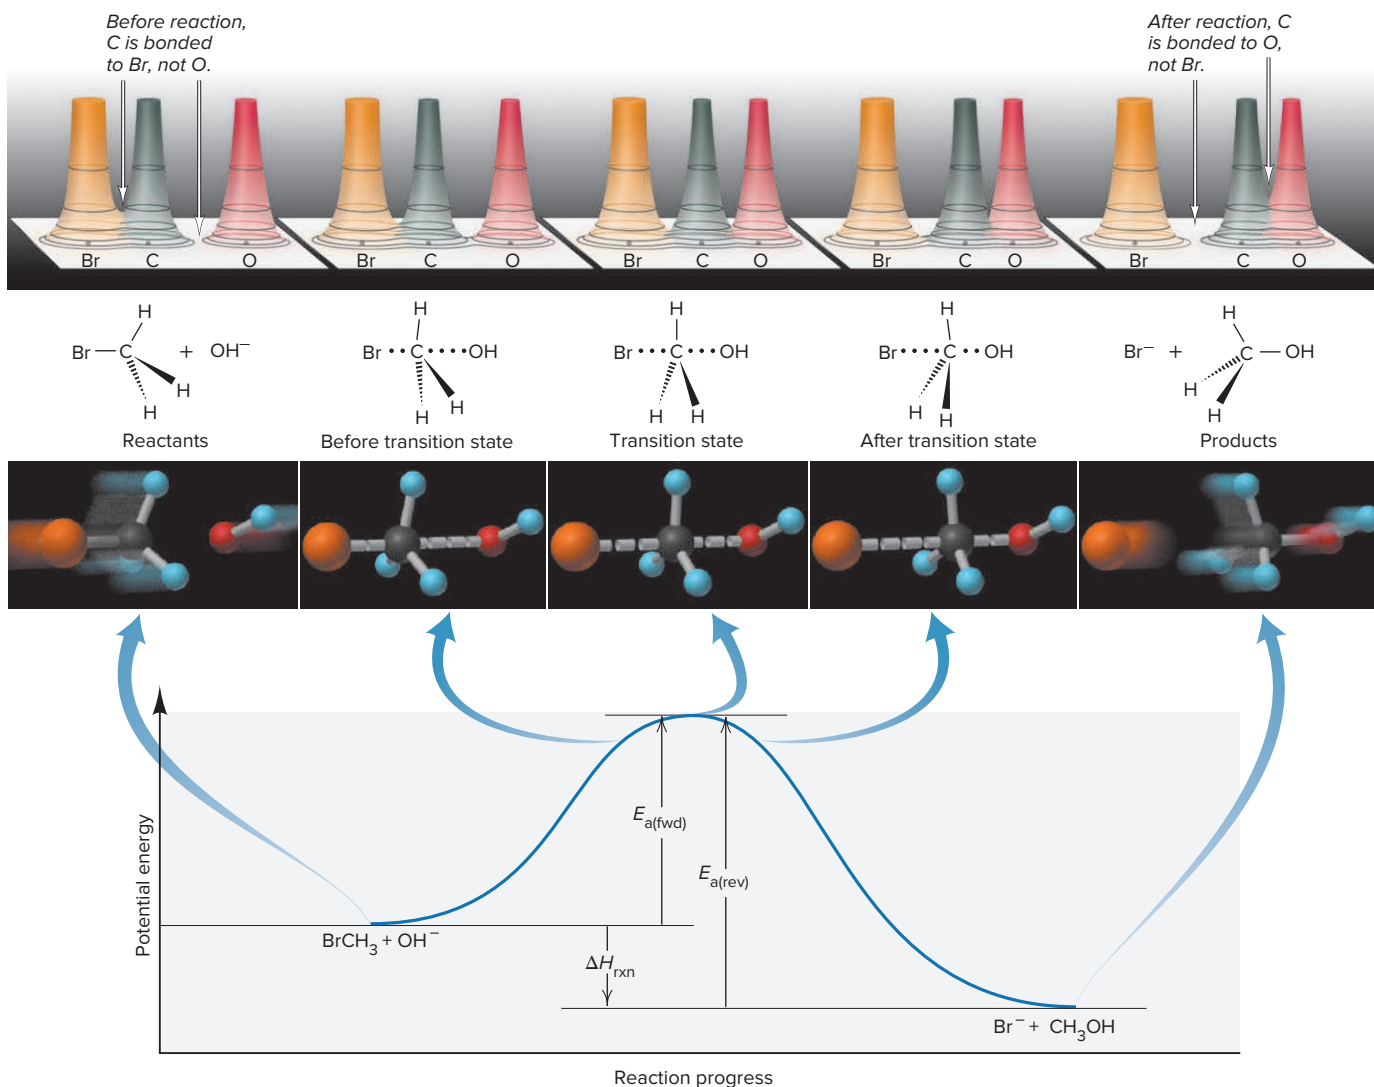

**Figure 16.19** The transition state of the reaction between  $\text{BrCH}_3$  and  $\text{OH}^-$ . Note the partial (dashed)  $\text{Br}-\text{C}$  and  $\text{C}-\text{O}$  bonds and the trigonal bipyramidal shape.

The electronegative bromine makes the carbon in  $\text{BrCH}_3$  partially positive, and the carbon attracts the negatively charged oxygen in  $\text{OH}^-$ . As a  $\text{C}-\text{O}$  bond begins to form, the  $\text{Br}-\text{C}$  bond begins to weaken. In the transition state (Figure 16.19), C is surrounded by five atoms (trigonal bipyramidal; Section 10.2), which never occurs in carbon's stable compounds. This high-energy species has three normal  $\text{C}-\text{H}$  bonds and two partial bonds, one from C to O and the other from Br to C.

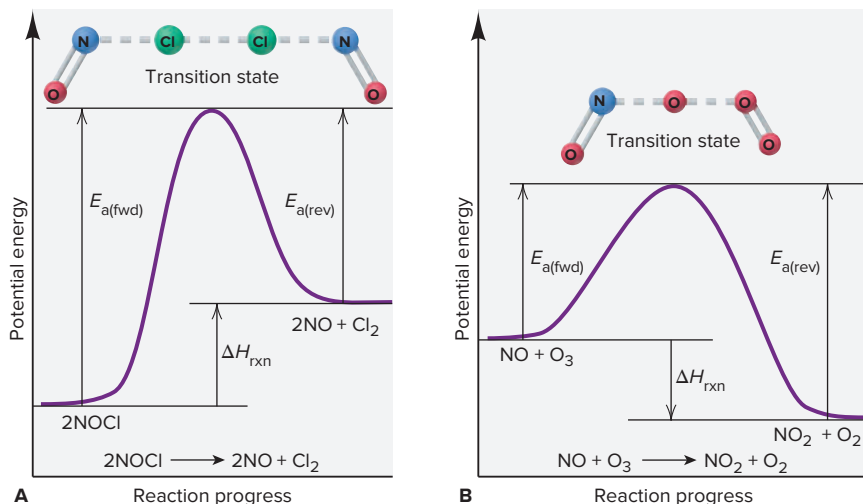

Reaching the transition state does not guarantee that a reaction will proceed to products because *a transition state can change in either direction*. In this case, if the  $\text{C}-\text{O}$  bond continues to strengthen, products form; but, if the  $\text{Br}-\text{C}$  bond becomes stronger again, the transition state reverts to reactants.

**Depicting the Change with a Reaction Energy Diagram** A useful way to depict these events is with a **reaction energy diagram**, which plots how potential energy changes as the reaction proceeds from reactants to products (the *reaction progress*). The diagram shows the relative energy levels of reactants, products, and transition state, as well as the forward and reverse activation energies and the enthalpy of reaction.

The bottom of Figure 16.20 shows the diagram for the reaction of  $\text{BrCH}_3$  and  $\text{OH}^-$ . This reaction is exothermic, so reactants are higher in energy than products, which means  $E_{a(\text{fwd})}$  is less than  $E_{a(\text{rev})}$ . Above the diagram are molecular-scale views at various points during the reaction and corresponding structural formulas. At the top of the figure

**Figure 16.20** Depicting the reaction between  $\text{BrCH}_3$  and  $\text{OH}^-$ . In order (bottom to top) are the reaction energy diagram with blow-up arrows at five points during the reaction, molecular-scale views, structural formulas, and electron density relief maps. Note the gradual, simultaneous  $\text{C}-\text{O}$  bond forming and  $\text{Br}-\text{C}$  bond breaking.

**Figure 16.21** Reaction energy diagrams and possible transition states for two reactions.

are electron density relief maps of the Br, C, and O atoms: note the gradual change in electron density from C overlapping Br (*left*) to C overlapping O (*right*).

Transition state theory proposes that *every reaction (or every step in an overall reaction) goes through its own transition state*. Figure 16.21 presents reaction energy diagrams for two gas-phase reactions. The reaction shown in Figure 16.21A is endothermic, while the reaction shown in Figure 16.21B is exothermic. In each case, the structure of the transition state is predicted from the orientations of the reactant atoms that must become bonded in the product.

### SAMPLE PROBLEM 16.9

### Drawing Reaction Energy Diagrams and Transition States

**Problem** A key reaction in the upper atmosphere is

The  $E_{\text{a}(\text{fwd})}$  is 19 kJ, and the  $\Delta H_{\text{rxn}}$  for the reaction as written is  $-392$  kJ. Draw a reaction energy diagram, predict a structure for the transition state, and calculate  $E_{\text{a}(\text{rev})}$ .

**Plan** The reaction is highly exothermic ( $\Delta H_{\text{rxn}} = -392$  kJ), so the products are much lower in energy than the reactants. The small  $E_{\text{a}(\text{fwd})}$  (19 kJ) means that the energy of the reactants lies slightly below that of the transition state. We use Equation 16.9 to calculate  $E_{\text{a}(\text{rev})}$ . To predict the transition state, we sketch the species and note that one of the bonds in  $\text{O}_3$  weakens, and this partially bonded O begins forming a bond to the separate O atom.

**Solution** Solving for  $E_{\text{a}(\text{rev})}$ :

$$\Delta H_{\text{rxn}} = E_{\text{a}(\text{fwd})} - E_{\text{a}(\text{rev})}$$

$$\text{So, } E_{\text{a}(\text{rev})} = E_{\text{a}(\text{fwd})} - \Delta H_{\text{rxn}} = 19 \text{ kJ} - (-392 \text{ kJ}) = 411 \text{ kJ}$$

The reaction energy diagram (not drawn to scale), with transition state, is shown in the margin.

**Check** Rounding to find  $E_{\text{a}(\text{rev})}$  gives  $\sim 20 + 390 = 410$ .

### FOLLOW-UP PROBLEMS

**16.9A** The following reaction energy diagram depicts another key atmospheric reaction. Label the axes, identify  $E_{\text{a}(\text{fwd})}$ ,  $E_{\text{a}(\text{rev})}$ , and  $\Delta H_{\text{rxn}}$ , draw and label the transition state, and calculate  $E_{\text{a}(\text{rev})}$  for the reaction.

**16.9B** For the gas phase reaction  $\text{Cl}(g) + \text{HBr}(g) \longrightarrow \text{HCl}(g) + \text{Br}(g)$ ,  $E_{\text{a}(\text{fwd})} = 7 \text{ kJ}$  and  $E_{\text{a}(\text{rev})} = 72 \text{ kJ}$ . Draw a reaction energy diagram; include a predicted structure for the transition state and the value of  $\Delta H_{\text{rxn}}$ .

**SOME SIMILAR PROBLEMS** 16.63, 16.64, and 16.66

### › Summary of Section 16.5

- › According to collision theory, reactant particles must collide to react, and the number of possible collisions is found by multiplying the numbers of reactant particles.
- › As the Arrhenius equation shows, a rise in temperature increases the rate because it increases the rate constant.
- › The activation energy,  $E_{\text{a}}$ , is the minimum energy needed for colliding particles to react.
- › The relative  $E_{\text{a}}$  values for the forward and reverse reactions depend on whether the overall reaction is exothermic or endothermic.
- › At higher temperatures, more collisions have enough energy to exceed  $E_{\text{a}}$ .
- ›  $E_{\text{a}}$  can be determined graphically from  $k$  values obtained at different  $T$  values.
- › Molecules must collide with an effective orientation for them to react, so structural complexity decreases rate.
- › Transition state theory focuses on the change of kinetic energy to potential energy as reactant particles collide and form an unstable transition state.
- › Given a sufficiently energetic collision and an effective molecular orientation, the reactant species form the transition state, which either continues toward product(s) or reverts to reactant(s).
- › A reaction energy diagram depicts the changing potential energy throughout a reaction's progress from reactants through transition states to products.

## 16.6 REACTION MECHANISMS: THE STEPS FROM REACTANT TO PRODUCT

You can't understand how a car works by examining the body, wheels, and dashboard, or even the engine as a whole. You need to look inside the engine to see how its parts fit together and function. Similarly, by examining the overall balanced equation, we can't know how a reaction "works." We must look "inside the reaction" to see how reactants change into products, step by step.

The steps for most reactions can be described by a **reaction mechanism**, a sequence of single reaction steps that sum to the overall equation. For example, a possible mechanism for the overall reaction

might involve these three simpler steps:

Adding the steps and canceling common substances gives the overall equation:

A mechanism is a hypothesis about how a reaction occurs; chemists *propose* a mechanism and then *test* to see that it fits with the observed rate law.

### Elementary Reactions and Molecularity

The individual steps that make up a reaction mechanism are called **elementary reactions** (or **elementary steps**). Each describes a *single molecular event*—one particle decomposing, two particles combining, and so forth.

An elementary step is characterized by its **molecularity**, the number of *reactant* particles in the step. Consider the mechanism for the breakdown of ozone in the stratosphere. The overall equation is

A two-step mechanism has been proposed:

- The first step is a **unimolecular reaction**, one that involves the decomposition or rearrangement of a single particle ( $\text{O}_3$ ).
- The second step is a **bimolecular reaction**, one in which two particles ( $\text{O}_3$  and  $\text{O}$ ) collide and react.

Some *termolecular* elementary steps occur, but they are extremely rare because the probability of three particles colliding simultaneously with enough energy and an effective orientation is very small. Higher molecularities are not known. Therefore, in general, *we propose unimolecular and/or bimolecular reactions as reasonable steps in a mechanism.*

Because an elementary reaction occurs in one step, its rate law, unlike that for an overall reaction, *can* be deduced from the reaction stoichiometry: *reaction order equals molecularity.* Therefore, *only* for an elementary step, *we use the equation coefficients as the reaction orders in the rate law* (Table 16.6). For example, in step 2 of the proposed mechanism for the decomposition of  $\text{O}_3$ , one  $\text{O}_3$  molecule collides with one  $\text{O}$  atom; therefore, this step is first-order in  $\text{O}_3$  and first-order in  $\text{O}$  and the rate law for this step is  $\text{rate} = k[\text{O}_3][\text{O}]$ .

Table 16.6

Rate Laws for General Elementary Steps

Elementary Step	Molecularity	Rate Law
$\text{A} \longrightarrow \text{product}$	Unimolecular	$\text{Rate} = k[\text{A}]$
$2\text{A} \longrightarrow \text{product}$	Bimolecular	$\text{Rate} = k[\text{A}]^2$
$\text{A} + \text{B} \longrightarrow \text{product}$	Bimolecular	$\text{Rate} = k[\text{A}][\text{B}]$
$2\text{A} + \text{B} \longrightarrow \text{product}$	Termolecular	$\text{Rate} = k[\text{A}]^2[\text{B}]$

## SAMPLE PROBLEM 16.10

## Determining Molecularities and Rate Laws for Elementary Steps

**Problem** The following elementary steps are proposed for a reaction mechanism:

- (a) Write the balanced equation for the overall reaction.  
 (b) Determine the molecularity of each step.  
 (c) Write the rate law for each step.

**Plan** We find the overall equation by adding the elementary steps. The molecularity of each step equals the total number of *reactant* particles. We write the rate law for each step using the equation coefficients as reaction orders.

**Solution** (a) Writing the overall balanced equation:

(b) Determining the molecularity of each step: The first step has one reactant,  $\text{Cl}_2$ , so it is **unimolecular**. The second and third steps each have two reactants ( $\text{Cl}$  and  $\text{CHCl}_3$ ;  $\text{Cl}$  and  $\text{CCl}_3$ ), so they are **bimolecular**.

(c) Writing the rate laws for the elementary steps:

**Check** In part (a), be sure the equation is balanced; in part (c), be sure the substances in brackets are the *reactants* of each elementary step.

### FOLLOW-UP PROBLEMS

**16.10A** The mechanism below is proposed for the decomposition of hydrogen peroxide:

(a) Write the balanced equation for the overall reaction. (b) Determine the molecularity of each step. (c) Write the rate law for each step.

**16.10B** The following elementary steps are proposed for a reaction mechanism:

(a) Write the balanced equation for the overall reaction. (b) Determine the molecularity of each step. (c) Write the rate law for each step.

**SOME SIMILAR PROBLEMS** 16.74(a), 16.74(c), 16.75(a), and 16.75(c)

## The Rate-Determining Step of a Reaction Mechanism

All the elementary steps in a mechanism have their own rates. However, one step is usually *much* slower than the others. This step, called the **rate-determining step** (or **rate-limiting step**), limits how fast the overall reaction proceeds. Therefore, *the rate law of the rate-determining step becomes the rate law for the overall reaction.* ▶

Consider the reaction between nitrogen dioxide and carbon monoxide:

If this reaction were an elementary step—that is, if the mechanism consisted of only one step—we could immediately write the overall rate law as

$$\text{Rate} = k[\text{NO}_2][\text{CO}]$$

But, as you saw in Sample Problem 16.3, experimental data show the rate law is

$$\text{Rate} = k[\text{NO}_2]^2$$

Thus, the overall reaction cannot be elementary.

A proposed two-step mechanism is

In this mechanism,  $\text{NO}_3$  functions as a **reaction intermediate**, a substance formed in one step of the mechanism and used up in a subsequent step during the reaction. Even though it does not appear in the overall balanced equation, a reaction intermediate is essential for the reaction to occur. Intermediates are less stable than the reactants and products, but unlike *much* less stable transition states, they have normal bonds and can sometimes be isolated.

Rate laws for the two elementary steps listed above are

Three key points to notice about this mechanism are

- If  $k_1 = k$ , the rate law for the rate-determining step (step 1) becomes identical to the observed rate law.

### A Rate-Determining Step for Traffic Flow

Imagine driving home on a wide street that goes over a toll bridge. Traffic flows smoothly until the road narrows at the approach to the toll booth. Past the bridge, traffic returns to normal, and you proceed a couple of miles further to your destination. Getting through the bottleneck to pay the toll takes longer than the rest of the trip combined and, therefore, largely determines the time for the whole trip.

- Because the first step is slow,  $[\text{NO}_3]$  is low. As soon as any  $\text{NO}_3$  forms, it is consumed by the fast second step, so the reaction takes as long as the first step does.
- $\text{CO}$  does not appear in the rate law (reaction order = 0) because it takes part in the mechanism *after* the rate-determining step and so its concentration does not affect the rate.

## Correlating the Mechanism with the Rate Law

Coming up with a reasonable reaction mechanism is a classic demonstration of the scientific method. Using observations and data from rate experiments, we hypothesize the individual steps and then test our hypothesis with further evidence. If the evidence supports our mechanism, we can accept it; if not, we must propose a different one. We can never *prove* that a mechanism represents the *actual* chemical change, only that it is consistent with the data.

A valid mechanism must meet three criteria:

1. *The elementary steps must add up to the overall balanced equation.*
2. *The elementary steps must be reasonable.* They should generally involve one reactant particle (unimolecular) or two (bimolecular).
3. *The mechanism must correlate with the rate law, not the other way around.*

**Mechanisms with a Slow Initial Step** The reaction between  $\text{NO}_2$  and  $\text{CO}$  that we considered earlier has a mechanism with a slow initial step; that is, the first step is rate-determining. The reaction between nitrogen dioxide and fluorine is another example of such a reaction:

The experimental rate law is first order in  $\text{NO}_2$  and in  $\text{F}_2$ ,

$$\text{Rate} = k[\text{NO}_2][\text{F}_2]$$

and the accepted mechanism is

Note that the free fluorine atom is a reaction intermediate.

Let's see how this mechanism meets the three criteria.

1. The elementary reactions sum to the balanced equation:

or

2. Both steps are bimolecular and, thus, reasonable.
3. To determine whether the mechanism is consistent with the observed rate law, we first write the rate laws for the elementary steps:

$$(1) \text{Rate}_1 = k_1[\text{NO}_2][\text{F}_2]$$

$$(2) \text{Rate}_2 = k_2[\text{NO}_2][\text{F}]$$

Step 1 is the rate-determining step, and with  $k_1 = k$ , it is the same as the overall rate law, so the third criterion is met.

Note that the second molecule of  $\text{NO}_2$  is involved *after* the rate-determining step, so it does not appear in the overall rate law. Thus, as in the mechanism for the reaction of  $\text{NO}_2$  and  $\text{CO}$ , *the overall rate law includes all the reactants involved in the rate-determining step.*

**Mechanisms with a Fast Initial Step** If the rate-limiting step in a mechanism is *not* the initial step, the product of the fast initial step builds up and starts reverting to reactant. With time, this *fast, reversible step reaches equilibrium*, as product changes to reactant as fast as it forms. As you'll see, this situation allows us to fit the mechanism to the overall rate law.

Consider the oxidation of nitrogen monoxide:

The observed rate law is

$$\text{Rate} = k[\text{NO}]^2[\text{O}_2]$$

and a proposed mechanism is

Let's go through the three criteria to see if this mechanism is valid.

1. With cancellation of the reaction intermediate,  $\text{NO}_3$ , the sum of the steps gives the overall equation, so the first criterion is met:

2. Both steps are bimolecular, so the second criterion is met.
3. To see whether the third criterion—that the mechanism is consistent with the observed rate law—is met, we first write rate laws for the elementary steps:

$$(1) \text{Rate}_{1(\text{fwd})} = k_1[\text{NO}][\text{O}_2]$$

$$\text{Rate}_{1(\text{rev})} = k_{-1}[\text{NO}_3]$$

where  $k_{-1}$  is the rate constant and  $\text{NO}_3$  is the reactant for the reverse reaction.

$$(2) \text{Rate}_2 = k_2[\text{NO}_3][\text{NO}]$$

Next, we show that the rate law for the rate-determining step (step 2) gives the overall rate law. As written, it does not, because it contains the intermediate  $\text{NO}_3$ , and *an overall rate law includes only reactants (and products)*. We eliminate  $[\text{NO}_3]$  from the rate law for step 2 by expressing it in terms of reactants, as follows.

- Step 1 reaches equilibrium when the forward and reverse rates are equal:

$$\text{Rate}_{1(\text{fwd})} = \text{Rate}_{1(\text{rev})} \quad \text{or} \quad k_1[\text{NO}][\text{O}_2] = k_{-1}[\text{NO}_3]$$

- To express  $[\text{NO}_3]$  in terms of reactants, we isolate it algebraically:

$$[\text{NO}_3] = \frac{k_1}{k_{-1}} [\text{NO}][\text{O}_2]$$

- Then, substituting for  $[\text{NO}_3]$  in the rate law for the slow step, step 2, we obtain

$$\text{Rate}_2 = k_2[\text{NO}_3][\text{NO}] = k_2 \left( \frac{k_1}{k_{-1}} [\text{NO}][\text{O}_2] \right) [\text{NO}] = \frac{k_2 k_1}{k_{-1}} [\text{NO}]^2 [\text{O}_2]$$

With  $k = \frac{k_2 k_1}{k_{-1}}$ , this rate law is identical to the overall rate law.

To summarize, we assess the validity of a mechanism with a fast initial step by

1. Writing rate laws for the fast step (both directions) and for the slow step.
2. Expressing [intermediate] in terms of [reactant] by setting the forward rate law of the reversible step equal to the reverse rate law, and solving for [intermediate].
3. Substituting the expression for [intermediate] into the rate law for the slow step to obtain the overall rate law.

An important point to note is that, *for any mechanism, only reactants involved up to and including the slow (rate-determining) step appear in the overall rate law.*

### Student Hot Spot

Student data indicate that you may struggle with the concept of reaction mechanisms. Access the Smartbook to view additional Learning Resources on this topic.

#### SAMPLE PROBLEM 16.11

#### Identifying Intermediates and Correlating Rate Laws and Reaction Mechanisms

**Problem** Consider the reaction mechanism in Sample Problem 16.10.

- (a) Identify the intermediates in the mechanism.
- (b) Assuming that step 2 is the slow (rate-determining) step, show that the mechanism is consistent with the observed rate law:  $\text{Rate} = k[\text{Cl}_2]^{1/2}[\text{CHCl}_3]$ .

**Plan** (a) We write each elementary step and sum to get the overall reaction. Intermediates are substances that are produced in one elementary step and consumed as reactants in a subsequent elementary step. (b) We use the reactants in the slow step to write its rate law; if an intermediate is present in the rate law, we eliminate it by expressing it in terms of reactants.

**Solution (a)** Determining the intermediates:

Cl and CCl<sub>3</sub> are formed and used up, so the intermediates are Cl(g) and CCl<sub>3</sub>(g).

**(b)** Correlating the reaction mechanism and the rate law:

Step 2 is the rate-determining step:

Since it is an intermediate, [Cl] must be expressed in terms of reactants:

$$\text{From step 1: Rate}_{1(\text{fwd})} = \text{Rate}_{1(\text{rev})} \quad \text{or} \quad k_1[\text{Cl}_2] = k_{-1}[\text{Cl}]^2$$

Thus,

$$[\text{Cl}]^2 = \frac{k_1}{k_{-1}}[\text{Cl}_2] \quad \text{and} \quad [\text{Cl}] = \sqrt{\frac{k_1}{k_{-1}}[\text{Cl}_2]} = \sqrt{\frac{k_1}{k_{-1}}}[\text{Cl}_2]^{1/2}$$

Substituting for [Cl] in the rate law for the slow step:

$$\text{Rate} = k_2[\text{Cl}][\text{CHCl}_3] = k_2 \sqrt{\frac{k_1}{k_{-1}}}[\text{Cl}_2]^{1/2}[\text{CHCl}_3]$$

With  $k = k_2 \sqrt{\frac{k_1}{k_{-1}}}$ , this rate law is consistent with the observed rate law.

**Check** Be sure that the substances identified as intermediates are not included in the overall balanced equation. In part (b), be sure that the rate-determining step is used to write the rate law and that no intermediates are included in the rate law.

### FOLLOW-UP PROBLEMS

**16.11A** Examine the reaction mechanism in Follow-up Problem 16.10A. **(a)** Identify the intermediates in the mechanism. **(b)** The observed rate law for the decomposition of hydrogen peroxide is  $\text{Rate} = k[\text{H}_2\text{O}_2]$ . For the reaction mechanism to be consistent with this rate law, which step must be the rate-determining step?

**16.11B** The observed rate law for the overall reaction whose mechanism is shown in Follow-up Problem 16.10B is  $\text{Rate} = k[\text{NO}]^2[\text{H}_2]$ . **(a)** Identify the intermediates in this mechanism. **(b)** Assuming that step 2 is the slow (rate-determining) step, show that this mechanism is consistent with the observed rate law.

**SOME SIMILAR PROBLEMS** 16.74(b), 16.74(d), 16.74(e), 16.75(b), and 16.75(d)

**Using the Steady-State Approximation** Another approach to determining the rate law from a mechanism is to use the **steady-state approximation**, which assumes that the concentration of an intermediate is essentially constant because it is produced in one step of the mechanism at the same rate it is consumed in another step. Let's apply the steady-state approximation to the oxidation of nitrogen monoxide that we previously examined,

with the following proposed mechanism:

The rate of NO<sub>2</sub> production is given by the second step of the mechanism, with  $k_2$  as the rate constant:

$$\text{Rate of NO}_2 \text{ production} = k_2[\text{NO}_3][\text{NO}]$$

We must eliminate the  $\text{NO}_3$  intermediate from this expression. First, we write the expression for the *net* rate of formation of  $\text{NO}_3$ . It is produced in the forward reaction of step 1 at a rate of  $k_1[\text{NO}][\text{O}_2]$ , consumed in the reverse reaction of step 1 at a rate of  $k_{-1}[\text{NO}_3]$ , and consumed in step 2 at a rate of  $k_2[\text{NO}_3][\text{NO}]$ . Therefore, the net rate of  $\text{NO}_3$  formation is the difference between the rate of production and the rates of consumption:

$$\text{Net rate of } \text{NO}_3 \text{ formation} = \underset{\substack{\text{production in} \\ \text{step 1} \\ \text{(forward} \\ \text{reaction)}}}{k_1[\text{NO}][\text{O}_2]} - \underset{\substack{\text{consumption} \\ \text{in step 1} \\ \text{(reverse} \\ \text{reaction)}}}{k_{-1}[\text{NO}_3]} - \underset{\text{consumption in step 2}}{k_2[\text{NO}_3][\text{NO}]}$$

At this point, we make the steady-state approximation that  $[\text{NO}_3]$  remains constant during the reaction, so that its net rate of formation is zero and the previous equation becomes

$$\text{Net rate of } \text{NO}_3 \text{ formation} = 0 = k_1[\text{NO}][\text{O}_2] - k_{-1}[\text{NO}_3] - k_2[\text{NO}_3][\text{NO}]$$

We can rearrange this equation to obtain an expression for  $[\text{NO}_3]$ :

$$k_1[\text{NO}][\text{O}_2] = k_{-1}[\text{NO}_3] + k_2[\text{NO}_3][\text{NO}]$$

$$k_1[\text{NO}][\text{O}_2] = [\text{NO}_3](k_{-1} + k_2[\text{NO}])$$

$$\frac{k_1[\text{NO}][\text{O}_2]}{k_{-1} + k_2[\text{NO}]} = [\text{NO}_3]$$

Substituting this expression for  $[\text{NO}_3]$  into the rate law for the production of  $\text{NO}_2$  gives

$$\text{Rate of } \text{NO}_2 \text{ production} = k_2[\text{NO}_3][\text{NO}] = \frac{k_1 k_2 [\text{NO}]^2 [\text{O}_2]}{k_{-1} + k_2 [\text{NO}]}$$

At first, this expression seems to differ from the observed rate law, which is rate =  $k[\text{NO}]^2[\text{O}_2]$ . But, recall that step 2 is slow relative to step 1, which means that  $k_2 \ll k_{-1}$ , so  $k_2[\text{NO}] \ll k_{-1}$  and can be ignored. Thus, we have

$$\text{Rate of } \text{NO}_2 \text{ production} = \frac{k_1 k_2}{k_{-1}} [\text{NO}]^2 [\text{O}_2] = k [\text{NO}]^2 [\text{O}_2]$$

As you can see, with  $k = \frac{k_1 k_2}{k_{-1}}$ , the expression becomes the same as the observed rate law. The steady-state approximation method is also useful with mechanisms in which there is no single rate-determining step.

**Depicting a Multistep Mechanism with a Reaction Energy Diagram** Figure 16.22 shows reaction energy diagrams for two reactions, each of which has a two-step mechanism, shown below the diagram. The reaction of  $\text{NO}_2$  and  $\text{F}_2$  (part A) starts with a slow step, and the reaction of  $\text{NO}$  and  $\text{O}_2$  (part B) starts with a fast step. Both overall reactions are exothermic, so the product is lower in energy than the reactants. Note these key points:

- Each step in the mechanism has its own peak with the transition state at the top.
- The intermediates (F in part A and  $\text{NO}_3$  in part B) are reactive, unstable species, so they are higher in energy than the reactants or product.
- The slow (rate-determining) step (step 1 in A and step 2 in B) has a larger  $E_a$  than the other step.

## › Summary of Section 16.6

- › The mechanisms of most common reactions consist of two or more elementary steps, each of which describes a single molecular event.
- › The molecularity of an elementary step equals the number of reactant particles and is the same as the total reaction order of the step. Only unimolecular and bimolecular steps are reasonable.
- › The rate-determining (slowest) step in a mechanism determines how fast the overall reaction occurs, and its rate law is equivalent to the overall rate law.

**Figure 16.22** Reaction energy diagrams for the two-step reaction of (A)  $\text{NO}_2$  and  $\text{F}_2$  and of (B)  $\text{NO}$  and  $\text{O}_2$ .

- › Reaction intermediates are species that form in one step and react in a later one.
- › For a mechanism to be valid, (1) the elementary steps must add up to the overall balanced equation, (2) the steps must be reasonable, and (3) the mechanism must correlate with the rate law.
- › If a mechanism begins with a slow step, only those reactants involved in the slow step appear in the overall rate law.
- › If a mechanism begins with a fast step, the product of the fast step accumulates as an intermediate, and the step reaches equilibrium. To show that the mechanism is valid, we express [intermediate] in terms of [reactant]. In some cases, we use the steady-state approximation, which assumes that [intermediate] is constant, to see if the mechanism is consistent with the rate law.
- › Only reactants involved in steps up to and including the slow (rate-determining) step appear in the overall rate law.
- › Each step in a mechanism has its own transition state, which appears at the top of a peak in the reaction energy diagram. A slower step has a higher peak (larger  $E_a$ ).

## 16.7 CATALYSIS: SPEEDING UP A REACTION

Increasing the rate of a reaction has countless applications, in both engineering and biology. Higher temperature can speed up a reaction, but energy for industrial processes is costly and many organic and biological substances are heat sensitive. More commonly, by far, a reaction is accelerated by a **catalyst**, a substance that increases the reaction rate *without* being consumed. Thus, only a small, nonstoichiometric amount of the catalyst is required to speed the reaction. Despite this, catalysts are employed in so many processes that several million tons are produced annually in the United States alone. Nature is the master designer and user of catalysts: every organism relies on protein catalysts, known as *enzymes*, to speed up life-sustaining reactions, and even the simplest bacterium employs thousands of them.

**Figure 16.23** Reaction energy diagram for a catalyzed (green) and an uncatalyzed (red) process. A catalyst speeds a reaction by providing a different, lower energy pathway (green). (Only the first step of the catalyzed reverse reaction is labeled.)

## The Basis of Catalytic Action

Each catalyst has its own specific way of functioning, but in general, a catalyst provides a different reaction mechanism with a lower activation energy, which in turn makes the rate constant larger and, thus, the reaction rate higher:

Consider a general *uncatalyzed* reaction that proceeds by a one-step mechanism involving a bimolecular collision between the reactants A and B (Figure 16.23). The activation energy is relatively large, so the rate is relatively low:

In the *catalyzed* reaction, reactant A interacts with the catalyst in one step to form the intermediate C, and then C reacts with B in a second step to form product and regenerate the catalyst:

Three points to note in Figure 16.23 are

- A catalyst speeds up the forward *and* reverse reactions. Thus, a reaction has the *same yield* with or without a catalyst, but the product forms *faster*.
- A catalyst causes a *lower total activation energy* by providing a *different mechanism* for the reaction. The total of the activation energies for both steps of the catalyzed pathway [ $E_{a1(\text{fwd})} + E_{a2(\text{fwd})}$ ] is less than the forward activation energy of the uncatalyzed pathway.
- The catalyst is *not* consumed, but rather used and then regenerated.

## Homogeneous Catalysis

Chemists classify catalysts based on whether or not they act in the same phase as the reactants and products. A **homogeneous catalyst** exists in solution with the reaction mixture, so it must be a gas, liquid, or soluble solid.

A thoroughly studied example of homogeneous catalysis in the gas phase was formerly used in sulfuric acid manufacture. The key step, the oxidation of sulfur dioxide to sulfur trioxide, occurs so slowly that it is not economical:

In the presence of nitrogen monoxide, however, the overall reaction rate speeds up dramatically:

Note that NO and NO<sub>2</sub> cancel to give the overall reaction:

- NO<sub>2</sub> acts as an intermediate (formed in the first step and then consumed in the second step) and
- NO acts as a catalyst (used in the first step and then regenerated in the second step).

Another well-studied example of homogeneous catalysis involves the decomposition of hydrogen peroxide in aqueous solution:

Commercial H<sub>2</sub>O<sub>2</sub> decomposes in light and in the presence of the small amounts of ions dissolved from glass, but it is quite stable in dark plastic containers. Many other substances speed its decomposition, including bromide ion, Br<sup>-</sup> (Figure 16.24). The catalyzed process is thought to occur in two steps, both of which are oxidation-reduction reactions:

In this case, Br<sub>2</sub>, Br<sup>-</sup>, and H<sup>+</sup> cancel to give the overall balanced equation:

- Br<sup>-</sup> (in the presence of H<sup>+</sup>) is the catalyst, and
- Br<sub>2</sub> (which is orange in color) is the intermediate.

## Heterogeneous Catalysis

A **heterogeneous catalyst** speeds up a reaction in a different phase. Most often solids interacting with gaseous or liquid reactants, these catalysts have enormous surface areas, sometimes as much as 500 m<sup>2</sup>/g. Very early in the reaction, the rate depends on reactant concentration, but almost immediately, the reaction becomes zero order: the rate-determining step occurs on the catalyst's surface, so once the reactant covers it, adding more reactant cannot increase the rate further.

A very important organic example of heterogeneous catalysis is used to speed up **hydrogenation**, the addition of H<sub>2</sub> to C=C bonds to form C—C bonds. The petroleum, plastics, and food industries employ this process on an enormous scale. The simplest hydrogenation converts ethylene (ethene) to ethane:

In the absence of a catalyst, the reaction is very slow. But, at high H<sub>2</sub> pressure (high [H<sub>2</sub>]) and in the presence of finely divided Ni, Pd, or Pt metal, it is rapid even at ordinary temperatures. The Group 8B(10) metals catalyze by *chemically adsorbing the reactants onto their surface* (Figure 16.25, next page). In the rate-determining step, the adsorbed H<sub>2</sub> splits into two H atoms that become weakly bonded to the catalyst's surface (catM):

Then, C<sub>2</sub>H<sub>4</sub> adsorbs and reacts with the H atoms, one at a time, to form C<sub>2</sub>H<sub>6</sub>. Thus, the catalyst acts by lowering the activation energy of the slow step (H—H bond breakage) as part of a different mechanism.

A solid mixture of transition metals and their oxides forms a heterogeneous catalyst in your car's exhaust system. The catalytic converter speeds both the oxidation of toxic CO and unburned gasoline to CO<sub>2</sub> and H<sub>2</sub>O and the reduction of the pollutant

**Figure 16.25** The metal-catalyzed hydrogenation of ethene.

NO to  $N_2$ . As in the hydrogenation mechanism, the catalyst adsorbs the molecules, which weakens and splits their bonds, thus allowing the atoms to form new bonds more quickly. The process is extremely efficient: for example, an NO molecule is split into catalyst-bound N and O atoms in less than  $2 \times 10^{-12}$  s.

### Kinetics and Function of Biological Catalysts

Whereas most industrial chemical reactions occur under extreme conditions with high concentrations, thousands of complex reactions occur in every living cell in dilute solution at ordinary temperatures and pressures. Moreover, the rate of each reaction responds to the rates of other reactions, chemical signals from other cells, and environmental stress. In this marvelous chemical harmony, each rate is controlled by an **enzyme**, a protein catalyst whose function has been perfected through evolution.

Enzymes are typically globular proteins with complex shapes (Section 15.6) and molar masses ranging from about 15,000 to 1,000,000 g/mol. A small part of an enzyme's surface—like a hollow carved into a mountainside—is the **active site**, a region whose shape results from the amino-acid side chains involved in catalyzing the reaction. Often far apart in the sequence of the polypeptide chain, these groups lie near each other because of the chain's three-dimensional folding. When the reactant molecules, called **substrates**, collide effectively with the active site, they become attached through *intermolecular forces*, and the chemical change begins.

**Characteristics of Enzyme Action** The catalytic behavior of enzymes has several common features:

1. **Catalytic activity.** An enzyme behaves like both types of catalyst. Enzymes are typically *much* larger than the substrate, and many enzymes are embedded within cell membranes. Thus, like a heterogeneous catalyst, an enzyme provides a surface on which one reactant is temporarily immobilized to wait until the other reactant lands nearby. But, like many homogeneous catalysts, the active site groups interact with the substrate(s) in multistep sequences in the presence of solvent and other species.
2. **Catalytic efficiency.** Enzymes are incredibly *efficient* in terms of the number of reactions catalyzed per unit time. For example, for the hydrolysis of urea,

the rate constant is  $3 \times 10^{-10} \text{ s}^{-1}$  for the uncatalyzed reaction in water at room temperature. Under the same conditions in the presence of the enzyme *urease* (pronounced “YUR-ee-ase”), the rate constant is  $3 \times 10^4 \text{ s}^{-1}$ , a  $10^{14}$ -fold increase.

**Figure 16.26** Two models of enzyme action.

Enzymes typically increase rates by  $10^8$  to  $10^{20}$  times, values that industrial chemists who use catalysts can only dream of!

3. *Catalytic specificity.* As a result of the particular groups at the active site, enzymes are also highly *specific*: each enzyme generally catalyzes only one reaction. Urease catalyzes *only* the hydrolysis of urea, and no other enzyme does this.

**Models of Enzyme Action** Two models of enzyme action have been proposed.

1. According to the older **lock-and-key model** (Figure 16.26A), when the “key” (substrate) fits the “lock” (active site), the chemical change begins.
2. According to the more current **induced-fit model** (Figure 16.26B), the substrate induces the active site to adopt a perfect fit. X-ray crystallographic and spectroscopic methods show that, in most cases, *the enzyme changes shape when the substrate lands at the active site*. Rather than a rigid key in a lock, we picture a flexible hand in a glove; the “glove” (active site) does not attain its functional shape until the “hand” (substrate) moves into it.

**Kinetics of Enzyme Action** Understanding the kinetics of enzyme catalysis relies on the steady-state approximation (Section 16.6) in a mechanism proposed by Leonor Michaelis (1875–1949) and Maud Menten (1879–1960) in 1913:

- (1)  $E + S \rightleftharpoons ES$  [fast, reversible]
- (2)  $ES \rightarrow E + P$  [slow; rate-determining]

In the first step, substrate (S) and enzyme (E) form an intermediate **enzyme-substrate complex (ES)**, which breaks down to form product (P) and enzyme in the second step. Thus, the rate is proportional to the concentration of ES, that is, of reactant bound to catalyst:

$$\text{Rate} = k_2[ES]$$

where  $k_2$  is the rate constant of step 2. Let’s use the steady-state approximation to eliminate the intermediate concentration, [ES], from this rate law. ES is produced in the forward reaction of step 1 (with rate constant =  $k_1$ ), consumed in the reverse reaction of step 1 (with rate constant =  $k_{-1}$ ), and consumed in step 2. From the approximation, the net rate of ES production is zero:

$$\frac{d[ES]}{dt} = 0 = k_1[E][S] - k_{-1}[ES] - k_2[ES]$$

The concentration of free enzyme, [E], is difficult to measure, but we can determine it by noting that the initial, measured amount of enzyme,  $E_0$ , must equal the sum of E and ES. Therefore,  $[E]_0 = [E] + [ES]$ , and solving for [E] gives

$$[E] = [E]_0 - [ES]$$

Substituting this concentration into the expression for the net rate of ES production gives

$$\frac{d[ES]}{dt} = 0 = k_1([E]_0 - [ES])[S] - k_{-1}[ES] - k_2[ES]$$

**Figure 16.27** Plot of the initial rate of an enzyme-catalyzed reaction versus substrate concentration

Carrying out the arithmetic gives

$$\frac{d[\text{ES}]}{dt} = 0 = k_1[\text{E}]_0[\text{S}] - k_1[\text{ES}][\text{S}] - k_{-1}[\text{ES}] - k_2[\text{ES}]$$

Solving this equation for [ES] gives

$$[\text{ES}] = \frac{k_1[\text{E}]_0[\text{S}]}{k_{-1} + k_2 + k_1[\text{S}]} = \frac{[\text{E}]_0[\text{S}]}{K_M + [\text{S}]}$$

where  $K_M = \frac{k_{-1} + k_2}{k_1}$  and is referred to as the **Michaelis constant**. Substituting the expression for [ES] into the rate law for the formation of product gives the **Michaelis-Menten equation** for enzyme kinetics:

$$\text{Rate} = k_2[\text{ES}] = \frac{k_2[\text{E}]_0[\text{S}]}{K_M + [\text{S}]} \quad (16.11)$$

The Michaelis-Menten equation shows that the rate of reaction is always first order in the initial concentration of enzyme,  $[\text{E}]_0$ . Figure 16.27 shows the relationship between rate and substrate concentration. Two portions of the plot are important:

- When [S] is low, such that  $[\text{S}] \ll K_M$ , Equation 16.11 simplifies to

$$\text{Rate} = \frac{k_2}{K_M}[\text{E}]_0[\text{S}]$$

and the rate is first order in [S], as shown by the rising, linear portion of the plot. As more S is added, more ES forms, so more P forms as well.

- When [S] is high, such that  $[\text{S}] \gg K_M$ , Equation 16.11 simplifies to

$$\text{Rate} = k_2[\text{E}]_0$$

and the rate becomes independent of substrate concentration; that is, the reaction is zero order in [S]. When all the enzyme molecules are bound to substrate, [ES] is as high as possible, so adding more S has no effect on rate, as shown by the horizontal leveling off of the plot.

By taking the inverse of both sides of Equation 16.11, we get

$$\frac{1}{\text{rate}} = \frac{K_M}{k_2[\text{E}]_0[\text{S}]} + \frac{1}{k_2[\text{E}]_0}$$

$$y = mx + b$$

**Figure 16.28** Graphical determination of the Michaelis constant.

Figure 16.28 shows that a plot of  $1/\text{rate}$  vs.  $1/[\text{S}]$  gives a straight line with the slope,  $m = \frac{K_M}{k_2[\text{E}]_0}$  and  $y$ -intercept,  $b = \frac{1}{k_2[\text{E}]_0}$ , from which we can solve for the Michaelis constant,  $K_M$ .

**Mechanisms of Enzyme Action** Enzymes employ a variety of reaction mechanisms. In some cases, the active site groups bring specific atoms of the substrate close together. In others, the groups bound to the substrate move apart, stretching the bond to be broken. Many *hydrolases* have acidic groups that provide  $\text{H}^+$  ions to speed bond cleavage. Two examples are lysozyme, an enzyme found in tears, which hydrolyzes a polysaccharide in bacterial cell walls to protect the eyes from infection, and chymotrypsin, an enzyme found in the small intestine, which hydrolyzes proteins during digestion.

No matter what their mode of action, *all enzymes catalyze by stabilizing the reaction's transition state*. For instance, in the lysozyme-catalyzed reaction, the transition state is a portion of the polysaccharide whose bonds have been twisted and stretched by the active site groups until it fits the active site well. Stabilizing the transition state lowers the activation energy and thus increases the rate.

Like enzyme-catalyzed reactions, the process of stratospheric ozone depletion, discussed in the following Chemical Connections essay, includes both homogeneous and heterogeneous catalysis.

The stratospheric ozone layer absorbs UV radiation that is emitted by the Sun and has wavelengths between 280 and 320 nm. If it reaches Earth's surface, this radiation has enough energy to damage genes by breaking bonds in DNA. Thus, depletion of stratospheric ozone increases human health risks, particularly the risks of skin cancer and cataracts (clouding of the eye's lens). The radiation may also damage plant life, especially forms at the bottom of the food chain. Both homogeneous and heterogeneous catalysts play roles in the depletion of ozone.

Before 1976, stratospheric ozone concentration varied seasonally but remained nearly constant from year to year as a result of a series of atmospheric reactions:

Then, in 1985, British scientists reported that a severe reduction of ozone, an *ozone hole*, appeared in the stratosphere over the Antarctic when the Sun ended the long winter darkness. Subsequent research by Paul J. Crutzen, Mario J. Molina, and F. Sherwood Rowland, for which they received the Nobel Prize in chemistry in 1995, revealed that industrial chlorofluorocarbons (CFCs) were lowering  $[\text{O}_3]$  in the stratosphere by catalyzing the reaction in which ozone is broken down.

Widely used as aerosol propellants, foaming agents, and air-conditioning coolants, large quantities of CFCs were released for years. Unreactive in the troposphere, CFC molecules gradually reach the stratosphere, where UV radiation splits them:

(The dots are lone electrons resulting from C—Cl bond cleavage.)

Like many species with a lone electron (free radicals), atomic Cl is very reactive. It reacts with stratospheric  $\text{O}_3$  to produce the

intermediate chlorine monoxide ( $\text{ClO}\cdot$ ), which then reacts with a free O atom to regenerate a Cl atom:

The sum of these steps is the ozone breakdown reaction:

Studies finding high  $[\text{ClO}\cdot]$  over Antarctica supported this mechanism. Figure B16.1 shows the ozone hole expanding over the years in which CFCs accumulated.

Figure B16.2 shows the reaction energy diagram for the process. Note that *chlorine acts as a homogeneous catalyst*: it exists in the same phase as the reactants, lowers the total activation energy via a different mechanism, and is regenerated. Each Cl atom has a stratospheric half-life of about 2 years, during which it speeds the breakdown of about 100,000 ozone molecules.

Later studies showed that the ozone hole enlarges by heterogeneous catalysis. Stratospheric clouds provide a surface for reactions that convert inactive chlorine compounds, such as HCl and chlorine nitrate ( $\text{ClONO}_2$ ), to substances, such as  $\text{Cl}_2$ , that are cleaved by UV radiation to Cl atoms. Fine particles in the stratosphere act in the same way: dust from the 1991 eruption of Mt. Pinatubo reduced stratospheric ozone for 2 years. The Montreal Protocol of 1987 and later amendments curtailed CFC production and proposed substituting hydrocarbon propellants, such as isobutane,  $(\text{CH}_3)_3\text{CH}$ . Nevertheless, because of the long lifetimes of CFCs, complete recovery of the ozone layer may take another century! The good news is that tropospheric halogen levels have begun to fall.

(continued)

## Problems

**B16.1** The catalytic destruction of ozone occurs via a two-step mechanism, where X can be one of several species:

(a) Write the overall reaction and the rate law for each step.

(b) X acts as \_\_\_\_\_, and XO acts as \_\_\_\_\_.

**B16.2** Aircraft in the stratosphere release NO, which catalyzes ozone breakdown by the mechanism shown in Problem B16.1.

(a) Write the mechanism.

(b) What is the rate of  $\text{O}_3$  depletion ( $k$  for the rate-determining step is  $6 \times 10^{-15} \text{ cm}^3/\text{molecule}\cdot\text{s}$ ) when  $[\text{O}_3]$  is  $5 \times 10^{12} \text{ molecules/cm}^3$  and  $[\text{NO}]$  is  $1.0 \times 10^9 \text{ molecules/cm}^3$ ?

**B16.3** In the mechanism for  $\text{O}_3$  breakdown in Problem B16.1:

(a) Which would you expect to have a higher value for the orientation probability factor,  $p$ , step 1 with NO or step 1 with Cl? Explain.

(b) Draw a possible transition state for the step with Cl.

## › Summary of Section 16.7

- › A catalyst increases the rate of a reaction without being consumed. It accomplishes this by providing another mechanism that has a lower activation energy.
- › Homogeneous catalysts function in the same phase as the reactants. Heterogeneous catalysts act in a different phase from the reactants.
- › The hydrogenation of carbon-carbon double bonds takes place on a solid metal catalyst, which speeds up the rate-determining step, the breakage of the  $\text{H}_2$  bond.
- › Enzymes are protein catalysts of high efficiency and specificity that act by stabilizing the transition state and, thus, lowering the activation energy. The rate of an enzyme-catalyzed reaction is first order in substrate concentration,  $[\text{S}]$ , at low  $[\text{S}]$  and zero order at high  $[\text{S}]$ .
- › Chlorine atoms from CFC molecules speed the breakdown of stratospheric  $\text{O}_3$  in a process that is affected by both homogeneous and heterogeneous catalysis.

## CHAPTER REVIEW GUIDE

### Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

#### Understand These Concepts

1. How reaction rate depends on concentration, physical state, and temperature (§16.1)
2. The meaning of *reaction rate* in terms of changing concentrations over time (§16.2)
3. How the rate can be expressed in terms of reactant or product concentrations (§16.2)
4. The distinction between average and instantaneous rate and why the instantaneous rate changes during a reaction (§16.2)
5. The interpretation of a reaction rate in terms of reactant and product concentrations (§16.2)
6. The experimental basis of the rate law and the information needed to determine it—initial rate data, reaction orders, and rate constant (§16.3)
7. The importance of reaction order in determining the rate (§16.3)
8. How reaction order is determined from initial rates at different concentrations (§16.3)
9. How integrated rate laws show the dependence of concentration on time (§16.4)
10. What reaction half-life means and why it is constant for a first-order reaction (§16.4)
11. Why concentrations are multiplied in the rate law (§16.5)
12. Activation energy and the effect of temperature on the rate constant (Arrhenius equation) (§16.5)
13. How temperature affects rate by influencing collision energy and, thus, the fraction of collisions with energy exceeding the activation energy (§16.5)
14. Why molecular orientation and complexity influence the number of effective collisions and the rate (§16.5)
15. The transition state as the species that exists only momentarily between reactants and products and whose formation requires the activation energy (§16.5)
16. How an elementary step represents a single molecular event and its molecularity equals the number of colliding particles (§16.6)
17. How a reaction mechanism consists of several elementary steps, with the slowest step determining the overall rate (§16.6)

- The criteria for a valid reaction mechanism (§16.6)
- How the steady-state approximation can be used to determine a rate law from a reaction mechanism (16.6)
- How a catalyst speeds a reaction by lowering the activation energy (§16.7)
- The distinction between homogeneous and heterogeneous catalysis (§16.7)
- How the steady-state approximation can be used to understand enzyme kinetics (16.7)
- Calculating the rate constant and its units (§16.3 and SP 16.3)
- Using an integrated rate law to find concentration at a given time or the time to reach a given concentration (SP 16.5)
- Determining reaction order graphically with a rearranged integrated rate law (§16.4)
- Determining the half-life of a reaction (SPs 16.6, 16.7)
- Using a form of the Arrhenius equation to calculate the activation energy (SP 16.8)
- Using reaction energy diagrams to depict the energy changes during a reaction (SP 16.9)
- Predicting a transition state for a simple reaction (SP 16.9)
- Determining the molecularity and rate law for an elementary step (SP 16.10)
- Constructing a mechanism with either a slow or a fast initial step (§16.6)
- Identifying intermediates and correlating rate laws and reaction mechanisms (SP 16.11)

### Master These Skills

- Calculating the instantaneous rate from the slope of a tangent to a concentration vs. time plot (§16.2)
- Expressing reaction rate in terms of changes in concentration with time (SP 16.1)
- Determining reaction order from a known rate law (SP 16.2)
- Determining reaction orders from rate data or molecular scenes (SPs 16.3, 16.4)

### Key Terms

Page numbers appear in parentheses.

activation energy ( $E_a$ ) (716)	enzyme-substrate complex (ES) (733)	Michaelis constant (734)	reaction mechanism (722)
active site (732)	frequency factor (719)	Michaelis-Menten equation (734)	reaction orders (699)
Arrhenius equation (716)	half-life ( $t_{1/2}$ ) (712)	molecularity (723)	reaction rate (691)
average rate (695)	heterogeneous catalyst (731)	pseudo-first-order (709)	steady-state approximation (727)
bimolecular reaction (723)	homogeneous catalyst (730)	rate constant (698)	substrate (732)
catalyst (729)	hydrogenation (731)	rate-determining (rate-limiting) step (724)	transition state (activated complex) (719)
chemical kinetics (691)	induced-fit model (733)	rate law (rate equation) (698)	transition state theory (719)
collision theory (716)	initial rate (696)	reaction energy diagram (720)	unimolecular reaction (723)
effective collision (719)	instantaneous rate (695)	reaction intermediate (724)	
elementary reaction (elementary step) (722)	integrated rate law (708)		
enzyme (732)	lock-and-key model (733)		

### Key Equations and Relationships

Page numbers appear in parentheses.

**16.1** Expressing reaction rate in terms of reactant A (694):

$$\text{Rate} = -\frac{\Delta[A]}{\Delta t}$$

**16.2** Expressing the rate of a general reaction (697):

$$\text{Rate} = -\frac{1}{a} \frac{d[A]}{dt} = -\frac{1}{b} \frac{d[B]}{dt} = \frac{1}{c} \frac{d[C]}{dt} = \frac{1}{d} \frac{d[D]}{dt}$$

**16.3** Writing a general rate law (in which products do not appear) (698):

$$\text{Rate} = k[A]^m[B]^n \dots$$

**16.4** Calculating the time to reach a given [A] for a first-order reaction (rate =  $k[A]$ ) (708):

$$\ln \frac{[A]_0}{[A]_t} = kt$$

**16.5** Calculating the time to reach a given [A] for a simple second-order reaction (rate =  $k[A]^2$ ) (709):

$$\frac{1}{[A]_t} - \frac{1}{[A]_0} = kt$$

**16.6** Calculating the time to reach a given [A] for a zero-order reaction (rate =  $k$ ) (709):

$$[A]_t - [A]_0 = -kt$$

**16.7** Finding the half-life of a first-order process (712):

$$t_{1/2} = \frac{\ln 2}{k} = \frac{0.693}{k}$$

**16.8** Relating the rate constant to the temperature (Arrhenius equation) (716):

$$k = Ae^{-E_a/RT}$$

**16.9** Relating the heat of reaction to the forward and reverse activation energies (717):

$$\Delta H_{\text{rxn}} = E_{a(\text{fwd})} - E_{a(\text{rev})}$$

**16.10** Calculating the activation energy (rearranged form of Arrhenius equation) (718):

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$$

**16.11** Relating the rate of enzyme catalysis to substrate concentration (Michaelis-Menten equation) (734):

$$\text{Rate} = k_2 [\text{ES}] = \frac{k_2 [\text{E}]_0 [\text{S}]}{K_M + [\text{S}]}$$

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

**16.1A** (a)  $4\text{NO}(g) + \text{O}_2(g) \longrightarrow 2\text{N}_2\text{O}_3(g)$

$$\text{Rate} = -\frac{d[\text{O}_2]}{dt} = -\frac{1}{4} \frac{d[\text{NO}]}{dt} = \frac{1}{2} \frac{d[\text{N}_2\text{O}_3]}{dt}$$

$$\begin{aligned} \text{(b)} \quad -\frac{d[\text{O}_2]}{dt} &= -\frac{1}{4} \frac{d[\text{NO}]}{dt} = -\frac{1}{4} (-1.60 \times 10^{-4} \text{ mol/L}\cdot\text{s}) \\ &= 4.00 \times 10^{-5} \text{ mol/L}\cdot\text{s} \end{aligned}$$

**16.1B** (a) Since the changes in concentrations of  $\text{NH}_3$  and  $\text{O}_2$  are negative, those substances are the reactants:

$$\begin{aligned} \text{(b)} \quad -\frac{1}{5} \frac{d[\text{O}_2]}{dt} &= \frac{1}{6} \frac{d[\text{H}_2\text{O}]}{dt} \\ -\frac{d[\text{O}_2]}{dt} &= \frac{5}{6} \frac{d[\text{H}_2\text{O}]}{dt} = \frac{5}{6} (2.52 \times 10^{-2} \text{ mol/L}\cdot\text{s}) \\ &= 2.10 \times 10^{-2} \text{ mol/L}\cdot\text{s} \end{aligned}$$

**16.2A** (a) First order in  $\text{I}^-$ , first order in  $\text{BrO}_3^-$ , second order in  $\text{H}^+$ ; fourth order overall

(b)  $\text{Rate} = k[\text{I}^-][\text{BrO}_3^-][\text{H}^+]^2 = k(3)(3)(2)^2 = 36k$ ; the rate increases by a factor of 36.

**16.2B** (a) Second order in  $\text{ClO}_2$ , first order in  $\text{OH}^-$ ; third order overall

(b)  $\text{Rate} = k[\text{ClO}_2]^2[\text{OH}^-] = k(0.5)^2(2) = 0.5$ ; the rate decreases by a factor of  $\frac{1}{2}$ .

**16.3A**  $\text{Rate} = k[\text{H}_2]^m[\text{I}_2]^n$ . From Experiments 1 and 3:

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{k[\text{H}_2]_3^m [\text{I}_2]_3^n}{k[\text{H}_2]_1^m [\text{I}_2]_1^n} = \left( \frac{[\text{H}_2]_3}{[\text{H}_2]_1} \right)^m$$

$$\text{or} \quad \frac{9.3 \times 10^{-23} \text{ mol/L}\cdot\text{s}}{1.9 \times 10^{-23} \text{ mol/L}\cdot\text{s}} = \left( \frac{0.0550 \text{ mol/L}}{0.0113 \text{ mol/L}} \right)^m$$

This gives  $4.9 = (4.9)^m$ , so  $m = 1$ . From Experiments 2 and 4:

$$\frac{\text{Rate 4}}{\text{Rate 2}} = \frac{k[\text{H}_2]_4^m [\text{I}_2]_4^n}{k[\text{H}_2]_2^m [\text{I}_2]_2^n} = \left( \frac{[\text{I}_2]_4}{[\text{I}_2]_2} \right)^n$$

$$\text{or} \quad \frac{1.9 \times 10^{-22} \text{ mol/L}\cdot\text{s}}{1.1 \times 10^{-22} \text{ mol/L}\cdot\text{s}} = \left( \frac{0.0056 \text{ mol/L}}{0.0033 \text{ mol/L}} \right)^n$$

This gives  $1.7 = (1.7)^n$ , so  $n = 1$ . Therefore,  $\text{rate} = k[\text{H}_2][\text{I}_2]$ ; second order overall. From Experiment 1:

$$\begin{aligned} k &= \frac{\text{rate}}{[\text{H}_2][\text{I}_2]} = \frac{1.9 \times 10^{-23} \text{ mol/L}\cdot\text{s}}{(0.0113 \text{ mol/L})(0.0011 \text{ mol/L})} \\ &= 1.5 \times 10^{-18} \text{ L/mol}\cdot\text{s} \end{aligned}$$

The average value of  $k$  from all four experiments is  $1.5 \times 10^{-18} \text{ L/mol}\cdot\text{s}$ .

**16.3B** (a)  $\text{Rate} = k[\text{H}_2\text{SeO}_3]^m[\text{I}^-]^n[\text{H}^+]^p$ . From Experiments 1 and 3:

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \left( \frac{[\text{H}_2\text{SeO}_3]_3}{[\text{H}_2\text{SeO}_3]_1} \right)^m$$

$$\text{or} \quad \frac{3.94 \times 10^{-6} \text{ mol/L}\cdot\text{s}}{9.85 \times 10^{-7} \text{ mol/L}\cdot\text{s}} = \left( \frac{1.0 \times 10^{-2} \text{ mol/L}}{2.5 \times 10^{-3} \text{ mol/L}} \right)^m$$

This gives  $4 = (4)^m$ , so  $m = 1$ . From Experiments 1 and 2:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \left( \frac{[\text{I}^-]_2}{[\text{I}^-]_1} \right)^n$$

$$\text{or} \quad \frac{7.88 \times 10^{-6} \text{ mol/L}\cdot\text{s}}{9.85 \times 10^{-7} \text{ mol/L}\cdot\text{s}} = \left( \frac{3.0 \times 10^{-2} \text{ mol/L}}{1.5 \times 10^{-2} \text{ mol/L}} \right)^n$$

This gives  $8 = (2)^n$ , so  $n = 3$ . From Experiments 2 and 4:

$$\frac{\text{Rate 4}}{\text{Rate 2}} = \left( \frac{[\text{H}^+]_4}{[\text{H}^+]_2} \right)^p$$

$$\text{or} \quad \frac{3.15 \times 10^{-5} \text{ mol/L}\cdot\text{s}}{7.88 \times 10^{-6} \text{ mol/L}\cdot\text{s}} = \left( \frac{3.0 \times 10^{-2} \text{ mol/L}}{1.5 \times 10^{-2} \text{ mol/L}} \right)^p$$

This gives  $4 = (2)^p$ , so  $p = 2$ . Therefore,  $\text{rate} = k[\text{H}_2\text{SeO}_3][\text{I}^-]^3[\text{H}^+]^2$ .

(b) From Experiment 1:

$$\begin{aligned} k &= \frac{\text{rate}}{[\text{H}_2\text{SeO}_3][\text{I}^-]^3[\text{H}^+]^2} \\ &= \frac{9.85 \times 10^{-7} \text{ mol/L}\cdot\text{s}}{(2.5 \times 10^{-3} \text{ mol/L})(1.5 \times 10^{-2} \text{ mol/L})^3(1.5 \times 10^{-2} \text{ mol/L})^2} \\ &= 5.2 \times 10^5 \text{ L}^5/\text{mol}^5\cdot\text{s} \end{aligned}$$

**16.4A** (a) The rate law shows the reaction is zero order in Y, so the rate is not affected by doubling Y. The reaction is second order in X; since the amount of X does not change, the rate does not change either:  $\text{rate of Expt 2} = \text{rate of Expt 1} = 0.25 \times 10^{-5} \text{ mol/L}\cdot\text{s}$

(b) The rate of Expt 3 is four times that of Expt 1, so  $[\text{X}]$  doubles.

**16.4B** (a) The rate law is  $\text{rate} = k[\text{A}]^m[\text{B}]^n$ . For reactant B in Expts 1 and 2:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{k[\text{A}]_2^m [\text{B}]_2^n}{k[\text{A}]_1^m [\text{B}]_1^n} = \left( \frac{[\text{B}]_2}{[\text{B}]_1} \right)^n$$

$$\text{or} \quad \frac{1.6 \times 10^{-3} \text{ mol/L}\cdot\text{s}}{1.6 \times 10^{-3} \text{ mol/L}\cdot\text{s}} = \left( \frac{2 \text{ particles}}{4 \text{ particles}} \right)^n$$

Thus,  $1 = (0.5)^n$  so  $n = 0$ . For reactant A in Expts 1 and 3:

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{k[\text{A}]_3^m [\text{B}]_3^n}{k[\text{A}]_1^m [\text{B}]_1^n} = \left( \frac{[\text{A}]_3}{[\text{A}]_1} \right)^m$$

$$\text{or} \quad \frac{8.0 \times 10^{-4} \text{ mol/L}\cdot\text{s}}{1.6 \times 10^{-3} \text{ mol/L}\cdot\text{s}} = \left( \frac{2 \text{ particles}}{4 \text{ particles}} \right)^m$$

Thus,  $0.5 = (0.5)^m$  so  $m = 1$ . Therefore,  $\text{rate} = k[\text{A}][\text{B}]^0$  or  $\text{rate} = k[\text{A}]$ .

(b) The rate for Expt 4 is twice as great as the rate for Expt 1; since  $[\text{A}]$  has a reaction order of 1, twice as many A particles should appear in the scene for Expt 4:  $2 \times 4 \text{ particles} = 8 \text{ particles}$ .

**16.5A** The reaction is second order in HI.

$$\frac{1}{[\text{A}]_t} - \frac{1}{[\text{A}]_0} = kt$$

$$\frac{1}{0.00900 \text{ mol/L}} - \frac{1}{0.0100 \text{ mol/L}} = (2.4 \times 10^{-21} \text{ L/mol}\cdot\text{s})(t)$$

$$t = 4.6 \times 10^{21} \text{ s (or } 1.5 \times 10^{14} \text{ yr)}$$

$$16.5B \text{ (a)} \quad \ln \frac{[\text{H}_2\text{O}_2]_0}{[\text{H}_2\text{O}_2]_t} = kt$$

$$\ln \frac{1.28 \text{ mol/L}}{0.85 \text{ mol/L}} = k(10.0 \text{ min})$$

$$k = 0.041/\text{min}$$

(b) If 25% of the  $\text{H}_2\text{O}_2$  decomposes, 75% remains. Assuming an initial concentration of 1.0 M means that the concentration is 0.75 M at time  $t$ :

$$\ln \frac{[\text{H}_2\text{O}_2]_0}{[\text{H}_2\text{O}_2]_t} = kt$$

$$\ln \frac{1.0 \text{ mol/L}}{0.75 \text{ mol/L}} = (0.041/\text{min})(t)$$

$$t = 7.0 \text{ min}$$

16.6A (a) After 2.5 min, the number of particles of X has decreased from 12 to 6, so  $t_{1/2} = 2.5 \text{ min}$ . At 5.0 min, which is two half-lives, 3 particles of X will remain and an additional 3 particles of Y will be formed, for a total of 9 particles of Y.

(b) At 10.0 min (four half-lives), there are 0.75 particles of X ( $12 \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2}$ ).

$$\text{Amount (mol)} = 0.75 \text{ particles} \times \frac{0.20 \text{ mol X}}{1 \text{ particle}} = 0.15 \text{ mol X}$$

$$M = \frac{0.15 \text{ mol X}}{0.50 \text{ L}} = 0.30 \text{ M}$$

16.6B (a) The half-life is 24 min; the third scene represents four half-lives (1 particle is  $\frac{1}{16}$  of the initial amount;  $\frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} = \frac{1}{16}$ ). Four half-lives is  $4 \times 24 \text{ min} = 96 \text{ min}$ .

(b) At 72 min (three half-lives), there are 2 particles of A.

$$\text{Amount (mol)} = 2 \text{ particles} \times \frac{0.10 \text{ mol A}}{1 \text{ particle}} = 0.20 \text{ mol A}$$

$$M = \frac{0.20 \text{ mol A}}{0.25 \text{ L}} = 0.80 \text{ M}$$

$$16.7A \quad k = \frac{\ln 2}{t_{1/2}} = \frac{0.693}{13.1 \text{ h}} = 5.29 \times 10^{-2} \text{ h}^{-1}$$

$$16.7B \text{ (a)} \quad t_{1/2} = \frac{\ln 2}{k} = \frac{0.693}{9 \times 10^{-2} \text{ day}^{-1}} = 8 \text{ days}$$

(b) 40 days is five half-lives;  $\frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} = (\frac{1}{2})^5 = \frac{1}{32}$  remains in the environment.

$$16.8A \quad \ln \frac{k_2}{k_1} = \frac{E_a}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$$

$$\ln \frac{0.286 \text{ L/mol}\cdot\text{s}}{k_1} = \frac{1.00 \times 10^5 \text{ J/mol}}{8.314 \text{ J/mol}\cdot\text{K}} \times \left( \frac{1}{490. \text{ K}} - \frac{1}{500. \text{ K}} \right) = 0.491$$

$$\frac{0.286 \text{ L/mol}\cdot\text{s}}{k_1} = e^{0.491} = 1.63$$

$$k_1 = 0.175 \text{ L/mol}\cdot\text{s}$$

16.8B If the reaction rate is twice as fast,  $k_2 = k_1 \times 2 = 7.02 \times 10^{-3} \text{ L/mol}\cdot\text{s} \times 2 = 1.40 \times 10^{-2} \text{ L/mol}\cdot\text{s}$ .

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$$

$$\ln \frac{1.40 \times 10^{-2} \text{ L/mol}\cdot\text{s}}{7.02 \times 10^{-3} \text{ L/mol}\cdot\text{s}} = \frac{1.14 \times 10^5 \text{ J/mol}}{8.314 \text{ J/mol}\cdot\text{K}} \times \left( \frac{1}{500. \text{ K}} - \frac{1}{T_2} \right)$$

$$0.69029 = 13712 \text{ K} \times \left( 0.00200 \text{ K}^{-1} - \frac{1}{T_2} \right)$$

$$5.0342 \times 10^{-5} \text{ K}^{-1} = \left( 0.00200 \text{ K}^{-1} - \frac{1}{T_2} \right)$$

$$0.00195 \text{ K}^{-1} = \frac{1}{T_2}$$

$$T_2 = 513 \text{ K}$$

$$16.9A \quad E_{a(\text{rev})} = E_{a(\text{fwd})} - \Delta H_{\text{rxn}} = 78 \text{ kJ} - 72 \text{ kJ} = 6 \text{ kJ}$$

$$16.9B \quad \Delta H_{\text{rxn}} = E_{a(\text{fwd})} - E_{a(\text{rev})} = 7 \text{ kJ} - 72 \text{ kJ} = -65 \text{ kJ}$$

16.10A (a) Balanced equation:  $2\text{H}_2\text{O}_2(\text{aq}) \longrightarrow 2\text{H}_2\text{O}(\text{l}) + \text{O}_2(\text{g})$

(b) Step 1 is unimolecular; steps 2 and 3 are bimolecular.

(c)  $\text{Rate}_1 = k_1[\text{H}_2\text{O}_2]$ ;  $\text{Rate}_2 = k_2[\text{H}_2\text{O}_2][\text{OH}]$ ;  $\text{Rate}_3 = k_3[\text{HO}_2][\text{OH}]$

16.10B (a) Balanced equation:

(b) All steps are bimolecular.

(c)  $\text{Rate}_1 = k_1[\text{NO}]^2$ ;  $\text{Rate}_2 = k_2[\text{N}_2\text{O}_2][\text{H}_2]$ ;  $\text{Rate}_3 = k_3[\text{N}_2\text{O}][\text{H}_2]$

16.11A (a) The intermediates are OH and  $\text{HO}_2$ .

(b) The reaction is first order in  $\text{H}_2\text{O}_2$ ; step 1 must be the rate-determining step.

16.11B (a) The intermediates are  $\text{N}_2\text{O}_2$  and  $\text{N}_2\text{O}$ .

(b) From step 2,  $\text{rate} = k_2[\text{N}_2\text{O}_2][\text{H}_2]$ ; from step 1,

$$k_1[\text{NO}]^2 = k_{-1}[\text{N}_2\text{O}_2] \text{ or } [\text{N}_2\text{O}_2] = \frac{k_1}{k_{-1}}[\text{NO}]^2. \text{ Substituting into the rate law from step 2 gives}$$

$$\text{rate} = k_2[\text{N}_2\text{O}_2][\text{H}_2] = k_2 \frac{k_1}{k_{-1}}[\text{NO}]^2[\text{H}_2], \text{ or rate} = k[\text{NO}]^2[\text{H}_2].$$

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

### Focusing on Reaction Rate

#### Concept Review Questions

**16.1** What variable of a chemical reaction is measured over time to obtain the reaction rate?

**16.2** How does an increase in pressure affect the rate of a gas-phase reaction? Explain.

**16.3** A reaction is carried out with water as the solvent. How does the addition of more water to the reaction vessel affect the rate of the reaction? Explain.

**16.4** A gas reacts with a solid that is present in large chunks. Then the reaction is run again with the solid pulverized. How does the increase in the surface area of the solid affect the rate of its reaction with the gas? Explain.

**16.5** How does an increase in temperature affect the rate of a reaction? Explain the two factors involved.

**16.6** In a kinetics experiment, a chemist places crystals of iodine in a closed reaction vessel, introduces a given quantity of  $\text{H}_2$  gas, and obtains data to calculate the rate of HI formation. In a second experiment, she uses the same amounts of iodine and hydrogen, but first warms the flask to  $130^\circ\text{C}$ , a temperature above the sublimation point of iodine. In which of these experiments does the reaction proceed at a higher rate? Explain.

### Expressing the Reaction Rate

(Sample Problem 16.1)

#### Concept Review Questions

**16.7** Define *reaction rate*. Assuming constant temperature and a closed reaction vessel, why does the rate change with time?

**16.8** (a) What is the difference between an average rate and an instantaneous rate? (b) What is the difference between an initial rate and an instantaneous rate?

**16.9** Give two reasons to measure initial rates in a kinetics study.

**16.10** For the reaction  $\text{A}(g) \rightarrow \text{B}(g)$ , sketch two curves on the same set of axes that show

- (a) The formation of product as a function of time  
(b) The consumption of reactant as a function of time

**16.11** For the reaction  $\text{C}(g) \rightarrow \text{D}(g)$ ,  $[\text{C}]$  vs. time is plotted:

How do you determine each of the following?

- (a) The average rate over the entire experiment  
(b) The reaction rate at time  $x$   
(c) The initial reaction rate  
(d) Would the values in parts (a), (b), and (c) be different if you plotted  $[\text{D}]$  vs. time? Explain.

### Skill-Building Exercises (grouped in similar pairs)

**16.12** The compound  $\text{AX}_2$  decomposes according to the equation  $2\text{AX}_2(g) \rightarrow 2\text{AX}(g) + \text{X}_2(g)$ . In one experiment,  $[\text{AX}_2]$  was measured at various times and these data were obtained:

Time (s)	$[\text{AX}_2]$ (mol/L)
0.0	0.0500
2.0	0.0448
6.0	0.0300
8.0	0.0249
10.0	0.0209
20.0	0.0088

- (a) Find the average rate over the entire experiment.  
(b) Is the initial rate higher or lower than the rate in part (a)? Use graphical methods to estimate the initial rate.

**16.13** (a) Use the data from Problem 16.12 to calculate the average rate from 8.0 to 20.0 s.

- (b) Is the rate at exactly 5.0 s higher or lower than the rate in part (a)? Use graphical methods to estimate the rate at 5.0 s.

**16.14** Express the rate of this reaction in terms of the change in concentration of each of the reactants and products:

When  $[\text{C}]$  is increasing at  $2 \text{ mol/L}\cdot\text{s}$ , how fast is  $[\text{A}]$  decreasing?

**16.15** Express the rate of this reaction in terms of the change in concentration of each of the reactants and products:

When  $[\text{E}]$  is increasing at  $0.25 \text{ mol/L}\cdot\text{s}$ , how fast is  $[\text{F}]$  increasing?

**16.16** Express the rate of this reaction in terms of the change in concentration of each of the reactants and products:

When  $[\text{B}]$  is decreasing at  $0.5 \text{ mol/L}\cdot\text{s}$ , how fast is  $[\text{A}]$  decreasing?

**16.17** Express the rate of this reaction in terms of the change in concentration of each of the reactants and products:

When  $[\text{D}]$  is decreasing at  $0.1 \text{ mol/L}\cdot\text{s}$ , how fast is  $[\text{H}]$  increasing?

**16.18** Reaction rate is expressed in terms of changes in concentration of reactants and products. Write a balanced equation for the reaction with this rate expression:

$$\text{Rate} = -\frac{1}{2} \frac{d[\text{N}_2\text{O}_5]}{dt} = \frac{1}{4} \frac{d[\text{NO}_2]}{dt} = \frac{d[\text{O}_2]}{dt}$$

**16.19** Reaction rate is expressed in terms of changes in concentration of reactants and products. Write a balanced equation for the reaction with this rate expression:

$$\text{Rate} = -\frac{d[\text{CH}_4]}{dt} = -\frac{1}{2} \frac{d[\text{O}_2]}{dt} = \frac{1}{2} \frac{d[\text{H}_2\text{O}]}{dt} = \frac{d[\text{CO}_2]}{dt}$$

### Problems in Context

**16.20** The decomposition of NOBr is studied manometrically because the number of moles of gas changes; it cannot be studied colorimetrically because both NOBr and Br<sub>2</sub> are reddish brown:

Use the data below to answer the following:

- Determine the average rate over the entire experiment.
- Determine the average rate between 2.00 and 4.00 s.
- Use graphical methods to estimate the initial reaction rate.
- Use graphical methods to estimate the rate at 7.00 s.
- At what time does the instantaneous rate equal the average rate over the entire experiment?

Time (s)	[NOBr] (mol/L)
0.00	0.0100
2.00	0.0071
4.00	0.0055
6.00	0.0045
8.00	0.0038
10.00	0.0033

**16.21** The formation of ammonia is one of the most important processes in the chemical industry:

Express the rate in terms of changes in [N<sub>2</sub>], [H<sub>2</sub>], and [NH<sub>3</sub>].

**16.22** Although the depletion of stratospheric ozone threatens life on Earth today, its accumulation was one of the crucial processes that allowed life to develop in prehistoric times:

- Express the reaction rate in terms of [O<sub>2</sub>] and [O<sub>3</sub>].
- At a given instant, the reaction rate in terms of [O<sub>2</sub>] is 2.17 × 10<sup>-5</sup> mol/L·s. What is it in terms of [O<sub>3</sub>]?

### The Rate Law and Its Components

(Sample Problems 16.2 to 16.4)

#### Concept Review Questions

**16.23** The rate law for the general reaction

is rate =  $k[\text{A}]^m[\text{B}]^n \cdots$ . (a) Explain the meaning of  $k$ . (b) Explain the meanings of  $m$  and  $n$ . Does  $m = a$  and  $n = b$ ? Explain. (c) If the reaction is first order in A and second order in B, and time is measured in minutes (min), what are the units for  $k$ ?

**16.24** You are studying the reaction

to determine its rate law. Assuming that you have a valid experimental procedure for obtaining [A<sub>2</sub>] and [B<sub>2</sub>] at various times, explain how you determine (a) the initial rate, (b) the reaction orders, and (c) the rate constant.

**16.25** By what factor does the rate change in each of the following cases (assuming constant temperature)?

- A reaction is first order in reactant A, and [A] is doubled.
- A reaction is second order in reactant B, and [B] is halved.
- A reaction is second order in reactant C, and [C] is tripled.

### Skill-Building Exercises (grouped in similar pairs)

**16.26** Give the individual reaction orders for all substances and the overall reaction order from the following rate law:

$$\text{Rate} = k[\text{BrO}_3^-][\text{Br}^-][\text{H}^+]^2$$

**16.27** Give the individual reaction orders for all substances and the overall reaction order from the following rate law:

$$\text{Rate} = k \frac{[\text{O}_3]^2}{[\text{O}_2]}$$

**16.28** By what factor does the rate in Problem 16.26 change if each of the following changes occurs: (a) [BrO<sub>3</sub><sup>-</sup>] is doubled; (b) [Br<sup>-</sup>] is halved; (c) [H<sup>+</sup>] is quadrupled?

**16.29** By what factor does the rate in Problem 16.27 change if each of the following changes occurs: (a) [O<sub>3</sub>] is doubled; (b) [O<sub>2</sub>] is doubled; (c) [O<sub>2</sub>] is halved?

**16.30** Give the individual reaction orders for all substances and the overall reaction order from this rate law:

$$\text{Rate} = k[\text{NO}_2]^2[\text{Cl}_2]$$

**16.31** Give the individual reaction orders for all substances and the overall reaction order from this rate law:

$$\text{Rate} = k \frac{[\text{HNO}_2]^4}{[\text{NO}]^2}$$

**16.32** By what factor does the rate in Problem 16.30 change if each of the following changes occurs: (a) [NO<sub>2</sub>] is tripled; (b) [NO<sub>2</sub>] and [Cl<sub>2</sub>] are doubled; (c) [Cl<sub>2</sub>] is halved?

**16.33** By what factor does the rate in Problem 16.31 change if each of the following changes occurs: (a) [HNO<sub>2</sub>] is doubled; (b) [NO] is doubled; (c) [HNO<sub>2</sub>] is halved?

**16.34** For the reaction

the following data were obtained at constant temperature:

Experiment	Initial Rate (mol/L·min)	Initial [A] (mol/L)	Initial [B] (mol/L)
1	5.00	0.100	0.100
2	45.0	0.300	0.100
3	10.0	0.100	0.200
4	90.0	0.300	0.200

(a) What is the order with respect to each reactant? (b) Write the rate law. (c) Calculate  $k$  (using the data from Expt 1).

**16.35** For the reaction

the following data were obtained at constant temperature:

Expt	Initial Rate (mol/L·s)	Initial [A] (mol/L)	Initial [B] (mol/L)	Initial [C] (mol/L)
1	6.25 × 10 <sup>-3</sup>	0.0500	0.0500	0.0100
2	1.25 × 10 <sup>-2</sup>	0.1000	0.0500	0.0100
3	5.00 × 10 <sup>-2</sup>	0.1000	0.1000	0.0100
4	6.25 × 10 <sup>-3</sup>	0.0500	0.0500	0.0200

(a) What is the order with respect to each reactant? (b) Write the rate law. (c) Calculate  $k$  (using the data from Expt 1).

**16.36** Without consulting Table 16.3, give the units of the rate constants for reactions with the following overall orders: (a) first order; (b) second order; (c) third order; (d)  $\frac{5}{2}$  order.

**16.37** Give the overall reaction order that corresponds to a rate constant with each of the following units: (a)  $\text{mol/L}\cdot\text{s}$ ; (b)  $\text{yr}^{-1}$ ; (c)  $(\text{mol/L})^{1/2}\cdot\text{s}^{-1}$ ; (d)  $(\text{mol/L})^{-5/2}\cdot\text{min}^{-1}$ .

### Problems in Context

**16.38** Phosgene is a toxic gas prepared by the reaction of carbon monoxide with chlorine:

These data were obtained in a kinetics study of its formation:

Experiment	Initial Rate (mol/L·s)	Initial [CO] (mol/L)	Initial [Cl <sub>2</sub> ] (mol/L)
1	$1.29 \times 10^{-29}$	1.00	0.100
2	$1.33 \times 10^{-30}$	0.100	0.100
3	$1.30 \times 10^{-29}$	0.100	1.00
4	$1.32 \times 10^{-31}$	0.100	0.0100

- (a) Write the rate law for the formation of phosgene.  
 (b) Calculate the average value of the rate constant.

### Integrated Rate Laws: Concentration Changes over Time

(Sample Problems 16.5 to 16.7)

### Concept Review Questions

**16.39** How are integrated rate laws used to determine reaction order? What is the reaction order in each of these cases?

- (a) A plot of the natural logarithm of [reactant] vs. time is linear.  
 (b) A plot of the inverse of [reactant] vs. time is linear.  
 (c) [reactant] vs. time is linear.

**16.40** Define the *half-life* of a reaction. Explain on the molecular level why the half-life of a first-order reaction is constant.

### Skill-Building Exercises (grouped in similar pairs)

**16.41** For the simple decomposition reaction

rate =  $k[\text{AB}]^2$  and  $k = 0.2 \text{ L/mol}\cdot\text{s}$ . How long will it take for [AB] to reach one-third of its initial concentration of  $1.50 \text{ M}$ ?

**16.42** For the reaction in Problem 16.41, what is [AB] after 10.0 s?

**16.43** The first-order rate constant for the reaction  $\text{A}(\text{green}) \rightarrow \text{B}(\text{yellow})$  is  $0.063 \text{ min}^{-1}$ . The scenes below represent the reaction mixture at two different times:

What is the time at which the second scene occurs?

**16.44** The molecular scenes below represent the first-order reaction in which cyclopropane (*red*) is converted to propene (*green*):

Determine (a) the half-life and (b) the rate constant.

**16.45** In a first-order decomposition reaction, 50.0% of a compound decomposes in 10.5 min. (a) What is the rate constant of the reaction? (b) How long does it take for 75.0% of the compound to decompose?

**16.46** A decomposition reaction has a rate constant of  $0.0012 \text{ yr}^{-1}$ . (a) What is the half-life of the reaction? (b) How long does it take for [reactant] to reach 12.5% of its original value?

### Problems in Context

**16.47** In a study of ammonia production, an industrial chemist discovers that the compound decomposes to its elements  $\text{N}_2$  and  $\text{H}_2$  in a first-order process. She collects the following data:

Time (s)	0	1.000	2.000
[NH <sub>3</sub> ](mol/L)	4.000	3.986	3.974

- (a) Use graphical methods to determine the rate constant.  
 (b) What is the half-life for ammonia decomposition?

### Theories of Chemical Kinetics

(Sample Problems 16.8 and 16.9)

### Concept Review Questions

**16.48** What is the central idea of collision theory? How does this model explain the effect of concentration on reaction rate?

**16.49** Is collision frequency the only factor affecting rate? Explain.

**16.50** Arrhenius proposed that each reaction has an energy threshold that must be reached for the particles to react. The kinetic theory of gases proposes that the average kinetic energy of the particles is proportional to the absolute temperature. How do these concepts relate to the effect of temperature on rate?

**16.51** Use the exponential term in the Arrhenius equation to explain how temperature affects reaction rate.

**16.52** How is the activation energy determined from the Arrhenius equation?

**16.53** (a) Graph the relationship between  $k$  (vertical axis) and  $T$  (horizontal axis). (b) Graph the relationship between  $\ln k$  (vertical axis) and  $1/T$  (horizontal axis). How is the activation energy determined from this graph?

**16.54** (a) For a reaction with a given  $E_a$ , how does an increase in  $T$  affect the rate? (b) For a reaction at a given  $T$ , how does a decrease in  $E_a$  affect the rate?

**16.55** In the reaction  $AB + CD \rightleftharpoons EF$ ,  $4 \times 10^{-5}$  mol of AB molecules collide with  $4 \times 10^{-5}$  mol of CD molecules. Will  $4 \times 10^{-5}$  mol of EF form? Explain.

**16.56** Assuming the activation energies are equal, which of the following reactions will proceed at a higher rate at  $50^\circ\text{C}$ ? Explain.

### Skill-Building Exercises (grouped in similar pairs)

**16.57** For the reaction  $A(\text{g}) + B(\text{g}) \longrightarrow AB(\text{g})$ , how many unique collisions between A and B are possible if there are four particles of A and three particles of B present in the vessel?

**16.58** For the reaction  $A(\text{g}) + B(\text{g}) \longrightarrow AB(\text{g})$ , how many unique collisions between A and B are possible if 1.01 mol of A(g) and 2.12 mol of B(g) are present in the vessel?

**16.59** At  $25^\circ\text{C}$ , what is the fraction of collisions with energy equal to or greater than an activation energy of 100. kJ/mol?

**16.60** If the temperature in Problem 16.59 is increased to  $50^\circ\text{C}$ , by what factor does the fraction of collisions with energy equal to or greater than the activation energy change?

**16.61** The rate constant of a reaction is  $4.7 \times 10^{-3} \text{ s}^{-1}$  at  $25^\circ\text{C}$ , and the activation energy is 33.6 kJ/mol. What is  $k$  at  $75^\circ\text{C}$ ?

**16.62** The rate constant of a reaction is  $4.50 \times 10^{-5} \text{ L/mol}\cdot\text{s}$  at  $195^\circ\text{C}$  and  $3.20 \times 10^{-3} \text{ L/mol}\cdot\text{s}$  at  $258^\circ\text{C}$ . What is the activation energy of the reaction?

**16.63** For the reaction  $ABC + D \rightleftharpoons AB + CD$ ,  $\Delta H_{\text{rxn}}^\circ = -55 \text{ kJ/mol}$  and  $E_{\text{a}(\text{fwd})} = 215 \text{ kJ/mol}$ . Assuming a one-step reaction, (a) draw a reaction energy diagram; (b) calculate  $E_{\text{a}(\text{rev})}$ ; and (c) sketch a possible transition state if ABC is V shaped.

**16.64** For the reaction  $A_2 + B_2 \longrightarrow 2AB$ ,  $E_{\text{a}(\text{fwd})} = 125 \text{ kJ/mol}$  and  $E_{\text{a}(\text{rev})} = 85 \text{ kJ/mol}$ . Assuming the reaction occurs in one step, (a) draw a reaction energy diagram; (b) calculate  $\Delta H_{\text{rxn}}^\circ$ ; and (c) sketch a possible transition state.

### Problems in Context

**16.65** Understanding the high-temperature formation and breakdown of the nitrogen oxides is essential for controlling the pollutants generated from power plants and cars. The first-order breakdown of dinitrogen monoxide to its elements has rate constants of 0.76/s at  $727^\circ\text{C}$  and 0.87/s at  $757^\circ\text{C}$ . What is the activation energy of this reaction?

**16.66** Aqua regia, a mixture of HCl and  $\text{HNO}_3$ , has been used since alchemical times to dissolve many metals, including gold. Its orange color is due to the presence of nitrosyl chloride. Consider this one-step reaction for the formation of this compound:

- (a) Draw a reaction energy diagram, given  $E_{\text{a}(\text{fwd})} = 86 \text{ kJ/mol}$ .  
 (b) Calculate  $E_{\text{a}(\text{rev})}$ .  
 (c) Sketch a possible transition state for the reaction. (Note: The atom sequence of nitrosyl chloride is Cl–N–O.)

### Reaction Mechanisms: The Steps from Reactant to Product (Sample Problems 16.10 and 16.11)

### Concept Review Questions

**16.67** Is the rate of an overall reaction lower, higher, or equal to the average rate of the individual steps? Explain.

**16.68** Explain why the coefficients of an elementary step equal the reaction orders of its rate law but those of an overall reaction do not.

**16.69** Is it possible for more than one mechanism to be consistent with the rate law of a given reaction? Explain.

**16.70** What is the difference between a reaction intermediate and a transition state?

**16.71** Why is a bimolecular step more reasonable physically than a termolecular step?

**16.72** If a slow step precedes a fast step in a two-step mechanism, do the substances in the fast step appear in the overall rate law? Explain.

**16.73** If a fast step precedes a slow step in a two-step mechanism, how is the fast step affected? How is this effect used to determine the validity of the mechanism?

### Skill-Building Exercises (grouped in similar pairs)

**16.74** The proposed mechanism for a reaction is

- (a) What is the overall equation?  
 (b) Identify the intermediate(s), if any.  
 (c) What are the molecularity and the rate law for each step?  
 (d) Is the mechanism consistent with the actual rate law:  $\text{Rate} = k[\text{A}][\text{B}][\text{C}]$ ?  
 (e) Is the following one-step mechanism equally valid?  
 $\text{A}(\text{g}) + \text{B}(\text{g}) + \text{C}(\text{g}) \longrightarrow \text{D}(\text{g})$

**16.75** Consider the following mechanism:

- (a) What is the overall equation?  
 (b) Identify the intermediate(s), if any.  
 (c) What are the molecularity and the rate law for each step?  
 (d) Is the mechanism consistent with the actual rate law:  $\text{Rate} = k[\text{ClO}^-][\text{I}^-]$ ?

### Problems in Context

**16.76** In a study of nitrosyl halides, a chemist proposes the following mechanism for the synthesis of nitrosyl bromide:

If the rate law is  $\text{rate} = k[\text{NO}]^2[\text{Br}_2]$ , is the proposed mechanism valid? If so, show that it satisfies the three criteria for validity.

**16.77** The rate law for  $2\text{NO}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2\text{NO}_2(\text{g})$  is  $\text{rate} = k[\text{NO}]^2[\text{O}_2]$ . In addition to the mechanism in the text (Section 16.6), the following ones have been proposed:

- (a) Which of these mechanisms is consistent with the rate law?  
 (b) Which of these mechanisms is most reasonable? Why?

### Catalysis: Speeding Up a Reaction

#### Concept Review Questions

- 16.78** Consider the reaction  $\text{N}_2\text{O}(g) \xrightarrow{\text{Au}} \text{N}_2(g) + \frac{1}{2}\text{O}_2(g)$   
 (a) Does the gold catalyst (Au, above the arrow) act as a homogeneous or a heterogeneous catalyst?  
 (b) On the same set of axes, sketch the reaction energy diagrams for the catalyzed and the uncatalyzed reaction.

**16.79** Does a catalyst increase reaction rate by the same means as a rise in temperature does? Explain.

**16.80** In a classroom demonstration, hydrogen gas and oxygen gas are mixed in a balloon. The mixture is stable under normal conditions, but if a spark is applied to it or some powdered metal is added, the mixture explodes. (a) Is the spark acting as a catalyst? Explain. (b) Is the metal acting as a catalyst? Explain.

**16.81** A principle of green chemistry is that the energy needs of industrial processes should have minimal environmental impact. How can the use of catalysts lead to “greener” technologies?

**16.82** Enzymes are remarkably efficient catalysts that can increase reaction rates by as many as 20 orders of magnitude.

- (a) How does an enzyme affect the transition state of a reaction, and how does this effect increase the reaction rate?  
 (b) What characteristics of enzymes give them this effectiveness as catalysts?

### Comprehensive Problems

**16.83** Experiments show that each of the following redox reactions is second order overall:

- (a) When  $[\text{NO}_2]$  in reaction 1 is doubled, the rate quadruples. Write the rate law for this reaction.  
 (b) When  $[\text{NO}]$  in reaction 2 is doubled, the rate doubles. Write the rate law for this reaction.  
 (c) In each reaction, the initial concentrations of the reactants are equal. For each reaction, what is the ratio of the initial rate to the rate when the reaction is 50% complete?  
 (d) In reaction 1, the initial  $[\text{NO}_2]$  is twice the initial  $[\text{CO}]$ . What is the ratio of the initial rate to the rate at 50% completion?  
 (e) In reaction 2, the initial  $[\text{NO}]$  is twice the initial  $[\text{O}_3]$ . What is the ratio of the initial rate to the rate at 50% completion?

**16.84** Consider the following reaction energy diagram:

- (a) How many elementary steps are in the reaction mechanism?  
 (b) Which step is rate-limiting?  
 (c) Is the overall reaction exothermic or endothermic?

**16.85** Reactions between certain haloalkanes (alkyl halides) and water produce alcohols. Consider the overall reaction for *t*-butyl bromide (2-bromo-2-methylpropane):

The experimental rate law is  $\text{rate} = k[(\text{CH}_3)_3\text{CBr}]$ . The accepted mechanism for the reaction is

- (a) Why doesn't  $\text{H}_2\text{O}$  appear in the rate law?  
 (b) Write rate laws for the elementary steps.  
 (c) What reaction intermediates appear in the mechanism?  
 (d) Show that the mechanism is consistent with the experimental rate law.

**16.86** Archaeologists can determine the age of an artifact made of wood or bone by measuring the amount of the radioactive isotope  $^{14}\text{C}$  present in the object. The amount of this isotope decreases in a first-order process. If 15.5% of the original amount of  $^{14}\text{C}$  is present in a wooden tool at the time of analysis, what is the age of the tool? The half-life of  $^{14}\text{C}$  is 5730 yr.

**16.87** A slightly bruised apple will rot extensively in about 4 days at room temperature ( $20^\circ\text{C}$ ). If it is kept in the refrigerator at  $0^\circ\text{C}$ , the same extent of rotting takes about 16 days. What is the activation energy for the rotting reaction?

**16.88** Benzoyl peroxide, the substance most widely used against acne, has a half-life of  $9.8 \times 10^3$  days when refrigerated. How long will it take to lose 5% of its potency (95% remaining)?

**16.89** The rate law for the reaction

is  $\text{rate} = k[\text{NO}_2]^2$ ; one possible mechanism is shown in Section 16.6.

(a) Draw a reaction energy diagram for that mechanism, given that  $\Delta H_{\text{overall}}^\circ = -226 \text{ kJ/mol}$ .

(b) Consider the following alternative mechanism:

Is the alternative mechanism consistent with the rate law? Is one mechanism more reasonable physically? Explain.

**16.90** Consider the following general reaction and data:

Expt	Initial Rate (mol/L·s)	Initial [A] (mol/L)	Initial [B] (mol/L)	Initial [C] (mol/L)
1	$6.0 \times 10^{-6}$	0.024	0.085	0.032
2	$9.6 \times 10^{-5}$	0.096	0.085	0.032
3	$1.5 \times 10^{-5}$	0.024	0.034	0.080
4	$1.5 \times 10^{-6}$	0.012	0.170	0.032

- (a) What is the reaction order with respect to each reactant?  
 (b) Calculate the rate constant.  
 (c) Write the rate law for this reaction.  
 (d) Express the rate in terms of changes in concentration with time for each of the components.

**16.91** In acidic solution, the breakdown of sucrose into glucose and fructose has this rate law:  $\text{rate} = k[\text{H}^+][\text{sucrose}]$ . The initial rate of

sucrose breakdown is measured in a solution that is  $0.01\text{ M H}^+$ ,  $1.0\text{ M}$  sucrose,  $0.1\text{ M}$  fructose, and  $0.1\text{ M}$  glucose. How does the rate change if

- [sucrose] is changed to  $2.5\text{ M}$ ?
- [sucrose], [fructose], and [glucose] are all changed to  $0.5\text{ M}$ ?
- $[\text{H}^+]$  is changed to  $0.0001\text{ M}$ ?
- [sucrose] and  $[\text{H}^+]$  are both changed to  $0.1\text{ M}$ ?

**16.92** The citric acid cycle is the central reaction sequence in the cellular metabolism of humans and many other organisms. One of the key steps is catalyzed by the enzyme isocitrate dehydrogenase and the oxidizing agent  $\text{NAD}^+$ . In yeast, the reaction is eleventh order:

$$\text{Rate} = k[\text{enzyme}] [\text{isocitrate}]^4 [\text{AMP}]^2 [\text{NAD}^+]^m [\text{Mg}^{2+}]^2$$

What is the order with respect to  $\text{NAD}^+$ ?

**16.93** The following molecular scenes represent starting mixtures I and II for the reaction of A (black) with B (orange):

Each sphere represents  $0.010\text{ mol}$ , and the volume is  $0.50\text{ L}$ . If the reaction is first order in A and first order in B and the initial rate for I is  $8.3 \times 10^{-4}\text{ mol/L}\cdot\text{min}$ , what is the initial rate for II?

**16.94** Experiment shows that the rate of formation of carbon tetrachloride from chloroform,

is first order in  $\text{CHCl}_3$ ,  $\frac{1}{2}$  order in  $\text{Cl}_2$ , and  $\frac{3}{2}$  order overall. Show that the following mechanism is consistent with the rate law:

- $\text{Cl}_2(g) \rightleftharpoons 2\text{Cl}(g)$  [fast]
- $\text{Cl}(g) + \text{CHCl}_3(g) \longrightarrow \text{HCl}(g) + \text{CCl}_3(g)$  [slow]
- $\text{CCl}_3(g) + \text{Cl}(g) \longrightarrow \text{CCl}_4(g)$  [fast]

**16.95** A biochemist studying the breakdown of the insecticide DDT finds that it decomposes by a first-order reaction with a half-life of 12 yr. How long does it take DDT in a soil sample to decrease from 275 ppb to 10. ppb (parts per billion by mass)?

**16.96** Insulin is a polypeptide hormone that is released into the blood from the pancreas and stimulates fat and muscle to take up glucose; the insulin is used up in a first-order process. In a certain patient, this process has a half-life of 3.5 min. To maintain an adequate blood concentration of insulin, it must be replenished in a time interval equal to  $1/k$ . How long is the time interval for this patient?

**16.97** For the reaction  $\text{A}(g) + \text{B}(g) \longrightarrow \text{AB}(g)$ , the rate is  $0.20\text{ mol/L}\cdot\text{s}$ , when  $[\text{A}]_0 = [\text{B}]_0 = 1.0\text{ mol/L}$ . If the reaction is first order in B and second order in A, what is the rate when  $[\text{A}]_0 = 2.0\text{ mol/L}$  and  $[\text{B}]_0 = 3.0\text{ mol/L}$ ?

**16.98** The acid-catalyzed hydrolysis of sucrose occurs by the following overall reaction, whose kinetic data are given below:

[Sucrose] (mol/L)	Time (h)
0.501	0.00
0.451	0.50
0.404	1.00
0.363	1.50
0.267	3.00

- Determine the rate constant and the half-life of the reaction.
- How long does it take to hydrolyze 75% of the sucrose?
- Some studies have shown that this reaction is actually second order overall but appears to follow pseudo-first-order kinetics. Suggest a reason for this apparent first-order behavior.

**16.99** At body temperature ( $37^\circ\text{C}$ ), the rate constant of an enzyme-catalyzed decomposition is  $2.3 \times 10^{14}$  times that of the uncatalyzed reaction. If the frequency factor,  $A$ , is the same for both processes, by how much does the enzyme lower the  $E_a$ ?

**16.100** Is each of these statements true? If not, explain why.

- At a given  $T$ , all molecules have the same kinetic energy.
- Halving the  $P$  for a gaseous reaction doubles the rate.
- A higher activation energy gives a lower reaction rate.
- A temperature rise of  $10^\circ\text{C}$  doubles the rate of any reaction.
- If reactant molecules collide with greater energy than the activation energy, they change into product molecules.
- The activation energy of a reaction depends on temperature.
- The rate of a reaction increases as the reaction proceeds.
- Activation energy depends on collision frequency.
- A catalyst increases the rate by increasing collision frequency.
- Exothermic reactions are faster than endothermic reactions.
- Temperature has no effect on the frequency factor ( $A$ ).
- The activation energy of a reaction is lowered by a catalyst.
- For most reactions,  $\Delta H_{\text{rxn}}$  is lowered by a catalyst.
- The orientation probability factor ( $p$ ) is near 1 for reactions between single atoms.
- The initial rate of a reaction is its maximum rate.
- A bimolecular reaction is generally twice as fast as a unimolecular reaction.
- The molecularity of an elementary reaction is proportional to the molecular complexity of the reactant(s).

**16.101** For the decomposition of gaseous dinitrogen pentoxide,

the rate constant is  $k = 2.8 \times 10^{-3}\text{ s}^{-1}$  at  $60^\circ\text{C}$ . The initial concentration of  $\text{N}_2\text{O}_5$  is  $1.58\text{ mol/L}$ . (a) What is  $[\text{N}_2\text{O}_5]$  after 5.00 min? (b) What fraction of the  $\text{N}_2\text{O}_5$  has decomposed after 5.00 min?

**16.102** Even when a mechanism is consistent with the rate law, later work may show it to be incorrect. For example, the reaction between hydrogen and iodine has this rate law: rate =  $k[\text{H}_2][\text{I}_2]$ . The long-accepted mechanism had a single bimolecular step; that is, the overall reaction was thought to be elementary:

In the 1960s, however, spectroscopic evidence showed the presence of free I atoms during the reaction. Kineticists have since proposed a three-step mechanism:

- $\text{I}_2(g) \rightleftharpoons 2\text{I}(g)$  [fast]
- $\text{H}_2(g) + \text{I}(g) \rightleftharpoons \text{H}_2\text{I}(g)$  [fast]
- $\text{H}_2\text{I}(g) + \text{I}(g) \longrightarrow 2\text{HI}(g)$  [slow]

Show that this mechanism is consistent with the rate law.

**16.103** Suggest an experimental method for measuring the change in concentration with time for each of the following reactions:

- (a)  $\text{CH}_3\text{CH}_2\text{Br}(l) + \text{H}_2\text{O}(l) \longrightarrow \text{CH}_3\text{CH}_2\text{OH}(l) + \text{HBr}(aq)$   
 (b)  $2\text{NO}(g) + \text{Cl}_2(g) \longrightarrow 2\text{NOCl}(g)$

**16.104** An atmospheric chemist fills a container with gaseous  $\text{N}_2\text{O}_5$  to a pressure of 125 kPa, and the gas decomposes to  $\text{NO}_2$  and  $\text{O}_2$ . What is the partial pressure of  $\text{NO}_2$ ,  $P_{\text{NO}_2}$  (in kPa), when the total pressure is 178 kPa?

**16.105** Many drugs decompose in blood by a first-order process.  
 (a) Two tablets of aspirin supply 0.60 g of the active compound. After 30 min, this compound reaches a maximum concentration of 2 mg/100 mL of blood. If the half-life for its breakdown is 90 min, what is its concentration (in mg/100 mL) 2.5 h after it reaches its maximum concentration?  
 (b) For the decomposition of an antibiotic in a person with a normal temperature (98.6°F),  $k = 3.1 \times 10^{-5} \text{ s}^{-1}$ ; for a person with a fever (temperature of 101.9°F),  $k = 3.9 \times 10^{-5} \text{ s}^{-1}$ . If the person with the fever must take another pill when  $\frac{2}{3}$  of the first pill has decomposed, how many hours should she wait to take a second pill? A third pill? (Assume that the pill is effective immediately.)  
 (c) Calculate  $E_a$  for decomposition of the antibiotic in part (b).

**16.106** While developing a catalytic process to make ethylene glycol from synthesis gas ( $\text{CO} + \text{H}_2$ ), a chemical engineer finds the rate to be fourth order with respect to gas pressure. The uncertainty in the pressure reading is 5%. When the catalyst is modified, the rate increases by 10%. If you were the company patent attorney, would you file for a patent on this catalyst modification? Explain.

**16.107** Iodide ion reacts with chloromethane to displace chloride ion in a common organic substitution reaction:

- (a) Draw a wedge-bond structure of chloroform, and indicate the most effective direction of  $\text{I}^-$  attack.  
 (b) The analogous reaction with 2-chlorobutane results in a major change in specific rotation as measured by polarimetry. Explain, showing a wedge-bond structure of the product.

(c) Under different conditions, 2-chlorobutane loses  $\text{Cl}^-$  in a rate-determining step to form a planar intermediate. This cationic species reacts with  $\text{HI}$  and then loses  $\text{H}^+$  to form a product that exhibits no optical activity. Explain, showing a wedge-bond structure.

**16.108** Assume that water boils at 100.0°C in Houston (near sea level), and at 90.0°C in Cripple Creek, Colorado (near 9500 ft). If it takes 4.8 min to cook an egg in Cripple Creek and 4.5 min in Houston, what is  $E_a$  for this process?

**16.109** Sulfonation of benzene has the following mechanism:

- (1)  $2\text{H}_2\text{SO}_4 \longrightarrow \text{H}_3\text{O}^+ + \text{HSO}_4^- + \text{SO}_3$  [fast]  
 (2)  $\text{SO}_3 + \text{C}_6\text{H}_6 \longrightarrow \text{H}(\text{C}_6\text{H}_5^+)\text{SO}_3^-$  [slow]  
 (3)  $\text{H}(\text{C}_6\text{H}_5^+)\text{SO}_3^- + \text{HSO}_4^- \longrightarrow \text{C}_6\text{H}_5\text{SO}_3^- + \text{H}_2\text{SO}_4$  [fast]  
 (4)  $\text{C}_6\text{H}_5\text{SO}_3^- + \text{H}_3\text{O}^+ \longrightarrow \text{C}_6\text{H}_5\text{SO}_3\text{H} + \text{H}_2\text{O}$  [fast]

(a) Write an overall equation for the reaction. (b) Write the overall rate law in terms of the initial rate of the reaction.

**16.110** In the lower troposphere, ozone is one of the components of photochemical smog. It is generated in air when nitrogen dioxide, formed by the oxidation of nitrogen monoxide from car exhaust, reacts by the following mechanism:

- (1)  $\text{NO}_2(g) \xrightarrow{h\nu} \text{NO}(g) + \text{O}(g)$   
 (2)  $\text{O}(g) + \text{O}_2(g) \xrightarrow{h\nu} \text{O}_3(g)$

Assuming the rate of formation of atomic oxygen in step 1 equals the rate of its consumption in step 2, use the data below to calculate (a) the concentration of atomic oxygen  $[\text{O}]$  and (b) the rate of ozone formation.

$$k_1 = 6.0 \times 10^{-3} \text{ s}^{-1} \quad [\text{NO}_2] = 4.0 \times 10^{-9} \text{ M}$$

$$k_2 = 1.0 \times 10^6 \text{ L/mol}\cdot\text{s} \quad [\text{O}_2] = 1.0 \times 10^{-2} \text{ M}$$

**16.111** Chlorine is commonly used to disinfect drinking water, and inactivation of pathogens by chlorine follows first-order kinetics. The following data are for *E. coli* inactivation:

Contact Time (min)	Percent (%) Inactivation
0.00	0.0
0.50	68.3
1.00	90.0
1.50	96.8
2.00	99.0
2.50	99.7
3.00	99.9

- (a) Determine the first-order inactivation constant,  $k$ .  
 [Hint: % inactivation =  $100 \times (1 - [\text{A}]/[\text{A}]_0)$ .]  
 (b) How much contact time is required for 95% inactivation?

**16.112** The overall equation and rate law for the gas-phase decomposition of dinitrogen pentoxide are

Which of the following can be considered valid mechanisms for the reaction?

- I One-step collision  
 II  $2\text{N}_2\text{O}_5(g) \longrightarrow 2\text{NO}_3(g) + 2\text{NO}_2(g)$  [slow]  
 $2\text{NO}_3(g) \longrightarrow 2\text{NO}_2(g) + 2\text{O}(g)$  [fast]  
 $2\text{O}(g) \longrightarrow \text{O}_2(g)$  [fast]  
 III  $\text{N}_2\text{O}_5(g) \rightleftharpoons \text{NO}_3(g) + \text{NO}_2(g)$  [fast]  
 $\text{NO}_2(g) + \text{N}_2\text{O}_5(g) \longrightarrow 3\text{NO}_2(g) + \text{O}(g)$  [slow]  
 $\text{NO}_3(g) + \text{O}(g) \longrightarrow \text{NO}_2(g) + \text{O}_2(g)$  [fast]

**16.113** Nitrification is a biological process for removing  $\text{NH}_3$  from wastewater as  $\text{NH}_4^+$ :

The first-order rate constant is given as

$$k_1 = 0.47e^{0.095(T - 15^\circ\text{C})}$$

where  $k_1$  is in  $\text{day}^{-1}$  and  $T$  is in  $^\circ\text{C}$ .

(a) If the initial concentration of  $\text{NH}_3$  is  $3.0 \text{ mol/m}^3$ , how long will it take to reduce the concentration to  $0.35 \text{ mol/m}^3$  in the spring ( $T = 20^\circ\text{C}$ )?

(b) In the winter ( $T = 10^\circ\text{C}$ )?

(c) Using your answer to part (a), what is the rate of  $\text{O}_2$  consumption?

**16.114** Carbon disulfide, a poisonous, flammable liquid, is an excellent solvent for phosphorus, sulfur, and some other non-metals. A kinetic study of its gaseous decomposition gave these data:

Experiment	Initial Rate (mol/L·s)	Initial $[\text{CS}_2]$ (mol/L)
1	$12.7 \times 10^{-7}$	0.100
2	$2.2 \times 10^{-7}$	0.080
3	$1.5 \times 10^{-7}$	0.055
4	$1.2 \times 10^{-7}$	0.044

(a) Write the rate law for the decomposition of  $\text{CS}_2$ .

(b) Calculate the average value of the rate constant.

**16.115** Like any catalyst, palladium, platinum, or nickel catalyzes both directions of a reaction: addition of hydrogen to (hydrogenation) and its elimination from (dehydrogenation) carbon double bonds.

(a) Which variable determines whether an alkene will be hydrogenated or dehydrogenated?

(b) Which reaction requires a higher temperature?

(c) How can all-*trans* fats arise during hydrogenation of fats that contain some double bonds with a *cis* orientation?

**16.116** In a *clock reaction*, a dramatic color change occurs at a time determined by concentration and temperature. Consider the iodine clock reaction, whose overall equation is

As  $\text{I}_2$  forms, it is immediately consumed by its reaction with a fixed amount of added  $\text{S}_2\text{O}_3^{2-}$ :

Once the  $\text{S}_2\text{O}_3^{2-}$  is consumed, the excess  $\text{I}_2$  forms a blue-black product with starch present in solution:

The rate of the reaction is also influenced by the total concentration of ions, so  $\text{KCl}$  and  $(\text{NH}_4)_2\text{SO}_4$  are added to maintain a constant value. Use the data below, obtained at  $23^\circ\text{C}$ , to determine:

(a) The average rate for each trial

(b) The order with respect to each reactant

(c) The rate constant

(d) The rate law for the overall reaction

	Expt 1	Expt 2	Expt 3
0.200 M KI (mL)	10.0	20.0	20.0
0.100 M $\text{Na}_2\text{S}_2\text{O}_8$ (mL)	20.0	20.0	10.0
0.0050 M $\text{Na}_2\text{S}_2\text{O}_3$ (mL)	10.0	10.0	10.0
0.200 M KCl (mL)	10.0	0.0	0.0
0.100 M $(\text{NH}_4)_2\text{SO}_4$ (mL)	0.0	0.0	10.0
Time to color (s)	29.0	14.5	14.5

**16.117** Heat transfer to and from a reaction flask is often a critical factor in controlling reaction rate. The heat transferred ( $q$ ) depends on a heat transfer coefficient ( $h$ ) for the flask material, the temperature difference ( $\Delta T$ ) across the flask wall, and the commonly “wetted” area ( $A$ ) of the flask and bath:  $q = hA\Delta T$ . When an exothermic reaction is run at a given  $T$ , there is a bath temperature at which the reaction can no longer be controlled, and the reaction “runs away” suddenly. A similar problem is often seen when a reaction is “scaled up” from, say, a half-filled small flask to a half-filled large flask. Explain these behaviors.

**16.118** The growth of *Pseudomonas* bacteria is modeled as a first-order process with  $k = 0.035 \text{ min}^{-1}$  at  $37^\circ\text{C}$ . The initial *Pseudomonas* population density is  $1.0 \times 10^3$  cells/L. (a) What is the population density after 2 h? (b) What is the time required for the population to go from  $1.0 \times 10^3$  to  $2.0 \times 10^3$  cells/L?

**16.119** Consider the following organic reaction, in which one halogen replaces another in a haloalkane:

In acetone, this particular reaction goes to completion because  $\text{KI}$  is soluble in acetone but  $\text{KBr}$  is not. In the mechanism,  $\text{I}^-$  approaches the carbon *opposite* to the  $\text{Br}$  (see Figure 16.20, with  $\text{I}^-$  instead of  $\text{OH}^-$ ). After  $\text{Br}^-$  has been replaced by  $\text{I}^-$  and precipitates as  $\text{KBr}$ , other  $\text{I}^-$  ions react with the ethyl iodide by the same mechanism.

(a) If we designate the carbon bonded to the halogen as C-1, what is the shape around C-1 and the hybridization of C-1 in ethyl iodide?

(b) In the transition state, one of the two lobes of the unhybridized  $2p$  orbital of C-1 overlaps a  $p$  orbital of  $\text{I}$ , while the other lobe overlaps a  $p$  orbital of  $\text{Br}$ . What is the shape around C-1 and the hybridization of this carbon in the transition state?

(c) The deuterated reactant,  $\text{CH}_3\text{CHDBr}$  (where  $\text{D}$  is deuterium,  $^2\text{H}$ ), has two optical isomers because C-1 is chiral. If the reaction is run with one of the isomers, the ethyl iodide is *not* optically active. Explain.

**16.120** Another radioisotope of iodine,  $^{131}\text{I}$ , is also used to study thyroid function (see Follow-up Problem 16.7A). A patient is given a sample that is  $1.7 \times 10^{-4} \text{ M } ^{131}\text{I}$ . If the half-life is 8.04 days, what fraction of the radioactivity remains after 30. days?

**16.121** The effect of substrate concentration on the first-order growth rate of a microbial population follows the Monod equation:

$$\mu = \frac{\mu_{\text{max}}S}{K_s + S}$$

where  $\mu$  is the first-order growth rate ( $\text{s}^{-1}$ ),  $\mu_{\text{max}}$  is the maximum growth rate ( $\text{s}^{-1}$ ),  $S$  is the substrate concentration ( $\text{kg/m}^3$ ), and  $K_s$

is the value of  $S$  that gives one-half of the maximum growth rate (in  $\text{kg}/\text{m}^3$ ). For  $\mu_{\text{max}} = 1.5 \times 10^{-4} \text{ s}^{-1}$  and  $K_s = 0.03 \text{ kg}/\text{m}^3$ :

- Plot  $\mu$  vs.  $S$  for  $S$  between 0.0 and 1.0  $\text{kg}/\text{m}^3$ .
- The initial population density is  $5.0 \times 10^3 \text{ cells}/\text{m}^3$ . What is the density after 1.0 h, if the initial  $S$  is 0.30  $\text{kg}/\text{m}^3$ ?
- What is it if the initial  $S$  is 0.70  $\text{kg}/\text{m}^3$ ?

**16.122** The scenes depict four initial reaction mixtures for the reaction of A (blue) and B (yellow), with and without a solid present (gray cubes). The initial rate,  $-d[A]/dt$  (in  $\text{mol}/\text{L}\cdot\text{s}$ ), is shown, with each sphere representing 0.010 mol and the container volume at 0.50 L.

- What is the rate law in the absence of a catalyst?
- What is the overall reaction order?
- Find the rate constant.
- Do the gray cubes have a catalytic effect? Explain.

**16.123** The mathematics of the first-order rate law can be applied to any situation in which a quantity decreases by a constant fraction per unit of time (or unit of any other variable).

- As light moves through a solution, its intensity decreases per unit distance traveled in the solution. Show that

$$\ln \left( \frac{\text{intensity of light leaving the solution}}{\text{intensity of light entering the solution}} \right) = -\text{fraction of light removed per unit of length} \times \text{distance traveled in solution}$$

- The value of your savings declines under conditions of constant inflation. Show that

$$\ln \left( \frac{\text{value remaining}}{\text{initial value}} \right) = -\text{fraction lost per unit of time} \times \text{savings time interval}$$

**16.124** Figure 16.25 shows key steps in the metal-catalyzed (M) hydrogenation of ethene:

Use the following symbols to write a mechanism that gives the overall equation:

$\text{H}_2(\text{ads})$	adsorbed hydrogen molecules
$\text{M}-\text{H}$	hydrogen atoms bonded to metal atoms
$\text{C}_2\text{H}_4(\text{ads})$	adsorbed ethene molecules
$\text{C}_2\text{H}_5(\text{ads})$	adsorbed ethyl radicals

**16.125** Human liver enzymes catalyze the degradation of ingested toxins. By what factor is the rate of a detoxification changed if an enzyme lowers the  $E_a$  by 5 kJ/mol at 37°C?

**16.126** Acetone is one of the most important solvents in organic chemistry, used to dissolve everything from fats and waxes to airplane glue and nail polish. At high temperatures, it decomposes in a first-order process to methane and ketene ( $\text{CH}_2=\text{C}=\text{O}$ ). At 600°C, the rate constant is  $8.7 \times 10^{-3} \text{ s}^{-1}$ .

- What is the half-life of the reaction?
- How long does it take for 40.% of a sample of acetone to decompose?
- How long does it take for 90.% of a sample of acetone to decompose?

**16.127** A (green), B (blue), and C (red) are structural isomers. The molecular filmstrip depicts them undergoing a chemical change as time proceeds.

- Write a mechanism for the reaction.
- What role does C play?

**16.128** The reaction  $\text{A} + \text{B} \longrightarrow \text{C}$  is first order in A, first order in B, and second order overall with a rate constant of  $0.0350 \text{ M}^{-1}\text{s}^{-1}$ . What is the concentration of C after 1.5 min if  $[\text{A}]_0 = 2.00 \text{ M}$  and  $[\text{B}]_0 = 1.00 \text{ M}$ ?

**16.129** The rate law for the reaction  $\text{HOCl} + \text{NH}_3 \longrightarrow \text{NH}_2\text{Cl} + \text{H}_2\text{O}$  is  $\text{rate} = k[\text{HOCl}][\text{NH}_3]$  with  $k = 5.1 \times 10^6 \text{ L}/\text{mol}\cdot\text{s}$  at 25°C. The reaction becomes pseudo-first-order in  $\text{NH}_3$  by using a large excess of HOCl. How long does it take for 30% of the  $\text{NH}_3$  to react if the initial concentration of HOCl is  $2 \times 10^{-3} \text{ M}$ ?

**16.130** In the lower atmosphere, one of the mechanisms proposed for the decomposition of ozone to produce oxygen,  $2\text{O}_3 \longrightarrow 3\text{O}_2$ , is

- $\text{O}_3 \rightleftharpoons \text{O}_2 + \text{O}$
- $\text{O} + \text{O}_3 \longrightarrow 2\text{O}_2$

- Use the steady-state approximation to write the rate law, assuming that step 2 is the rate-determining step.

(b) The experimentally determined rate law is  $\text{rate} = k \frac{[\text{O}_3]^2}{[\text{O}_2]}$ . How can the rate law derived in (a) be rewritten to explain the known rate law?

**16.131** Consider the following mechanism for the decomposition of  $\text{NO}_2\text{Cl}$  to  $\text{NO}_2$  and  $\text{Cl}_2$ :

- $\text{NO}_2\text{Cl} \rightleftharpoons \text{NO}_2 + \text{Cl}$
- $\text{NO}_2\text{Cl} + \text{Cl} \longrightarrow \text{NO}_2 + \text{Cl}_2$

- (a) Use the steady-state approximation to express the rate of  $\text{Cl}_2$  production.
- (b) How is the rate law simplified if step 1 is the rate-determining step?
- (c) How is the rate law simplified if step 2 is the rate-determining step?

**16.132** The rate equation for an enzyme-catalyzed reaction has the following constants:  $K_M = 3 \times 10^{-2} \text{ M}$  and  $k_2 = 4 \times 10^4 \text{ s}^{-1}$ .

- (a) Calculate the maximum rate when the enzyme concentration is  $3 \times 10^{-6} \text{ mol/L}$ .

- (b) What is the substrate concentration if the rate is 25% of that calculated in (a)?

**16.133** Urea,  $(\text{NH}_2)_2\text{CO}$ , is used as a fertilizer because many soil bacteria contain the enzyme urease, which catalyzes the hydrolysis of urea into carbon dioxide and ammonia. Under a specific set of conditions, the Michaelis constant,  $K_M$ , for urease is  $2 \times 10^{-3} \text{ M}$  and  $k_2 = 2.5 \times 10^4 \text{ s}^{-1}$ . (a) Calculate the initial rate when  $[\text{urea}] = 2.5 \times 10^{-5} \text{ M}$  and  $[\text{urease}] = 4.0 \times 10^{-6} \text{ M}$ . (b) What is the maximum rate of reaction?

## Concepts and Skills to Review Before You Study This Chapter

- › reversibility of reactions (Section 4.7)
- › dependence of rate on concentration (Sections 16.2 and 16.5)
- › equilibrium vapor pressure (Section 12.2)
- › rate laws for elementary reactions (Section 16.6)
- › equilibrium nature of a saturated solution (Section 13.4)
- › function of a catalyst (Section 16.7)

**J**ust as reactions vary greatly in their speed, they also vary greatly in their extent. Indeed, kinetics and equilibrium apply to different aspects of a reaction:

- Kinetics applies to the *speed* (or rate) of a reaction, the concentration of reactant that disappears (or of product that appears) per unit time.
- Equilibrium applies to the *extent* of a reaction, the concentrations of reactant and product present after an unlimited time, that is, when no further change is occurring.

As you'll see, at equilibrium, no further *net* change occurs because the forward and reverse reactions reach a *balance*. Like traffic going back and forth across a bridge or people going up and down an escalator, the change in one direction is balanced by the change in the other. A fast reaction may go almost completely, just partially, or only slightly toward products before this balance is reached. Consider acid dissociation in water. In 1 M HCl, virtually all the hydrogen chloride molecules are dissociated into ions, whereas fewer than 1% of the acetic acid molecules are dissociated in 1 M CH<sub>3</sub>COOH. Yet both reactions take less than a second. Similarly, some slow reactions yield a large amount of product, whereas others yield very little. After a few years, a steel water tank will start to rust, and it will do so completely given enough time. But, no matter how long you wait, the water inside the tank will not decompose to hydrogen and oxygen.

Knowing the extent of a given reaction is crucial. How much product—medicine, polymer, or fuel—can you obtain from a particular reaction mixture? How can you adjust conditions to obtain more? If a reaction is slow but eventually has a good yield, will a catalyst speed it up enough to make it useful?

**IN THIS CHAPTER . . .** We consider the principles of equilibrium in systems of gases and/or pure liquids and solids.

- › We examine the equilibrium state at the macroscopic and molecular levels and see that equilibrium occurs when the forward and reverse reaction rates are equal.
- › We contrast the reaction quotient,  $Q$ , which changes as the reaction proceeds, with the equilibrium constant,  $K$ , which applies to the reaction at equilibrium.
- › We express the equilibrium condition in terms of concentrations or pressures and see how the two expressions are related.
- › We compare values of  $Q$  and  $K$  to determine the direction in which a system must proceed to reach equilibrium.
- › We develop a systematic approach to solving a variety of equilibrium problems.
- › We explore Le Châtelier's principle, which explains how a change in conditions—in concentration, pressure, or temperature or by addition of a catalyst—affects the equilibrium state, and we apply this principle to a major industrial process.
- › We introduce equilibrium concepts operating in metabolic pathways.

### 17.1 THE EQUILIBRIUM STATE AND THE EQUILIBRIUM CONSTANT

Experimental results from countless reactions have shown that, *given sufficient time, the concentrations of reactants and products attain certain values that no longer change*. This apparent cessation of chemical change occurs because *all reactions are reversible and reach a state of equilibrium*. Let's examine a chemical system at the

macroscopic and molecular levels to see how equilibrium arises and then consider some quantitative aspects of the process.

1. *A macroscopic view of equilibrium.* The system we'll consider is the reversible gaseous reaction between colorless dinitrogen tetroxide and brown nitrogen dioxide:

As soon as we introduce some liquid  $\text{N}_2\text{O}_4$  (bp = 21°C) into a sealed container kept at 200°C (473 K), it vaporizes, and the gas begins to turn pale brown as  $\text{NO}_2$  is produced. As time passes, the brown darkens, until, after more time, the color stops changing. The first three photos in Figure 17.1 show the color change, and the last photo shows no further change.

2. *A molecular view of equilibrium.* On the molecular level, as shown in the blow-up circles of Figure 17.1, a dynamic scene unfolds:

- The  $\text{N}_2\text{O}_4$  molecules fly wildly throughout the container, a few splitting into two  $\text{NO}_2$  molecules.
- As time passes, more  $\text{N}_2\text{O}_4$  molecules decompose and the concentration of  $\text{NO}_2$  rises.
- As the number of  $\text{N}_2\text{O}_4$  molecules decreases,  $\text{N}_2\text{O}_4$  decomposition slows down (recall that reaction rate decreases with decreasing reactant concentration for most reactions).
- At the same time, as the number of  $\text{NO}_2$  molecules increases, more collide, and formation of  $\text{N}_2\text{O}_4$  (the reverse reaction) speeds up.
- Eventually, the system reaches equilibrium:  $\text{N}_2\text{O}_4$  molecules are decomposing into  $\text{NO}_2$  molecules just as fast as  $\text{NO}_2$  molecules are forming  $\text{N}_2\text{O}_4$ .

Thus, at equilibrium, *reactant and product concentrations are constant because a change in one direction is balanced by a change in the other as the forward and reverse rates become equal:*

$$\text{At equilibrium: } \text{rate}_{\text{fwd}} = \text{rate}_{\text{rev}} \quad (17.1)$$

3. *A quantitative view of equilibrium: a constant ratio of constants.* Let's see how reactant and product concentrations affect this process. At a particular temperature, when the system reaches equilibrium, we have

$$\text{rate}_{\text{fwd}} = \text{rate}_{\text{rev}}$$

In this reaction system, both forward and reverse reactions are elementary steps (Section 16.6), so we can write their rate laws directly from the balanced equation:

$$k_{\text{fwd}}[\text{N}_2\text{O}_4]_{\text{eq}} = k_{\text{rev}}[\text{NO}_2]_{\text{eq}}^2$$

**Figure 17.1** Reaching equilibrium on the macroscopic and molecular levels.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

The reaction mixture consists mostly of colorless  $\text{N}_2\text{O}_4$ .

As  $\text{N}_2\text{O}_4$  decomposes to  $\text{NO}_2$ , the mixture becomes pale brown.

The brown color deepens as more  $\text{N}_2\text{O}_4$  decomposes and more  $\text{NO}_2$  is produced, until the color reaches a maximum at equilibrium.

The reaction continues in both directions at equal rates, so the concentrations of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  and therefore the color, no longer change.

where  $k_{\text{fwd}}$  and  $k_{\text{rev}}$  are the forward and reverse rate constants, respectively, and the subscript “eq” refers to concentrations at equilibrium. By rearranging, we set the ratio of the rate constants equal to the ratio of the concentration terms:

$$\frac{k_{\text{fwd}}}{k_{\text{rev}}} = \frac{[\text{NO}_2]_{\text{eq}}^2}{[\text{N}_2\text{O}_4]_{\text{eq}}}$$

The ratio of rate constants creates a new constant called the **equilibrium constant ( $K$ )**:

$$K = \frac{k_{\text{fwd}}}{k_{\text{rev}}} = \frac{[\text{NO}_2]_{\text{eq}}^2}{[\text{N}_2\text{O}_4]_{\text{eq}}} \quad (17.2)$$

Thus,  $K$  is a number equal to a particular ratio of equilibrium concentrations of product(s) and reactant(s) at a particular temperature.

4.  $K$  as a measure of reaction extent. The magnitude of  $K$  is an indication of how far a reaction proceeds toward product at a given temperature. Different reactions, even at the same temperature, have a wide range of concentrations at equilibrium—from almost all reactant to almost all product—and so, they have a wide range of equilibrium constants. Here are three examples of different magnitudes of  $K$ :

- **Small  $K$**  (Figure 17.2A). If a reaction yields little product before reaching equilibrium, the ratio of product concentration to reactant concentration is small, and the reaction has a small  $K$ ; if  $K$  is very small, we may say there is “no reaction.” For example, there is “no reaction” between nitrogen and oxygen at 1000 K:\*

- **Large  $K$**  (Figure 17.2B). Conversely, if a reaction reaches equilibrium with little reactant remaining, its ratio of product concentration to reactant concentration is large, and it has a large  $K$ ; if  $K$  is very large, we say the reaction “goes to completion.” The oxidation of carbon monoxide “goes to completion” at 1000 K:

- **Intermediate  $K$**  (Figure 17.2C). When significant amounts of both reactant and product are present at equilibrium,  $K$  has an intermediate value, as when bromine monochloride breaks down to its elements at 1000 K:

**Figure 17.2** The range of equilibrium constants.

## › Summary of Section 17.1

- › Kinetics and equilibrium are distinct aspects of a reaction system, and the rate and extent of a reaction are not necessarily related.
- › When the forward and reverse reactions occur at the same rate, concentrations no longer change and the system has reached equilibrium.
- › The equilibrium constant ( $K$ ) is a number based on a particular ratio of product and reactant concentrations:  $K$  is small if a high concentration of reactant(s) is present at equilibrium, and it is large if a high concentration of product(s) is present at equilibrium.

\*Note that the equilibrium constant is represented by a capital italic  $K$ , whereas the temperature unit, the kelvin, is a capital roman  $K$ . Also, since the kelvin is a unit, it always follows a number.

## 17.2 THE REACTION QUOTIENT AND THE EQUILIBRIUM CONSTANT

We have introduced the equilibrium constant in terms of a ratio of rate constants, but the original research on chemical equilibrium was developed many years before the principles of kinetics. In 1864, two Norwegian chemists, Cato Guldberg and Peter Waage, observed that *at a given temperature, a chemical system reaches a state in which a particular ratio of reactant and product concentrations has a constant value.* This is a statement of the **law of chemical equilibrium**, or the **law of mass action**.

### The Changing Value of the Reaction Quotient

The particular ratio of concentration terms that we write for a given reaction is called the **reaction quotient** ( $Q$ ) (also known as the *mass-action expression*). For the reversible breakdown of  $\text{N}_2\text{O}_4$  to  $\text{NO}_2$ , the reaction quotient is

As the reaction proceeds toward equilibrium, the concentrations of reactants and products change continually, and so does their ratio, which is the value of  $Q$ : at a given temperature, at the beginning of the reaction, the concentrations have initial values, and  $Q$  has an initial value; a moment later, the concentrations have slightly different values, and so does  $Q$ ; after another moment, the concentrations and the value of  $Q$  change further. These changes continue, *until the system reaches equilibrium*. At that point, reactant and product concentrations have their equilibrium values and no longer change. Thus, the value of  $Q$  no longer changes and equals  $K$  at that temperature:

$$\text{At equilibrium: } Q = K \quad (17.3)$$

In formulating the law of mass action, Guldberg and Waage found that, *for a particular system and temperature, the same equilibrium state is attained regardless of starting concentrations.* For example, for the  $\text{N}_2\text{O}_4$ - $\text{NO}_2$  system at  $200^\circ\text{C}$  (473 K), the data from four experiments appear in Table 17.1. Two essential points stand out:

- The ratio of *initial* concentrations (*fourth column*) varies widely but always gives the same ratio of *equilibrium* concentrations (*rightmost column*).
- The *individual* equilibrium concentrations are different in each case, but the *ratio* of these equilibrium concentrations is constant.

Thus, monitoring  $Q$  tells us whether the system has reached equilibrium or, if it hasn't, how far away it is and in which direction it is changing.

Table 17.1

Initial and Equilibrium Concentration Ratios for the  $\text{N}_2\text{O}_4$ - $\text{NO}_2$  System at  $200^\circ\text{C}$  (473 K)

Expt	Initial			Equilibrium		
	$[\text{N}_2\text{O}_4]$	$[\text{NO}_2]$	$Q, [\text{NO}_2]^2/[\text{N}_2\text{O}_4]$	$[\text{N}_2\text{O}_4]_{\text{eq}}$	$[\text{NO}_2]_{\text{eq}}$	$K, [\text{NO}_2]_{\text{eq}}^2/[\text{N}_2\text{O}_4]_{\text{eq}}$
1	0.1000	0.0000	$\frac{(0.0000)^2}{(0.1000)} = 0.0000$	0.00357	0.193	$\frac{(0.193)^2}{(0.00357)} = 10.4$
2	0.0000	0.1000	$\frac{(0.1000)^2}{(0.0000)} = \infty$	0.000924	0.0982	$\frac{(0.0982)^2}{(0.000924)} = 10.4$
3	0.0500	0.0500	$\frac{(0.0500)^2}{(0.0500)} = 0.0500$	0.00204	0.146	$\frac{(0.146)^2}{(0.00204)} = 10.4$
4	0.0750	0.0250	$\frac{(0.0250)^2}{(0.0750)} = 0.00833$	0.00275	0.170	$\frac{(0.170)^2}{(0.00275)} = 10.5$

The curves in Figure 17.3 show experiment 1 in Table 17.1. Note that  $[\text{N}_2\text{O}_4]$  and  $[\text{NO}_2]$  change smoothly during the course of the reaction (as indicated by the changing brown color at the top), and so does the value of  $Q$ . Once the system reaches equilibrium (constant brown color), the concentrations no longer change and  $Q$  equals  $K$ . In other words, for any given chemical system,  $K$  is a special value of  $Q$  that occurs when the reactant and product concentrations have their equilibrium values.

## Writing the Reaction Quotient in Its Various Forms

The reaction quotient *must* be written directly from the balanced equation. In contrast, as discussed in Chapter 16, the rate law for an overall reaction *cannot* be written from the balanced equation, but must be determined from rate data.

**Constructing the Reaction Quotient** The most common form of the reaction quotient shows reactant and product terms as molar concentrations, which are designated by square brackets,  $[ ]$ . Thus, from now on, we designate the *reaction quotient based on concentrations* as  $Q_c$ . (We also designate the *equilibrium constant based on concentrations* as  $K_c$ .) For the general equation

where  $a$ ,  $b$ ,  $c$ , and  $d$  are the stoichiometric coefficients, the reaction quotient is

$$Q_c = \frac{[\text{C}]^c[\text{D}]^d}{[\text{A}]^a[\text{B}]^b} \quad (17.4)$$

Thus,  $Q$  is a ratio consisting of product concentration terms multiplied together and divided by reactant concentration terms multiplied together, with each term raised to the power of its balancing coefficient.

Two steps are needed to construct a reaction quotient for any chemical system:

1. *Start with the balanced equation.* For example, for the formation of ammonia from its elements, the balanced equation (with colored coefficients for reference) is

2. *Arrange the terms and exponents.* Place the product terms in the numerator and the reactant terms in the denominator, multiplied by each other, and raise each term to the power of its balancing coefficient (colored as in the balanced equation):

$$Q_c = \frac{[\text{NH}_3]^2}{[\text{N}_2][\text{H}_2]^3}$$

**Why  $Q$  and  $K$  Have No Units** In this text (and most others), *the values of  $Q$  and  $K$  are unitless numbers*. As we will discuss in Chapter 20, the reason is that  $Q$  and  $K$  are based on thermodynamic parameters. That is, each term in  $Q$  or  $K$  is actually an *activity*, or active concentration, the *ratio* of the concentration (or pressure) of a substance to its reference standard-state concentration (or pressure). Recall from Section 6.6 that the standard states are 1  $M$  for a substance in solution, 1 atm for a gas, and the pure substance itself for a liquid or solid. The terms in  $Q$  or  $K$  thus become unitless as follows:

- For a concentration of, say, 1.20  $M$  NaCl, we have

$$[\text{NaCl}] = \frac{1.20 \text{ M (measured quantity)}}{1 \text{ M (standard-state quantity)}} = 1.20$$

- For a pressure of, say, 0.53 atm  $\text{N}_2$ , we have

$$P_{\text{N}_2} = \frac{0.53 \text{ atm (measured quantity)}}{1 \text{ atm (standard-state quantity)}} = 0.53$$

- For a pure solid or a pure liquid, the concentration is the density of the substance, which when divided by its density, must equal 1.

Since each term used to write  $Q$  or  $K$  is a unitless ratio,  $Q$  and  $K$  are unitless also.

**Figure 17.3** The change in  $Q$  during the  $\text{N}_2\text{O}_4\text{-NO}_2$  reaction. Based on data from Experiment 1 in Table 17.1.

**Figure 17.4** The reaction quotient for a heterogeneous system depends only on concentrations that change.

**Form of  $Q$  for a Reaction Involving Pure Liquids or Solids** The formation of gaseous  $\text{NH}_3$  from its elements in the gas phase is an example of a *homogeneous* equilibrium system in which all the components are in the same phase. When the components are in different phases, the equilibrium system is *heterogeneous*.

Consider the decomposition of limestone to lime and carbon dioxide:

Using the rules for writing the reaction quotient, we would obtain

$$Q_c = \frac{[\text{CaO}][\text{CO}_2]}{[\text{CaCO}_3]}$$

However, as the preceding subsection about  $Q$  and  $K$  being unitless numbers stated, each term in the reaction quotient is actually the ratio of the measured quantity to the standard-state quantity and *for all pure solids and liquids, this ratio is 1*. Thus, we have

$$Q_c = \frac{(1)[\text{CO}_2]}{(1)} = [\text{CO}_2]$$

This means that as long as some  $\text{CaO}$  and some  $\text{CaCO}_3$  are present, only the  $\text{CO}_2$  concentration affects the value of  $Q_c$  (Figure 17.4).

It makes sense that *we eliminate the terms for pure solids and liquids in the expressions for  $Q$  and  $K$*  because we are concerned only with concentrations that *change* as they approach equilibrium, and the concentrations, like the densities, of pure solids and liquids are constant.

#### SAMPLE PROBLEM 17.1

#### Writing the Reaction Quotient from the Balanced Equation

**Problem** Write the reaction quotient,  $Q_c$ , for each of the following reactions:

- (a)  $\text{N}_2\text{O}_5(g) \rightleftharpoons \text{NO}_2(g) + \text{O}_2(g)$   
 (b)  $\text{Na}(s) + \text{H}_2\text{O}(l) \rightleftharpoons \text{NaOH}(aq) + \text{H}_2(g)$   
 (c)  $\text{C}_3\text{H}_8(g) + \text{O}_2(g) \rightleftharpoons \text{CO}_2(g) + \text{H}_2\text{O}(g)$

**Plan** We balance the equation and then construct the reaction quotient using Equation 17.4. Remember that concentration terms for pure liquids and solids are *not* included in the reaction quotient.

**Solution** (a) From the balanced equation,  $2\text{N}_2\text{O}_5(g) \rightleftharpoons 4\text{NO}_2(g) + \text{O}_2(g)$ , we have

$$Q_c = \frac{[\text{NO}_2]^4 [\text{O}_2]}{[\text{N}_2\text{O}_5]^2}$$

(b) The solid  $\text{Na}$  and pure liquid  $\text{H}_2\text{O}$  are not included in the reaction quotient.  $\text{NaOH}(aq)$  is a solution in the liquid phase, but it is included in the reaction quotient since it is not a

pure liquid. From the balanced equation,  $2\text{Na}(s) + 2\text{H}_2\text{O}(l) \rightleftharpoons 2\text{NaOH}(aq) + \text{H}_2(g)$ , we have

$$Q_c = [\text{NaOH}]^2[\text{H}_2]$$

(c) From the balanced equation,  $\text{C}_3\text{H}_8(g) + 5\text{O}_2(g) \rightleftharpoons 3\text{CO}_2(g) + 4\text{H}_2\text{O}(g)$ , we have

$$Q_c = \frac{[\text{CO}_2]^3[\text{H}_2\text{O}]^4}{[\text{C}_3\text{H}_8][\text{O}_2]^5}$$

**Check** Be sure that the exponents in the reaction quotient are the same as the balancing coefficients. A good check is to reverse the process and see if you obtain the balanced equation, except for any substances that are pure liquids or solids: change the numerator of the expression to products, the denominator to reactants, and the exponents to coefficients.

### FOLLOW-UP PROBLEMS

*Brief Solutions for all Follow-up Problems appear at the end of the chapter.*

**17.1A** Write the reaction quotient,  $Q_c$ , for each of the following reactions:

**17.1B** Write the reaction quotient,  $Q_c$ , for each of the following reactions:

**SOME SIMILAR PROBLEMS** 17.12–17.15 and 17.18–17.21

**Form of Q for a Forward and a Reverse Reaction** The form of the reaction quotient depends on the *direction* in which the balanced equation is written. Consider, for example, the oxidation of sulfur dioxide to sulfur trioxide. This reaction is a key step in acid-rain formation and sulfuric acid production. The balanced equation is

The reaction quotient for this equation *as written* is

$$Q_{c(\text{fwd})} = \frac{[\text{SO}_3]^2}{[\text{SO}_2]^2[\text{O}_2]}$$

If we had written the reverse reaction, the decomposition of sulfur trioxide,

the reaction quotient would be the *reciprocal* of  $Q_{c(\text{fwd})}$ :

$$Q_{c(\text{rev})} = \frac{[\text{SO}_2]^2[\text{O}_2]}{[\text{SO}_3]^2} = \frac{1}{Q_{c(\text{fwd})}}$$

Thus, a reaction quotient (or equilibrium constant) for a forward reaction is the **reciprocal** of the reaction quotient (or equilibrium constant) for the reverse reaction:

$$Q_{c(\text{fwd})} = \frac{1}{Q_{c(\text{rev})}} \quad \text{and} \quad K_{c(\text{fwd})} = \frac{1}{K_{c(\text{rev})}} \quad (17.5)$$

The  $K_c$  values for the forward and reverse reactions shown above at 1000 K are

$$K_{c(\text{fwd})} = \frac{[\text{SO}_3]^2}{[\text{SO}_2]^2[\text{O}_2]} = 261 \quad \text{and} \quad K_{c(\text{rev})} = \frac{[\text{SO}_2]^2[\text{O}_2]}{[\text{SO}_3]^2} = \frac{1}{K_{c(\text{fwd})}} = \frac{1}{261} = 3.83 \times 10^{-3}$$

These values make sense: if the forward reaction goes far to the right (high  $K_c$ ), yielding a large concentration of the product  $\text{SO}_3$  at equilibrium, the reverse reaction does not go far to the right (low  $K_c$ ), again resulting in a large concentration of unreacted  $\text{SO}_3$  when equilibrium is reached.

**Form of  $Q$  for a Reaction with Coefficients Multiplied by a Common Factor** Multiplying all the coefficients of the equation by some factor also changes the form of  $Q$ . For example, multiplying all the coefficients in the equation for the formation of  $\text{SO}_3$  by  $\frac{1}{2}$  gives

For this equation, the reaction quotient is

$$Q'_{c(\text{fwd})} = \frac{[\text{SO}_3]}{[\text{SO}_2][\text{O}_2]^{1/2}}$$

Notice that  $Q_c$  for the halved equation equals  $Q_c$  for the original equation raised to the  $\frac{1}{2}$  power:

$$Q'_{c(\text{fwd})} = Q_{c(\text{fwd})}^{1/2} = \left( \frac{[\text{SO}_3]^2}{[\text{SO}_2]^2[\text{O}_2]} \right)^{1/2} = \frac{[\text{SO}_3]}{[\text{SO}_2][\text{O}_2]^{1/2}}$$

Once again, the same property holds for the equilibrium constants. Relating the halved reaction to the original, we have

$$K'_{c(\text{fwd})} = K_{c(\text{fwd})}^{1/2} = (261)^{1/2} = 16.2$$

It may seem that we have changed the extent of the reaction, as indicated by a different  $K$ , just by changing the coefficients of the equation, but that can't be true. A particular  $K$  has meaning only in relation to a particular equation. If  $K_{c(\text{fwd})}$  and  $K'_{c(\text{fwd})}$  relate to different equations, we cannot compare them directly.

In general, if all the coefficients of the balanced equation are multiplied by some factor, that factor becomes the exponent for relating the reaction quotients and the equilibrium constants. For a multiplying factor  $n$ , which we can write as

the reaction quotient and equilibrium constant are

$$Q' = Q^n = \left( \frac{[\text{C}]^c[\text{D}]^d}{[\text{A}]^a[\text{B}]^b} \right)^n \quad \text{and} \quad K' = K^n \quad (17.6)$$

**Form of  $Q$  for an Overall Reaction** We follow the same procedure for writing a reaction quotient whether an equation represents an individual reaction step or an overall multistep reaction. If an overall reaction is the **sum** of two or more reactions, the overall reaction quotient (or equilibrium constant) is the **product** of the reaction quotients (or equilibrium constants) for the steps:

$$Q_{\text{overall}} = Q_1 \times Q_2 \times Q_3 \times \dots$$

and

$$K_{\text{overall}} = K_1 \times K_2 \times K_3 \times \dots \quad (17.7)$$

Sample Problem 17.2 demonstrates calculations involving  $K$  values for reactions that are reversed or multiplied by a factor, and for an overall reaction.

### SAMPLE PROBLEM 17.2

#### Finding $K$ for Reactions Multiplied by a Common Factor or Reversed and for an Overall Reaction

**Problem** A chemist wants to find  $K_c$  for the following reaction at 700 K:

Use the following data at 700 K to find the unknown  $K_c$ :

**Plan** We must manipulate reactions (1) and (2) so that they add together to give the target reaction. Reaction (1) must be reversed; the new equilibrium constant ( $K'_{c1}$ ) is the reciprocal of  $K_{c1}$ . Reaction (2) must be multiplied by 3; the new equilibrium constant ( $K'_{c2}$ ) is  $K_{c2}$  raised to the third power. We then add the two manipulated reactions and multiply their  $K_c$  values to obtain the overall  $K_c$ .

**Solution** Reaction (1) must be reversed since  $2\text{NH}_3$  is a reactant in the target reaction; the  $K_c$  value of the reversed reaction is the reciprocal of the original  $K_c$ :

Reaction (2) must be multiplied by 3 (in the target reaction  $\text{I}_2$  has a coefficient of 3 and HI has a coefficient of 6) so the new  $K_c$  value equals the original  $K_c$  value raised to the third power:

Adding the two reactions (cancelling common terms):

Multiplying the individual reaction quotients and calculating the overall  $K_c$ :

$$Q'_{c1} \times Q'_{c2} = \frac{[\text{N}_2][\text{H}_2]^3}{[\text{NH}_3]^2} \times \frac{[\text{HI}]^6}{[\text{H}_2]^3[\text{I}_2]^3} = \frac{[\text{N}_2][\text{HI}]^6}{[\text{NH}_3]^2[\text{I}_2]^3} = Q_{c(\text{overall})}$$

$$K_{c(\text{overall})} = K'_{c1} \times K'_{c2} = (2.92)(1.6 \times 10^5) = 4.7 \times 10^5$$

**Check** Round off and check the calculation of the overall  $K_c$  value:

$$K_c \approx (3)(2 \times 10^5) = 6 \times 10^5$$

### FOLLOW-UP PROBLEMS

**17.2A** Find the  $K_c$  value of the following reaction at 1123 K

using the following data at the same temperature:

**17.2B** The reaction  $2\text{NO}(g) + \text{Br}_2(g) \rightleftharpoons 2\text{NOBr}(g)$  has a  $K_c$  value of  $1.3 \times 10^{-2}$  at 1000 K. Calculate  $K_c$  for the following reactions:

**SOME SIMILAR PROBLEMS** 17.16, 17.17, 17.23, and 17.24

Table 17.2 summarizes the ways of writing  $Q$  and calculating  $K$ .

Form of Chemical Equations	Form of $Q$	Value of $K$
Reference reaction (ref): $A \rightleftharpoons B$	$Q_{(\text{ref})} = \frac{[B]}{[A]}$	$K_{(\text{ref})} = \frac{[B]_{\text{eq}}}{[A]_{\text{eq}}}$
Reverse reaction: $B \rightleftharpoons A$	$Q = \frac{1}{Q_{(\text{ref})}} = \frac{[A]}{[B]}$	$K = \frac{1}{K_{(\text{ref})}}$
Coefficients multiplied by $n$	$Q = Q_{(\text{ref})}^n$	$K = K_{(\text{ref})}^n$
Reaction as sum of two steps:		
(1) $A \rightleftharpoons C$	$Q_1 = \frac{[C]}{[A]}$	
(2) $C \rightleftharpoons B$	$Q_2 = \frac{[B]}{[C]}$	
	$Q_{\text{overall}} = Q_1 \times Q_2 = Q_{(\text{ref})}$	$K_{\text{overall}} = K_1 \times K_2$
	$= \frac{[C]}{[A]} \times \frac{[B]}{[C]} = \frac{[B]}{[A]}$	$= K_{(\text{ref})}$
Reaction with pure solid or liquid component, such as $A(s)$	$Q = Q_{(\text{ref})}(1) = [B]$	$K = K_{(\text{ref})}(1) = [B]$

## › Summary of Section 17.2

- › The reaction quotient based on concentration,  $Q_c$ , is a particular ratio of product to reactant concentrations. The value of  $Q_c$  changes as the reaction proceeds. When the system reaches equilibrium at a particular temperature,  $Q_c = K_c$ .
- › The concentration terms for pure liquids or solids do not appear in  $Q$  because they are equal to 1.
- › The *form* of  $Q$  is based on the balanced equation exactly as written, so it changes if the equation is reversed or multiplied by some factor, and  $K$  changes accordingly.
- › If a reaction is the sum of two or more steps, the overall  $Q$  (or  $K$ ) is the product of the individual  $Q$ 's (or  $K$ 's).
- › Three criteria define a system at equilibrium:
  1. Reactant and product concentrations are constant over time.
  2. The opposing reaction rates are equal:  $\text{rate}_{\text{fwd}} = \text{rate}_{\text{rev}}$ .
  3. The reaction quotient equals the equilibrium constant:  $Q = K$ .

## 17.3 EXPRESSING EQUILIBRIA WITH PRESSURE TERMS: RELATION BETWEEN $K_c$ AND $K_p$

It is easier to measure gas *pressure* than concentration, so when a reaction involves gases, we often express the reaction quotient in terms of partial pressures instead of concentrations. As long as the gases behave nearly ideally during the experiment, the ideal gas law (Section 5.3) allows us to relate pressure ( $P$ ) to molar concentration ( $n/V$ ):

$$PV = nRT, \quad \text{so} \quad P = \frac{n}{V} RT \quad \text{or} \quad \frac{P}{RT} = \frac{n}{V}$$

Thus, at constant  $T$ , *pressure is directly proportional to molar concentration*. For example, in the reaction between gaseous NO and O<sub>2</sub>,

the *reaction quotient based on pressures*,  $Q_p$ , is

$$Q_p = \frac{P_{\text{NO}_2}^2}{P_{\text{NO}}^2 \times P_{\text{O}_2}}$$

The equilibrium constant obtained when all components are present at their equilibrium partial pressures is designated  $K_p$ , the *equilibrium constant based on pressures*. In many cases,  $K_p$  has a value different from  $K_c$ . But if you know one of these values, the *change in amount (mol) of gas*,  $\Delta n_{\text{gas}}$ , from the balanced equation allows you to calculate the other. Let's see how this conversion works for the oxidation of NO:

As the balanced equation shows,

With  $\Delta$  meaning “final *minus* initial” (products *minus* reactants), we have

$$\Delta n_{\text{gas}} = \text{moles of gaseous product} - \text{moles of gaseous reactant} = 2 - 3 = -1$$

Keep this value of  $\Delta n_{\text{gas}}$  in mind because it appears in the conversion that follows.

The reaction quotient based on concentrations is

$$Q_c = \frac{[\text{NO}_2]^2}{[\text{NO}]^2 [\text{O}_2]}$$

Rearranging the ideal gas law to  $n/V = P/RT$ , we write the terms in square brackets as  $n/V$  and convert them to partial pressures,  $P$ ; then we collect the  $RT$  terms and cancel:

$$\begin{aligned} Q_c &= \frac{\frac{n_{\text{NO}_2}^2}{V^2}}{\frac{n_{\text{NO}}^2}{V^2} \times \frac{n_{\text{O}_2}}{V}} = \frac{\frac{P_{\text{NO}_2}^2}{(RT)^2}}{\frac{P_{\text{NO}}^2}{(RT)^2} \times \frac{P_{\text{O}_2}}{RT}} = \frac{P_{\text{NO}_2}^2}{P_{\text{NO}}^2 \times P_{\text{O}_2}} \times \frac{\frac{1}{(RT)^2}}{\frac{1}{(RT)^2} \times \frac{1}{RT}} \\ &= \frac{P_{\text{NO}_2}^2}{P_{\text{NO}}^2 \times P_{\text{O}_2}} \times RT \end{aligned}$$

Note that the far right side of the previous expression is  $Q_p$  multiplied by  $RT$ . Thus,

$$Q_c = Q_p(RT)$$

Also, at equilibrium,  $K_c = K_p(RT)$ ; and, solving for  $K_p$  gives

$$K_p = \frac{K_c}{RT} = K_c(RT)^{-1}$$

Note especially that *the exponent of the RT term equals the change in the amount (mol) of gas ( $\Delta n_{\text{gas}}$ ) from the balanced equation*,  $-1$  in this case. Thus, in general, we have

$$K_p = K_c(RT)^{\Delta n_{\text{gas}}} \quad (17.8)$$

Based on Equation 17.8, *if the amount (mol) of gas does not change in the reaction*,  $\Delta n_{\text{gas}} = 0$ , and the  $RT$  term drops out (i.e., equals 1); then,  $K_p = K_c$ . (In calculations, be sure the units for  $R$  are consistent with units for pressure.)

### SAMPLE PROBLEM 17.3

### Converting Between $K_c$ and $K_p$

**Problem** Ammonium hydrosulfide decomposes to ammonia and hydrogen sulfide gases. Find  $K_c$  for the decomposition reaction:

**Plan** We know  $K_p$  (0.19), so to convert between  $K_p$  and  $K_c$ , we must first determine  $\Delta n_{\text{gas}}$  from the balanced equation. Then we rearrange Equation 17.8. If we assume that pressure is measured in atmospheres,  $R = 0.0821 \text{ atm}\cdot\text{L/mol}\cdot\text{K}$ ; the given temperature must be converted to kelvins.

**Solution** Determining  $\Delta n_{\text{gas}}$ : There are 2 moles of gaseous product (1 mol  $\text{NH}_3$  and 1 mol  $\text{H}_2\text{S}$ ) and no gaseous reactant, so  $\Delta n_{\text{gas}} = 2 - 0 = 2$ . (Note that only moles of *gaseous* reactants and products are used to determine  $\Delta n_{\text{gas}}$ .)

Converting  $T$  from  $^\circ\text{C}$  to K:  $T (\text{K}) = 218^\circ\text{C} + 273.15 = 491 \text{ K}$

Rearranging Equation 17.8 and calculating  $K_c$ :

$$K_p = K_c(RT)^{\Delta n_{\text{gas}}} \quad \text{or} \quad K_p = K_c(RT)^2$$

so

$$\begin{aligned} K_c &= K_p(RT)^{-2} = (0.19)(0.0821 \times 491)^{-2} \\ &= 1.2 \times 10^{-4} \end{aligned}$$

**Check** Rounding gives

$$(0.2)(0.1 \times 500)^{-2} = (0.2)(4 \times 10^{-4}) = 0.8 \times 10^{-4}$$

## 17.4

## COMPARING Q AND K TO DETERMINE REACTION DIRECTION

Suppose you have a mixture of reactants and products and you know  $K$  at the temperature of the reaction. By comparing the value of  $Q$  with the known value of  $K$ , you can tell whether the reaction has reached equilibrium or, if not, in which direction

it is progressing. The value of  $K$  remains constant at a particular temperature, but as we've seen, the value of  $Q$  varies as the concentrations of reactants and products change. Since  $Q$  has product terms in the numerator and reactant terms in the denominator, *more product makes  $Q$  larger, and more reactant makes  $Q$  smaller*:

$$Q = \frac{[\text{product}]}{[\text{reactant}]}$$

increase in [product] → larger  $Q$   
 increase in [reactant] → smaller  $Q$

There are three possibilities for the relative sizes of  $Q$  and  $K$  (Figure 17.5):

- $Q < K$ . If  $Q$  is smaller than  $K$ , the denominator (reactants) is large relative to the numerator (products). For  $Q$  to equal  $K$ , the reactants must decrease and the products increase. The reaction is not at equilibrium and will progress to the right, toward products, until  $Q = K$ :

If  $Q < K$ , reactants  $\rightarrow$  products

- $Q > K$ . If  $Q$  is larger than  $K$ , the numerator (products) will decrease and the denominator (reactants) will increase. The reaction is not at equilibrium and will progress to the left, toward reactants, until  $Q = K$ :

If  $Q > K$ , reactants  $\leftarrow$  products

- $Q = K$ . This situation occurs when the reactant and product terms equal their equilibrium values. The reaction is at equilibrium, and no further net change takes place:

If  $Q = K$ , reactants  $\rightleftharpoons$  products

**Figure 17.5** Reaction direction and the relative sizes of  $Q$  and  $K$ . When  $Q_c$  is smaller or larger than  $K_c$ , the reaction continues until  $Q_c = K_c$ . Note that  $K_c$  remains the same throughout.

Sample Problem 17.4 relies on molecular scenes to determine reaction direction, and Sample Problem 17.5 uses concentration data.

### SAMPLE PROBLEM 17.4

### Using Molecular Scenes to Determine Reaction Direction

**Problem** For the reaction  $A(g) \rightleftharpoons B(g)$ , the equilibrium mixture at  $175^\circ\text{C}$  is  $[A] = 2.8 \times 10^{-4} M$  and  $[B] = 1.2 \times 10^{-4} M$ . The molecular scenes below represent four different mixtures for the reaction (A is red; B is blue). For each mixture, does the reaction progress to the right or to the left or neither to reach equilibrium?

**Plan** We must compare  $Q_c$  with  $K_c$  to determine the reaction direction, so we first use the given equilibrium concentrations to find  $K_c$ . Then we count spheres and calculate  $Q_c$  for each mixture. If  $Q_c < K_c$ , the reaction progresses to the right (reactants to products); if  $Q_c > K_c$ , it progresses to the left (products to reactants); and if  $Q_c = K_c$ , there is no further net change.

**Solution** Writing the reaction quotient and using the data to find  $K_c$ :

$$Q_c = \frac{[B]}{[A]} = \frac{1.2 \times 10^{-4}}{2.8 \times 10^{-4}} = 0.43 = K_c$$

Counting red (A) and blue (B) spheres to calculate  $Q_c$  for each mixture:

$$1. Q_c = 8/2 = 4.0 \quad 2. Q_c = 3/7 = 0.43 \quad 3. Q_c = 4/6 = 0.67 \quad 4. Q_c = 2/8 = 0.25$$

Comparing  $Q_c$  with  $K_c$  to determine reaction direction:

$$1. Q_c > K_c: \text{ left} \quad 2. Q_c = K_c: \text{ no net change} \quad 3. Q_c > K_c: \text{ left} \quad 4. Q_c < K_c: \text{ right}$$

**Check** Making an error in the calculation for  $K_c$  would lead to incorrect conclusions throughout, so check that step: the exponents are the same, and  $1.2/2.8$  is a bit less than 0.5, as is the calculated  $K_c$ . You can check the final answers by inspection; for example, for the number of B (8) in mixture 1 to equal the number at equilibrium (3), more B must change to A, so the reaction must proceed to the left.

### FOLLOW-UP PROBLEMS

**17.4A** At 338 K, the reaction  $X(g) \rightleftharpoons Y(g)$  has a  $K_c$  of 1.4. The scenes below represent different mixtures at 338 K, with X *orange* and Y *green*. In which direction does the reaction proceed (if there is any net change) for each mixture to reach equilibrium?

**17.4B** Scene 1 below represents the reaction  $2C(g) \rightleftharpoons D(g)$  at equilibrium at 25°C (C is *yellow* and D is *blue*). Scenes 2 and 3 represent two different mixtures of C and D at 25°C. Calculate  $K_c$  for the reaction, and determine in which direction the reaction proceeds (if there is any net change) for the mixtures in scenes 2 and 3.

### A SIMILAR PROBLEM 17.35

#### SAMPLE PROBLEM 17.5

#### Using Concentrations to Determine Reaction Direction

**Problem** For the reaction  $N_2O_4(g) \rightleftharpoons 2NO_2(g)$ ,  $K_c = 0.21$  at 100°C. At a point during the reaction,  $[N_2O_4] = 0.12 M$  and  $[NO_2] = 0.55 M$ . Is the reaction at equilibrium at that time? If not, in which direction is it progressing?

**Plan** We write  $Q_c$ , find its value by substituting the given concentrations, and compare its value with the given  $K_c$ .

**Solution** Writing the reaction quotient and solving for  $Q_c$ :

$$Q_c = \frac{[NO_2]^2}{[N_2O_4]} = \frac{(0.55)^2}{0.12} = 2.5$$

With  $Q_c > K_c$  ( $2.5 > 0.21$ ), the reaction is not at equilibrium and will proceed to the left until  $Q_c = K_c$ .

**Check** With  $[\text{NO}_2] > [\text{N}_2\text{O}_4]$ , we expect to obtain a value for  $Q_c$  that is greater than 0.21. If  $Q_c > K_c$ , the numerator will decrease and the denominator will increase until  $Q_c = K_c$ ; that is, this reaction will proceed toward reactants.

### FOLLOW-UP PROBLEMS

**17.5A** Chloromethane forms by the reaction

At 1500 K,  $K_p = 1.6 \times 10^4$ . In the reaction mixture,  $P_{\text{CH}_4} = 0.13$  atm,  $P_{\text{Cl}_2} = 0.035$  atm,  $P_{\text{CH}_3\text{Cl}} = 0.24$  atm, and  $P_{\text{HCl}} = 0.47$  atm. Is  $\text{CH}_3\text{Cl}$  or  $\text{CH}_4$  forming?

**17.5B** Sulfur trioxide is produced by the reaction of sulfur dioxide with oxygen:

Suppose 3.4 mol of  $\text{SO}_2$ , 1.5 mol of  $\text{O}_2$ , and 1.2 mol of  $\text{SO}_3$  are placed in a 2.0-L flask. Is the system at equilibrium? If not, in which direction will the reaction proceed?

**SOME SIMILAR PROBLEMS** 17.36–17.38

## › Summary of Section 17.4

- › We compare the values of  $Q$  and  $K$  to determine the direction in which a reaction will proceed toward equilibrium.
  - If  $Q_c < K_c$ , more product forms.
  - If  $Q_c > K_c$ , more reactant forms.
  - If  $Q_c = K_c$ , there is no further net change.

## 17.5 HOW TO SOLVE EQUILIBRIUM PROBLEMS

Many kinds of equilibrium problems arise in the real world—and on chemistry exams—but we can group most of them into two types:

1. We know the equilibrium quantities of reactants and products and solve for  $K$ .
2. We know  $K$  and the initial quantities of reactants and products and solve for the equilibrium quantities.

### Using Quantities to Find the Equilibrium Constant

There are two common variations on this type of problem: one involves substituting equilibrium quantities into the reaction quotient to solve for  $K$ , and the other requires first finding some of the quantities.

**Substituting Equilibrium Quantities into  $Q$  to Find  $K$**  In this type of problem, we use given equilibrium quantities to calculate  $K$ . Suppose, for example, that equal amounts of gaseous hydrogen and iodine are injected into a 1.50-L flask at a fixed temperature. In time, the following equilibrium is attained:

At equilibrium, the flask contains 1.80 mol of  $\text{H}_2$ , 1.80 mol of  $\text{I}_2$ , and 0.520 mol of  $\text{HI}$ . We calculate  $K_c$  by finding the concentrations from the amounts and flask volume and substituting into the reaction quotient from the balanced equation:

$$Q_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]}$$

We divide each amount (mol) by the volume (L) to find each concentration (mol/L):

$$[\text{H}_2] = \frac{1.80 \text{ mol}}{1.50 \text{ L}} = 1.20 \text{ M}$$

Similarly,  $[I_2] = 1.20 M$ , and  $[HI] = 0.347 M$ . Substituting these values into the expression for  $Q_c$  gives  $K_c$ :

$$K_c = \frac{(0.347)^2}{(1.20)(1.20)} = 8.36 \times 10^{-2}$$

**Using a Reaction Table to Find Equilibrium Quantities and  $K$**  When some quantities are not given, we determine them from the reaction stoichiometry and then find  $K$ . In the following example, note the use of the *reaction table*.

In a study of carbon oxidation, an evacuated vessel containing a small amount of powdered graphite is heated to 1080 K. Gaseous  $CO_2$  is added to a pressure of 0.458 atm, and CO forms. At equilibrium, the total pressure is 0.757 atm. Calculate  $K_p$ .

As always, we start by writing the balanced equation and the reaction quotient:

The data are given in atmospheres and we must find  $K_p$ , so we write the expression for  $Q_p$ ; note that it does *not* include a term for the solid, C(graphite):

$$Q_p = \frac{P_{CO}^2}{P_{CO_2}}$$

We are given the initial  $P_{CO_2}$  and the  $P_{\text{total}}$  at equilibrium. To find  $K_p$ , we must find the equilibrium pressures of  $CO_2$  and CO and then substitute them into  $Q_p$ .

Let's think through what happened in the vessel. An unknown portion of the  $CO_2$  reacted with graphite to form an unknown amount of CO. We already know the *relative* amounts of  $CO_2$  and CO from the balanced equation: for each mole of  $CO_2$  that reacts, 2 mol of CO forms, which means that when  $x$  atm of  $CO_2$  reacts,  $2x$  atm of CO forms:

The pressure of  $CO_2$  at equilibrium,  $P_{CO_2(\text{eq})}$ , is the initial pressure,  $P_{CO_2(\text{init})}$ , *minus*  $x$ , the  $CO_2$  that reacts (the change in  $P_{CO_2}$  due to the reaction):

$$P_{CO_2(\text{init})} - x = P_{CO_2(\text{eq})} = 0.458 - x$$

Similarly, the pressure of CO at equilibrium,  $P_{CO(\text{eq})}$ , is the initial pressure,  $P_{CO(\text{init})}$ , *plus*  $2x$ , the CO that forms (the change in  $P_{CO}$  due to the reaction).  $P_{CO(\text{init})}$  is zero, so

$$P_{CO(\text{init})} + 2x = 0 + 2x = 2x = P_{CO(\text{eq})}$$

We'll summarize this information in a reaction table, similar to those in Chapter 3, but for "Final" quantities, we use those at equilibrium. The table shows the balanced equation at the top, and

- the *initial* quantities (concentrations or pressures) of reactants and products,
- the *changes* in these quantities during the reaction, and
- the *equilibrium* quantities.

Pressure (atm)	$CO_2(g)$	+	C(graphite)	$\rightleftharpoons$	$2CO(g)$
Initial	0.458		—		0
Change	$-x$		—		$+2x$
Equilibrium	$0.458 - x$		—		$2x$

We treat each column like a list of numbers to add together: *the initial quantity plus the change in that quantity gives the equilibrium quantity*. Note that we *only* consider substances whose concentrations change; thus, the column for C(graphite) is blank.

To solve for  $K_p$ , we substitute equilibrium values into  $Q_p$ , so we first have to find  $x$ . To do this, we use the other piece of data given,  $P_{\text{total}(\text{eq})}$ . According to Dalton's law of partial pressures and using the equilibrium quantities from the reaction table,

$$P_{\text{total}(\text{eq})} = 0.757 \text{ atm} = P_{CO_2(\text{eq})} + P_{CO(\text{eq})} = (0.458 \text{ atm} - x) + 2x$$

Thus,

$$0.757 \text{ atm} = 0.458 \text{ atm} + x \quad \text{and} \quad x = 0.299 \text{ atm}$$

With  $x$  known, we determine the equilibrium partial pressures:

$$P_{\text{CO}_2(\text{eq})} = 0.458 \text{ atm} - x = 0.458 \text{ atm} - 0.299 \text{ atm} = 0.159 \text{ atm}$$

$$P_{\text{CO}(\text{eq})} = 2x = 2(0.299 \text{ atm}) = 0.598 \text{ atm}$$

Then we substitute them into  $Q_p$  to find  $K_p$ :

$$Q_p = \frac{P_{\text{CO}(\text{eq})}^2}{P_{\text{CO}_2(\text{eq})}} = \frac{(0.598)^2}{0.159} = 2.25 = K_p$$

(From now on, the subscripts “init” and “eq” appear only when it is not clear whether a quantity is an initial or equilibrium value.)

Student data indicate that you may struggle with constructing a reaction table in equilibrium calculations. Access the Smartbook to view additional Learning Resources on this topic.

#### SAMPLE PROBLEM 17.6

#### Calculating $K_c$ from Concentration Data

**Problem** In order to study hydrogen halide decomposition, a researcher fills an evacuated 2.00-L flask with 0.200 mol of HI gas and allows the reaction to proceed at 453°C:

At equilibrium,  $[\text{HI}] = 0.078 \text{ M}$ . Calculate  $K_c$ .

**Plan** To calculate  $K_c$ , we need the equilibrium concentrations. We can find the initial  $[\text{HI}]$  from the amount (0.200 mol) and the flask volume (2.00 L), and we are given  $[\text{HI}]$  at equilibrium (0.078 M). From the balanced equation, when  $2x$  mol of HI reacts,  $x$  mol of  $\text{H}_2$  and  $x$  mol of  $\text{I}_2$  form. We set up a reaction table, use the known  $[\text{HI}]$  at equilibrium to solve for  $x$  (the change in  $[\text{H}_2]$  or  $[\text{I}_2]$ ), and substitute the concentrations into  $Q_c$ .

**Solution** Calculating initial  $[\text{HI}]$ :

$$[\text{HI}] = \frac{0.200 \text{ mol}}{2.00 \text{ L}} = 0.100 \text{ M}$$

Setting up the reaction table, with  $x = [\text{H}_2]$  or  $[\text{I}_2]$  that forms and  $2x = [\text{HI}]$  that reacts:

Concentration (M)	2HI(g)	$\rightleftharpoons$	H <sub>2</sub> (g)	+	I <sub>2</sub> (g)
Initial	0.100		0		0
Change	-2x		+x		+x
Equilibrium	0.100 - 2x		x		x

Solving for  $x$ , using the known  $[\text{HI}]$  at equilibrium:

$$[\text{HI}] = 0.100 \text{ M} - 2x = 0.078 \text{ M} \quad \text{so} \quad x = 0.011 \text{ M}$$

Therefore, the equilibrium concentrations are

$$[\text{H}_2] = [\text{I}_2] = 0.011 \text{ M} \quad \text{and we were given} \quad [\text{HI}] = 0.078 \text{ M}$$

Substituting into the reaction quotient:

$$Q_c = \frac{[\text{H}_2][\text{I}_2]}{[\text{HI}]^2}$$

$$\text{Thus,} \quad K_c = \frac{(0.011)(0.011)}{0.078^2} = 0.020$$

**Check** Rounding gives  $\sim 0.01^2/0.08^2 = 0.02$ . Because the initial  $[\text{HI}]$  of 0.100 M fell slightly at equilibrium to 0.078 M, relatively little product formed; so we expect  $K_c < 1$ .

#### FOLLOW-UP PROBLEMS

**17.6A** The atmospheric oxidation of nitrogen monoxide,  $2\text{NO}(g) + \text{O}_2(g) \rightleftharpoons 2\text{NO}_2(g)$ , was studied at 184°C with initial pressures of 1.000 atm of NO and 1.000 atm of  $\text{O}_2$ . At equilibrium,  $P_{\text{O}_2} = 0.506 \text{ atm}$ . Calculate  $K_p$ .

**17.6B** To study the reaction between ammonia and oxygen,

a flask was filled with 2.40 M  $\text{NH}_3$  and 2.40 M  $\text{O}_2$  at a particular temperature; the reaction proceeded, and at equilibrium  $[\text{N}_2\text{O}_4] = 0.134 \text{ M}$ . Calculate  $K_c$ .

**SOME SIMILAR PROBLEMS** 17.52, 17.53, 17.55, and 17.56

## Using the Equilibrium Constant to Find Quantities

The type of problem that involves finding equilibrium quantities also has several variations. Sample Problem 17.7 is one variation, in which we know  $K$  and some of the equilibrium concentrations and must find another equilibrium concentration.

### SAMPLE PROBLEM 17.7

#### Determining Equilibrium Concentrations from $K_c$

**Problem** In a study of the conversion of methane to other fuels, a chemical engineer mixes gaseous  $\text{CH}_4$  and  $\text{H}_2\text{O}$  in a 0.32-L flask at 1200 K. At equilibrium, the flask contains 0.028 mol of  $\text{CO}$ , 0.084 mol of  $\text{H}_2$ , and 0.045 mol of  $\text{CH}_4$ . What is  $[\text{H}_2\text{O}]$  at equilibrium ( $K_c = 0.26$  for this process at 1200 K)?

**Plan** First, we write the balanced equation and the reaction quotient. We calculate the equilibrium concentrations from the given numbers of moles and the flask volume (0.32 L). Substituting these concentrations into  $Q_c$  and setting its value equal to the given  $K_c$  (0.26), we solve for the unknown equilibrium concentration,  $[\text{H}_2\text{O}]$ .

**Solution** Writing the balanced equation and reaction quotient:

Determining the equilibrium concentrations:

$$[\text{CH}_4] = \frac{0.045 \text{ mol}}{0.32 \text{ L}} = 0.14 \text{ M}$$

Similarly,  $[\text{CO}] = 0.088 \text{ M}$  and  $[\text{H}_2] = 0.26 \text{ M}$ .

Calculating  $[\text{H}_2\text{O}]$  at equilibrium: Since  $Q_c = K_c$ , rearranging gives

$$[\text{H}_2\text{O}] = \frac{[\text{CO}][\text{H}_2]^3}{[\text{CH}_4] K_c} = \frac{(0.088)(0.26)^3}{(0.14)(0.26)} = 0.042 \text{ M}$$

**Check** Always check by substituting the concentrations into  $Q_c$  to confirm that the result is equal to  $K_c$ :

$$Q_c = \frac{[\text{CO}][\text{H}_2]^3}{[\text{CH}_4][\text{H}_2\text{O}]} = \frac{(0.088)(0.26)^3}{(0.14)(0.042)} = 0.26 = K_c$$

### FOLLOW-UP PROBLEMS

**17.7A** Nitrogen monoxide decomposes by the following equation:  
 $2\text{NO}(g) \rightleftharpoons \text{N}_2(g) + \text{O}_2(g)$ ;  $K_c = 2.3 \times 10^{30}$  at 298 K. In the atmosphere,  $P_{\text{O}_2} = 0.209 \text{ atm}$  and  $P_{\text{N}_2} = 0.781 \text{ atm}$ . What is the equilibrium partial pressure of  $\text{NO}$  in the air we breathe? (*Hint*: You need  $K_p$  to find the partial pressure.)

**17.7B** Phosphine decomposes by the following equation:

In a reaction mixture at equilibrium,  $P_{\text{PH}_3} = 0.112 \text{ atm}$  and  $P_{\text{P}_2} = 0.215 \text{ atm}$ . What is the equilibrium partial pressure of  $\text{H}_2$ ?

**SOME SIMILAR PROBLEMS** 17.46 and 17.47

In a somewhat more involved variation, we know  $K$  and *initial* quantities and must find *equilibrium* quantities, for which we use a reaction table. Sample Problem 17.8 focuses on this type of situation.

### SAMPLE PROBLEM 17.8

#### Determining Equilibrium Concentrations from Initial Concentrations and $K_c$

**Problem** Fuel engineers use the extent of the change from  $\text{CO}$  and  $\text{H}_2\text{O}$  to  $\text{CO}_2$  and  $\text{H}_2$  to regulate the proportions of synthetic fuel mixtures. If 0.250 mol of  $\text{CO}$  gas and 0.250 mol of  $\text{H}_2\text{O}$  gas are placed in a 125-mL flask at 900 K, what is the composition of the equilibrium mixture? At this temperature,  $K_c$  is 1.56.

**Plan** We have to find the “composition” of the equilibrium mixture, in other words, the equilibrium concentrations. As always, we write the balanced equation and use it to write the reaction quotient. We find the initial  $[\text{CO}]$  and  $[\text{H}_2\text{O}]$  from the amounts (0.250 mol of each) and volume (0.125 L), use the balanced equation to define  $x$  and set up a reaction table, substitute into  $Q_c$ , and solve for  $x$ , from which we calculate the concentrations.

**Solution** Writing the balanced equation and reaction quotient:

Calculating initial reactant concentrations:

$$[\text{CO}] = [\text{H}_2\text{O}] = \frac{0.250 \text{ mol}}{0.125 \text{ L}} = 2.00 \text{ M}$$

Setting up the reaction table, with  $x = [\text{CO}]$  and  $[\text{H}_2\text{O}]$  that react (note the 1/1 molar ratio among all reactants and products):

Concentration (M)	CO(g)	+	H <sub>2</sub> O(g)	⇌	CO <sub>2</sub> (g)	+	H <sub>2</sub> (g)
Initial	2.00		2.00		0		0
Change	-x		-x		+x		+x
Equilibrium	2.00 - x		2.00 - x		x		x

Substituting into the reaction quotient and solving for  $x$ :

$$Q_c = \frac{[\text{CO}_2][\text{H}_2]}{[\text{CO}][\text{H}_2\text{O}]} = \frac{(x)(x)}{(2.00 - x)(2.00 - x)} = \frac{x^2}{(2.00 - x)^2}$$

At equilibrium, we have

$$Q_c = K_c = 1.56 = \frac{x^2}{(2.00 - x)^2}$$

We can apply the following math shortcut in this case *but not in general*: Because the right side of the preceding equation is a perfect square, we take the square root of both sides:

$$\sqrt{1.56} = \frac{x}{2.00 - x} = \pm 1.25$$

A positive number (1.56) has a positive *and* a negative root, but in this case, only the positive root has any chemical meaning, so we ignore the negative root:\*

$$1.25 = \frac{x}{2.00 - x} \quad \text{or} \quad 2.50 - 1.25x = x$$

$$\text{So} \quad 2.50 = 2.25x \quad \text{therefore} \quad x = 1.11 \text{ M}$$

Calculating equilibrium concentrations:

$$\begin{aligned} [\text{CO}] = [\text{H}_2\text{O}] &= 2.00 \text{ M} - x = 2.00 \text{ M} - 1.11 \text{ M} = 0.89 \text{ M} \\ [\text{CO}_2] = [\text{H}_2] &= x = 1.11 \text{ M} \end{aligned}$$

**Check** Given the intermediate size of  $K_c$  (1.56), it makes sense that the changes in concentration are moderate. It's a good idea to check that the sign of  $x$  in the reaction table is correct—only reactants were initially present, so  $x$  has a negative sign for reactants and a positive sign for products. Also check that the equilibrium concentrations give the known  $K_c$ :  $\frac{(1.11)(1.11)}{(0.89)(0.89)} = 1.56$ .

\*The negative root gives  $-1.25 = \frac{x}{2.00 - x}$ , or  $-2.50 + 1.25x = x$ .

$$\text{So} \quad 2.50 = 0.25x \quad \text{and} \quad x = 10. \text{ M}$$

This value has no chemical meaning because we started with 2.00 M as the concentration of each reactant, so it is impossible for  $x$  to be 10. M. Moreover, the square root of an equilibrium constant is another equilibrium constant, which cannot have a negative value.

## FOLLOW-UP PROBLEMS

**17.8A** The decomposition of HI at low temperature was studied by injecting 2.50 mol of HI into a 10.32-L vessel at 25°C. What is  $[H_2]$  at equilibrium for the reaction  $2HI(g) \rightleftharpoons H_2(g) + I_2(g)$ ;  $K_c = 1.26 \times 10^{-3}$ ?

**17.8B** The following reaction has a  $K_c$  value of 0.18 at 500. K:

If 6.15 mol of  $Cl_2O$  gas and 6.15 mol of  $H_2O$  gas are added to a 5.00-L flask at 500. K, calculate the equilibrium concentrations of  $Cl_2O$ ,  $H_2O$ , and  $HOCl$ .

**SOME SIMILAR PROBLEMS** 17.48, 17.54, and 17.57

**Using the Quadratic Formula to Find the Unknown** The shortcut we used to simplify the math in Sample Problem 17.8 is a special case that occurred because we started with equal concentrations of the reactants, but typically, we start with different concentrations of reactants. Suppose, for example, we start with 2.00 M CO and 1.00 M  $H_2O$ . Now, the reaction table becomes

Concentration (M)	CO(g)	+	H <sub>2</sub> O(g)	⇌	CO <sub>2</sub> (g)	+	H <sub>2</sub> (g)
Initial	2.00		1.00		0		0
Change	-x		-x		+x		+x
Equilibrium	2.00 - x		1.00 - x		x		x

Substituting these values into  $Q_c$ , we obtain

$$Q_c = \frac{[CO_2][H_2]}{[CO][H_2O]} = \frac{(x)(x)}{(2.00 - x)(1.00 - x)} = \frac{x^2}{x^2 - 3.00x + 2.00}$$

At equilibrium, using the value of  $K_c$  from Sample Problem 17.8, we have

$$1.56 = \frac{x^2}{x^2 - 3.00x + 2.00}$$

To solve for  $x$  in this case, we rearrange the previous expression into the form of a quadratic equation:

$$a x^2 + b x + c = 0$$

$$0.56x^2 - 4.68x + 3.12 = 0$$

where  $a = 0.56$ ,  $b = -4.68$ , and  $c = 3.12$ . Then we find  $x$  with the quadratic formula (Appendix A):

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

The  $\pm$  sign means that we obtain two possible values for  $x$ :

$$x = \frac{4.68 \pm \sqrt{(-4.68)^2 - 4(0.56)(3.12)}}{2(0.56)}$$

$$x = 7.6 \text{ M} \quad \text{and} \quad x = 0.73 \text{ M}$$

But only one of the values makes sense chemically. In this case, addition of the square root term gave the larger value, which would yield negative concentrations at equilibrium (for example,  $2.00 \text{ M} - 7.6 \text{ M} = -5.6 \text{ M}$ ); these have no meaning. Therefore,  $x = 0.73 \text{ M}$ , and we have

$$[CO] = 2.00 \text{ M} - x = 2.00 \text{ M} - 0.73 \text{ M} = 1.27 \text{ M}$$

$$[H_2O] = 1.00 \text{ M} - x = 0.27 \text{ M}$$

$$[CO_2] = [H_2] = x = 0.73 \text{ M}$$

Checking to see if these values give the known  $K_c$ , we have

$$K_c = \frac{(0.73)(0.73)}{(1.27)(0.27)} = 1.6 \text{ (within rounding of 1.56)}$$

**A Simplifying Assumption for Finding the Unknown** In many cases, we can use chemical “common sense” to make an assumption that simplifies the math by avoiding the need to use the quadratic formula to find  $x$ . In general,

- if a reaction has a relatively small  $K$  and a relatively large initial reactant concentration, the concentration change ( $x$ ) can often be neglected.

This assumption does not mean that  $x = 0$ , because then there would be no reaction. It means that if a reaction starts with a high  $[\text{reactant}]_{\text{init}}$  and proceeds very little to reach equilibrium (small  $K$ ), the reactant concentration at equilibrium,  $[\text{reactant}]_{\text{eq}}$ , will be nearly the same as  $[\text{reactant}]_{\text{init}}$ .

Here’s an everyday analogy for this assumption. On a bathroom scale, you weigh 158 lb. Take off your wristwatch, and you still weigh 158 lb. Within the accuracy of the scale, the weight of the watch is so small compared with your body weight that it can be neglected:

$$\text{Initial body weight} - \text{weight of watch} = \text{final body weight} \approx \text{initial body weight}$$

Thus, let’s say the initial concentration of A is 0.500  $M$  and, because of a small  $K_c$ , the concentration of A that reacts is 0.002  $M$ . We can then assume that

$$0.500\ M - 0.002\ M = 0.498\ M \approx 0.500\ M$$

that is,

$$[\text{A}]_{\text{init}} - [\text{A}]_{\text{reacting}} = [\text{A}]_{\text{eq}} \approx [\text{A}]_{\text{init}} \quad (17.9)$$

To justify the assumption that  $x$  is negligible, we make sure the error introduced is not significant. One common criterion for “significant” is the 5% rule:

- if the assumption results in a change that is less than 5% of the initial concentration, the error is not significant, and the assumption is justified.

Let’s see how making this assumption simplifies the math and if it is justified in the cases of two different  $[\text{reactant}]_{\text{init}}$  values.

### Student Hot Spot

Student data indicate that you may struggle with applying the simplifying assumption in equilibrium problems. Access the Smartbook to view additional Learning Resources on this topic.

### SAMPLE PROBLEM 17.9

### Making a Simplifying Assumption to Calculate Equilibrium Concentrations

**Problem** Phosgene is a potent chemical warfare agent that is now outlawed by international agreement. It decomposes by the reaction

Calculate  $[\text{CO}]$ ,  $[\text{Cl}_2]$ , and  $[\text{COCl}_2]$  when each of the following amounts of phosgene decomposes and reaches equilibrium in a 10.0-L flask:

- (a) 5.00 mol of  $\text{COCl}_2$       (b) 0.100 mol of  $\text{COCl}_2$

**Plan** We know from the balanced equation that when  $x$  mol of  $\text{COCl}_2$  decomposes,  $x$  mol of  $\text{CO}$  and  $x$  mol of  $\text{Cl}_2$  form. We use the volume (10.0 L) to convert amount (5.00 mol or 0.100 mol) to molar concentration, define  $x$  and set up the reaction table, and substitute the values into  $Q_c$ . Before using the quadratic formula, we assume that  $x$  is negligibly small. After solving for  $x$ , we check the assumption and find the equilibrium concentrations. If the assumption is not justified, we use the quadratic formula to find  $x$ .

**Solution** (a) For 5.00 mol of  $\text{COCl}_2$ . Writing the reaction quotient:

$$Q_c = \frac{[\text{CO}][\text{Cl}_2]}{[\text{COCl}_2]}$$

Calculating the initial reactant concentration,  $[\text{COCl}_2]_{\text{init}}$ :

$$[\text{COCl}_2]_{\text{init}} = \frac{5.00\ \text{mol}}{10.0\ \text{L}} = 0.500\ M$$

Setting up the reaction table, with  $x$  equal to  $[\text{COCl}_2]_{\text{reacting}}$ :

Concentration (M)	$\text{COCl}_2(\text{g})$	$\rightleftharpoons$	$\text{CO}(\text{g})$	+	$\text{Cl}_2(\text{g})$
Initial	0.500		0		0
Change	$-x$		$+x$		$+x$
Equilibrium	$0.500 - x$		$x$		$x$

If we use the equilibrium values in  $Q_c$  with the given  $K_c$ , we obtain

$$Q_c = \frac{[\text{CO}][\text{Cl}_2]}{[\text{COCl}_2]} = \frac{x^2}{0.500 - x} = K_c = 8.3 \times 10^{-4}$$

Because  $K_c$  is small, the reaction does not proceed very far to the right, so let's assume that  $x$  ( $[\text{COCl}_2]_{\text{reacting}}$ ) can be neglected. In other words, we assume that the equilibrium concentration is nearly the same as the initial concentration, 0.500 M:

$$[\text{COCl}_2]_{\text{init}} - [\text{COCl}_2]_{\text{reacting}} = [\text{COCl}_2]_{\text{eq}}$$

$$0.500 \text{ M} - x \approx 0.500 \text{ M}$$

Using this assumption, we substitute and solve for  $x$ :

$$K_c = 8.3 \times 10^{-4} \approx \frac{x^2}{0.500}$$

$$x^2 \approx (8.3 \times 10^{-4})(0.500) \quad \text{so} \quad x \approx 2.0 \times 10^{-2}$$

Checking the assumption by seeing if the error is  $<5\%$ :

$$\frac{[\text{Change}]}{[\text{Initial}]} \times 100 = \frac{2.0 \times 10^{-2}}{0.500} \times 100 = 4\% (<5\%, \text{ so the assumption is justified})$$

Solving for the equilibrium concentrations:

$$[\text{CO}] = [\text{Cl}_2] = x = 2.0 \times 10^{-2} \text{ M}$$

$$[\text{COCl}_2] = 0.500 \text{ M} - x = 0.480 \text{ M}$$

(b) For 0.100 mol of  $\text{COCl}_2$ . The calculation in this case is the same as the calculation in part (a), except that  $[\text{COCl}_2]_{\text{init}} = 0.100 \text{ mol}/10.0 \text{ L} = 0.0100 \text{ M}$ . Thus, at equilibrium,

$$Q_c = \frac{[\text{CO}][\text{Cl}_2]}{[\text{COCl}_2]} = \frac{x^2}{0.0100 - x} = K_c = 8.3 \times 10^{-4}$$

Making the assumption that  $0.0100 \text{ M} - x \approx 0.0100 \text{ M}$  and solving for  $x$ :

$$K_c = 8.3 \times 10^{-4} \approx \frac{x^2}{0.0100} \quad \text{so} \quad x \approx 2.9 \times 10^{-3}$$

Checking the assumption:

$$\frac{2.9 \times 10^{-3}}{0.0100} \times 100 = 29\% (>5\%, \text{ so the assumption is not justified})$$

Rearranging  $Q_c$  and its value at equilibrium into the form of a quadratic equation gives

$$8.3 \times 10^{-4} = \frac{x^2}{0.0100 - x} \quad \text{or} \quad x^2 = (8.3 \times 10^{-6}) - (8.3 \times 10^{-4})x$$

and so

$$x^2 + (8.3 \times 10^{-4})x - (8.3 \times 10^{-6}) = 0$$

Solving this equation with the quadratic formula shows that

$$x = \frac{-8.3 \times 10^{-4} \pm \sqrt{(8.3 \times 10^{-4})^2 - 4(1)(-8.3 \times 10^{-6})}}{2(1)}$$

The only meaningful value of  $x$  is  $2.5 \times 10^{-3}$ .

Solving for the equilibrium concentrations:

$$[\text{CO}] = [\text{Cl}_2] = x = 2.5 \times 10^{-3} \text{ M}$$

$$[\text{COCl}_2] = 1.00 \times 10^{-2} \text{ M} - x = 7.5 \times 10^{-3} \text{ M}$$

**Check** Once again, use the calculated values to be sure you obtain the given  $K_c$ .

**Comment** The main point is that the simplifying assumption was justified at the high  $[\text{COCl}_2]_{\text{init}}$  in part (a) but *not* at the low  $[\text{COCl}_2]_{\text{init}}$  in part (b). The amount of  $[\text{COCl}_2]_{\text{reacting}}$

is small in (b), but since  $[\text{COCl}_2]_{\text{init}}$  is also small,  $[\text{COCl}_2]_{\text{reacting}}$  is a high percentage of  $[\text{COCl}_2]_{\text{init}}$  and cannot be neglected without introducing significant error.

### FOLLOW-UP PROBLEMS

**17.9A** In a study of the effect of temperature on halogen decomposition, 0.50 mol of  $\text{I}_2$  was heated in a 2.5-L vessel, and the following reaction occurred:  $\text{I}_2(\text{g}) \rightleftharpoons 2\text{I}(\text{g})$

(a) Calculate  $[\text{I}_2]$  and  $[\text{I}]$  at equilibrium at 600 K;  $K_c = 2.94 \times 10^{-10}$ .

(b) Calculate  $[\text{I}_2]$  and  $[\text{I}]$  at equilibrium at 2000 K;  $K_c = 0.209$ .

**17.9B** Phosphorus pentachloride decomposes as follows:

Calculate the equilibrium partial pressure of  $\text{PCl}_5$  if the reaction begins with:

(a) a  $\text{PCl}_5$  partial pressure of 0.18 atm;

(b) a  $\text{PCl}_5$  partial pressure of 0.025 atm.

**SOME SIMILAR PROBLEMS** 17.49–17.51

**Predicting When the Assumption Will Be Justified** To summarize, we assume that  $x$  ( $[\text{A}]_{\text{reacting}}$ ) can be neglected if  $K_c$  is relatively small and/or  $[\text{A}]_{\text{init}}$  is relatively large. The same holds for  $K_p$  and  $P_{\text{A}(\text{init})}$ . But *how* small or large must these variables be? Here's a benchmark for deciding when to make the assumption:

- If  $\frac{[\text{A}]_{\text{init}}}{K_c} > 400$ , the assumption is justified: neglecting  $x$  introduces an error  $< 5\%$ .
- If  $\frac{[\text{A}]_{\text{init}}}{K_c} < 400$ , the assumption is *not* justified; neglecting  $x$  introduces an error  $> 5\%$ , so we solve a quadratic equation to find  $x$ .

For example, using the values from Sample Problem 17.9, we have

Part (a): For  $[\text{A}]_{\text{init}} = 0.500 \text{ M}$ ,  $\frac{0.500}{8.3 \times 10^{-4}} = 6.0 \times 10^2$ , which is greater than 400.

Part (b): For  $[\text{A}]_{\text{init}} = 0.0100 \text{ M}$ ,  $\frac{0.0100}{8.3 \times 10^{-4}} = 12$ , which is less than 400.

We will make a similar assumption in many problems in Chapters 18 and 19.

## Problems Involving Mixtures of Reactants and Products

In the problems so far, the reaction *had* to go toward products because it started with only reactants. And therefore, in the reaction tables, we knew that the unknown change in reactant concentration had a negative sign ( $-x$ ) and the change in product concentration had a positive sign ( $+x$ ). If, however, we start with a *mixture* of reactants and products, the reaction direction is not obvious. In those cases, we apply the idea from Section 17.4 and first *compare the values of  $Q$  and  $K$  to find the direction in which the reaction is proceeding to reach equilibrium*. (To focus on this idea, Sample Problem 17.10 uses concentrations that avoid the need for the quadratic formula.)

### SAMPLE PROBLEM 17.10

### Predicting Reaction Direction and Calculating Equilibrium Concentrations

**Problem** The research and development unit of a chemical company is studying the reaction of  $\text{CH}_4$  and  $\text{H}_2\text{S}$ , two components of natural gas:

In one experiment, 1.00 mol of  $\text{CH}_4$ , 1.00 mol of  $\text{CS}_2$ , 2.00 mol of  $\text{H}_2\text{S}$ , and 2.00 mol of  $\text{H}_2$  are mixed in a 250.-mL vessel at  $960^\circ\text{C}$ . At this temperature,  $K_c = 0.036$ .

(a) In which direction will the reaction proceed to reach equilibrium?

(b) If  $[\text{CH}_4] = 5.56 \text{ M}$  at equilibrium, what are the equilibrium concentrations of the other substances?

**Plan (a)** To find the direction, we convert the given initial amounts and volume (0.250 L) to concentrations, calculate  $Q_c$ , and compare it with  $K_c$ . **(b)** Based on this information, we determine the sign of each concentration change for the reaction table and then use the known  $[\text{CH}_4]$  at equilibrium (5.56 M) to determine  $x$  and the other equilibrium concentrations.

**Solution (a)** Calculating the initial concentrations:

$$[\text{CH}_4] = \frac{1.00 \text{ mol}}{0.250 \text{ L}} = 4.00 \text{ M}$$

Similarly,  $[\text{H}_2\text{S}] = 8.00 \text{ M}$ ,  $[\text{CS}_2] = 4.00 \text{ M}$ , and  $[\text{H}_2] = 8.00 \text{ M}$ .

Calculating the value of  $Q_c$ :

$$Q_c = \frac{[\text{CS}_2][\text{H}_2]^4}{[\text{CH}_4][\text{H}_2\text{S}]^2} = \frac{(4.00)(8.00)^4}{(4.00)(8.00)^2} = 64.0$$

Comparing  $Q_c$  and  $K_c$ :  $Q_c > K_c$  ( $64.0 > 0.036$ ), so the reaction proceeds to the left. Therefore, concentrations of reactants increase (+ $x$ ) and those of products decrease (− $x$ ).

**(b)** Setting up a reaction table, with  $x = [\text{CS}_2]$  that reacts, which equals  $[\text{CH}_4]$  that forms:

Concentration (M)	$\text{CH}_4(\text{g})$	+	$2\text{H}_2\text{S}(\text{g})$	$\rightleftharpoons$	$\text{CS}_2(\text{g})$	+	$4\text{H}_2(\text{g})$
Initial	4.00		8.00		4.00		8.00
Change	+ $x$		+2 $x$		− $x$		−4 $x$
Equilibrium	$4.00 + x$		$8.00 + 2x$		$4.00 - x$		$8.00 - 4x$

Solving for  $x$ : At equilibrium,

$$[\text{CH}_4] = 5.56 \text{ M} = 4.00 \text{ M} + x \quad \text{so} \quad x = 1.56 \text{ M}$$

$$\text{Thus, } [\text{H}_2\text{S}] = 8.00 \text{ M} + 2x = 8.00 \text{ M} + 2(1.56 \text{ M}) = 11.12 \text{ M}$$

$$[\text{CS}_2] = 4.00 \text{ M} - x = 4.00 \text{ M} - 1.56 \text{ M} = 2.44 \text{ M}$$

$$[\text{H}_2] = 8.00 \text{ M} - 4x = 8.00 \text{ M} - 4(1.56 \text{ M}) = 1.76 \text{ M}$$

**Check** The comparison of  $Q_c$  and  $K_c$  showed the reaction proceeding to the left. The given data from part (b) confirm this because  $[\text{CH}_4]$  increases from 4.00 M to 5.56 M during the reaction. As always, you should check that the concentrations give the known  $K_c$ :

$$\frac{(2.44)(1.76)^4}{(5.56)(11.12)^2} = 0.0341, \text{ which is close to } 0.036$$

### FOLLOW-UP PROBLEMS

**17.10A** An inorganic chemist studying the reactions of phosphorus halides mixes 0.1050 mol of  $\text{PCl}_5$  with 0.0450 mol of  $\text{Cl}_2$  and 0.0450 mol of  $\text{PCl}_3$  in a 0.5000-L flask at 250°C:

**(a)** In which direction will the reaction proceed?

**(b)** If  $[\text{PCl}_5] = 0.2065 \text{ M}$  at equilibrium, what are the equilibrium concentrations of the other components?

**17.10B** A chemist studying the production of nitrogen monoxide (NO) in the atmosphere adds 0.500 atm of  $\text{N}_2$ , 0.500 atm of  $\text{O}_2$ , and 0.750 atm of NO to a sealed container at 2500°C:

Determine the direction in which the reaction proceeds, and calculate the equilibrium pressures of all three gases.

**SOME SIMILAR PROBLEMS** 17.94 and 17.102

Figure 17.6 on the next page groups the steps for solving equilibrium problems in which you know  $K$  and some initial quantities and must find the equilibrium quantities.

**SOLVING EQUILIBRIUM PROBLEMS**

**PRELIMINARY SETTING UP**

- Write the balanced equation.
- Write the reaction quotient,  $Q$ .
- Convert all amounts into the correct units ( $M$  or  $\text{atm}$ ).

**WORKING ON THE REACTION TABLE**

- When reaction direction is not known, compare  $Q$  with  $K$ .
- Construct a reaction table.

✓ Check the sign of  $x$ , the change in the concentration (or pressure).

**SOLVING FOR  $x$  AND EQUILIBRIUM QUANTITIES**

- Substitute the quantities into  $Q$ .
- To simplify the math, assume that  $x$  is negligible:  
 $([A]_{\text{init}} - x) \approx [A]_{\text{eq}} \approx [A]_{\text{init}}$
- Solve for  $x$ .

✓ Check that assumption is justified (<5% error). If not, solve quadratic equation for  $x$ .

- Find the equilibrium quantities.

✓ Check to see that calculated values give the known  $K$ .

**Figure 17.6** Steps in solving equilibrium problems.

Le Châtelier's principle applies to many systems.

## › Summary of Section 17.5

- › In equilibrium problems, we typically use quantities (concentrations or pressures) of reactants and products to find  $K$ , or we use  $K$  to find quantities.
- › Reaction tables summarize the initial quantities, their changes during the reaction, and the equilibrium quantities.
- › To simplify calculations, we assume that if  $K$  is small and the initial quantity of reactant is large, the unknown change in reactant ( $x$ ) can be neglected. If this assumption is not justified (that is, if the resulting error is greater than 5%), we use the quadratic formula to find  $x$ .
- › For reactions that start with a mixture of reactants and products, we first determine reaction direction by comparing  $Q$  and  $K$  to decide on the sign of  $x$ .

## 17.6 REACTION CONDITIONS AND EQUILIBRIUM: LE CHÂTELIER'S PRINCIPLE

Change conditions so that a system is no longer at equilibrium, and it has the remarkable ability to adjust itself and reattain equilibrium. This phenomenon is described by **Le Châtelier's principle**: when a chemical system at equilibrium is disturbed, it reattains equilibrium by undergoing a net reaction that reduces the effect of the disturbance.

Two phrases in this statement *need* further explanation:

1. How is a system “disturbed”? At equilibrium,  $Q$  equals  $K$ . The system is disturbed when a change in conditions forces it temporarily out of equilibrium ( $Q \neq K$ ). Three common disturbances are a change in concentration, a change in pressure (caused by a change in volume), or a change in temperature. We'll discuss each below.

2. What does a “net reaction” mean? This phrase refers to a shift in the *equilibrium position* to the right or left. The *equilibrium position* is defined by the specific equilibrium concentrations (or pressures). *Concentrations (or pressures) change in a way that reduces the effect of the change in conditions, and the system attains a new equilibrium position:*

- a shift to the right is a net reaction that converts reactant to product until equilibrium is reattained;
- a shift to the left is a net reaction that converts product to reactant until equilibrium is reattained.

For the remainder of this section, we'll examine a system at equilibrium to see how it responds to changes in concentration, pressure (volume), or temperature; then, we'll see what happens when we add a catalyst. As our example, we use the gaseous reaction between phosphorus trichloride and chlorine to produce phosphorus pentachloride:

Le Châtelier's principle holds for many systems at equilibrium in both the natural and social sciences—the effects of disease or drought on populations of predators and prey on the African savanna (*see photo*), a change in the cost of petroleum based on a balance of supply and demand, and even the formation of certain elements in the core of a star.

### The Effect of a Change in Concentration

When a system at equilibrium is disturbed by a change in concentration of one of the components, it reacts in the direction that reduces the change:

- If the concentration of A is increased, the system reacts to consume some of that component.
- If the concentration of A is decreased, the system reacts to produce some of it.

Only components that appear in  $Q$  can have an effect, so changes in the amounts of pure liquids and solids cannot.

**A Qualitative View of a Concentration Change** At 523 K, the  $\text{PCl}_3\text{-Cl}_2\text{-PCl}_5$  system reaches equilibrium when

Starting with  $Q_c$  equal to  $K_c$ , let's think through some changes in concentration:

1. *Adding a reactant.* What happens if we disturb the system by adding some  $\text{Cl}_2$  gas? To reduce this disturbance, the system will consume some of the added  $\text{Cl}_2$  by shifting toward product. With regard to the reaction quotient, when the  $[\text{Cl}_2]$  term increases, the value of  $Q_c$  decreases; thus,  $Q_c < K_c$ . As some of the added  $\text{Cl}_2$  reacts with some of the  $\text{PCl}_3$  to form more  $\text{PCl}_5$ , the denominator becomes smaller again and the numerator larger, until eventually  $Q_c = K_c$  again. Notice the changes in the new equilibrium concentrations:  $[\text{Cl}_2]$  and  $[\text{PCl}_5]$  are higher than in the original equilibrium position, and  $[\text{PCl}_3]$  is lower. Nevertheless, the ratio of values gives the same  $K_c$ . Thus, *the equilibrium position shifts to the right when a component on the left is added:*

2. *Removing a reactant.* What happens if we disturb the system by removing some  $\text{PCl}_3$ ? To reduce this disturbance, the system will replace the  $\text{PCl}_3$  by consuming some  $\text{PCl}_5$  and proceeding toward reactants. With regard to  $Q_c$ , when the  $[\text{PCl}_3]$  term decreases,  $Q_c$  increases, so  $Q_c > K_c$ . As some  $\text{PCl}_5$  decomposes to  $\text{PCl}_3$  and  $\text{Cl}_2$ , the numerator decreases and the denominator increases until  $Q_c = K_c$  again. Once again, the new and old equilibrium concentrations are different, but the value of  $K_c$  is not. Thus, *the equilibrium position shifts to the left when a component on the left is removed:*

3. *Adding or removing a product.* The same points we just made for a reactant hold for a product. If we add  $\text{PCl}_5$ , the equilibrium position shifts to the left to consume  $\text{PCl}_5$ ; if we remove some  $\text{PCl}_5$ , the equilibrium position shifts to the right to produce  $\text{PCl}_5$ .

In other words, no matter how the disturbance in concentration comes about, *the system reacts to consume some of the added substance or produce some of the removed substance to make  $Q_c = K_c$  again* (Figure 17.7):

- The equilibrium position shifts to the *right* if a reactant is added or a product is removed: [reactant] increases or [product] decreases.
- The equilibrium position shifts to the *left* if a reactant is removed or a product is added: [reactant] decreases or [product] increases.

**Figure 17.7** The effect of a change in concentration on a system at equilibrium.

**A Quantitative View of a Concentration Change** As you saw, the system “reduces the effect of the disturbance.” But the effect is not completely eliminated, as we can see from a quantitative comparison of original and new equilibrium positions.

Consider what happens when we add  $\text{Cl}_2$  to a system whose original equilibrium position was established with  $[\text{PCl}_3] = 0.200 \text{ M}$ ,  $[\text{Cl}_2] = 0.125 \text{ M}$ , and  $[\text{PCl}_5] = 0.600 \text{ M}$ . That is,

$$Q_c = \frac{[\text{PCl}_5]}{[\text{PCl}_3][\text{Cl}_2]} = \frac{0.600}{(0.200)(0.125)} = 24.0 = K_c$$

Table 17.3

The Effect of Added  $\text{Cl}_2$  on the  $\text{PCl}_3\text{-Cl}_2\text{-PCl}_5$  System

Concentration (M)	$\text{PCl}_3(\text{g})$	+	$\text{Cl}_2(\text{g})$	$\rightleftharpoons$	$\text{PCl}_5(\text{g})$
Original equilibrium	0.200		0.125		0.600
Disturbance			+0.075		
New initial	0.200		0.200		0.600
Change	-x		-x		+x
New equilibrium	$0.200 - x$		$0.200 - x$		$0.600 + x$ (0.637)*

\*Experimentally determined value.

**Figure 17.8** The effect of added  $\text{Cl}_2$  on the  $\text{PCl}_3\text{-Cl}_2\text{-PCl}_5$  system. The original equilibrium concentrations are shown at left (gray region). When  $\text{Cl}_2$  (yellow curve) is added, its concentration increases instantly (vertical part of yellow curve) and then falls gradually as it reacts with  $\text{PCl}_3$  to form more  $\text{PCl}_5$ . Soon, equilibrium is re-established at new concentrations (blue region) but with the same  $K$ .

Now we add enough  $\text{Cl}_2$  to increase its concentration by  $0.075\text{ M}$  to a new  $[\text{Cl}_2]_{\text{init}}$  of  $0.200\text{ M}$ ; the system is no longer at equilibrium since  $Q_c < K_c$ :

$$Q_c = \frac{[\text{PCl}_5]}{[\text{PCl}_3][\text{Cl}_2]} = \frac{0.600}{(0.200)(0.200)} = 15.0 < K_c$$

The reaction proceeds, and the system comes to a new equilibrium position. From Le Châtelier's principle, we predict that adding more reactant will shift the equilibrium position to the right. Experimental measurement shows that the new  $[\text{PCl}_5]_{\text{eq}}$  is  $0.637\text{ M}$ .

Table 17.3 shows a reaction table for the entire process: the original equilibrium position, the disturbance, the (new) initial concentrations, the direction of  $x$  (the change needed to reattain equilibrium), and the new equilibrium position. Figure 17.8 depicts the process.

Let's determine the new equilibrium concentrations. From Table 17.3,

$$[\text{PCl}_5] = 0.600\text{ M} + x = 0.637\text{ M} \quad \text{so} \quad x = 0.037\text{ M}$$

Thus,  $[\text{PCl}_3] = [\text{Cl}_2] = 0.200\text{ M} - x = 0.200\text{ M} - 0.037\text{ M} = 0.163\text{ M}$

Therefore, at equilibrium,

$$K_{c(\text{original})} = \frac{0.600}{(0.200)(0.125)} = 24.0$$

$$K_{c(\text{new})} = \frac{0.637}{(0.163)(0.163)} = 24.0$$

There are several key points to notice about the new equilibrium concentrations:

- As we predicted,  $[\text{PCl}_5]$  ( $0.637\text{ M}$ ) is higher than the original concentration ( $0.600\text{ M}$ ).
- $[\text{Cl}_2]$  ( $0.163\text{ M}$ ) is higher than the *original* equilibrium concentration ( $0.125\text{ M}$ ), but lower than the new initial concentration ( $0.200\text{ M}$ ); thus, the disturbance is *reduced but not eliminated*.
- $[\text{PCl}_3]$  ( $0.163\text{ M}$ ), the other reactant, is lower than the original equilibrium concentration ( $0.200\text{ M}$ ) because some reacted with the added  $\text{Cl}_2$ .
- Most importantly, although the position of equilibrium shifted to the right, *at a given temperature,  $K_c$  does not change with a change in concentration*.

## SAMPLE PROBLEM 17.11

## Predicting the Effect of a Change in Concentration on the Equilibrium Position

**Problem** To improve air quality and obtain a useful product, chemists often remove sulfur from coal and natural gas by treating the contaminant hydrogen sulfide with  $\text{O}_2$ :

What happens to

- (a)  $[\text{H}_2\text{O}]$  if  $\text{O}_2$  is added?      (b)  $[\text{H}_2\text{S}]$  if  $\text{O}_2$  is added?  
 (c)  $[\text{O}_2]$  if  $\text{H}_2\text{S}$  is removed?      (d)  $[\text{H}_2\text{S}]$  if sulfur is added?

**Plan** We write the reaction quotient to see how  $Q_c$  is affected by each disturbance, relative to  $K_c$ . In each case, the effect tells us the direction in which the reaction proceeds for the system to reattain equilibrium and how each concentration changes.

**Solution** Writing the reaction quotient (solid sulfur is not included):  $Q_c = \frac{[\text{H}_2\text{O}]^2}{[\text{H}_2\text{S}]^2[\text{O}_2]}$

- (a) When  $\text{O}_2$  is added, the denominator of  $Q_c$  increases, so  $Q_c < K_c$ . The reaction proceeds to the right until  $Q_c = K_c$  again, so  $[\text{H}_2\text{O}]$  increases.
- (b) As in part (a), when  $\text{O}_2$  is added,  $Q_c < K_c$ . Some  $\text{H}_2\text{S}$  reacts with the added  $\text{O}_2$  as the reaction proceeds to the right, so  $[\text{H}_2\text{S}]$  decreases.
- (c) When  $\text{H}_2\text{S}$  is removed, the denominator of  $Q_c$  decreases, so  $Q_c > K_c$ . As the reaction proceeds to the left to re-form  $\text{H}_2\text{S}$ , more  $\text{O}_2$  forms as well, so  $[\text{O}_2]$  increases.
- (d) The *concentration* of solid S does not change, so it does not appear in the reaction quotient. As long as some S is present, adding more S has no effect, so  $[\text{H}_2\text{S}]$  is unchanged (but see Comment 2 below).

**Check** Apply Le Châtelier's principle to see that the reaction proceeds in the direction that lowers the increased concentration or raises the decreased concentration.

**Comment 1.** As you know, sulfur exists most commonly as  $\text{S}_8$ . How would this change in formula affect the answers? The balanced equation and  $Q_c$  would be

The value of  $K_c$  is different for this equation, but the changes described in the problem have the same effects. Thus, shifts in equilibrium position predicted by Le Châtelier's principle are not affected by a change in the balancing coefficients.

2. In part (d), you saw that adding a solid has no effect on the concentrations of other components: because *the concentration of the solid cannot change*, it does not appear in  $Q$ . But *the amount of solid can change*. Adding  $\text{H}_2\text{S}$  shifts the reaction to the right, so more S forms.

### FOLLOW-UP PROBLEMS

**17.11A** In a study of glass etching, a chemist examines the reaction between sand ( $\text{SiO}_2$ ) and hydrogen fluoride at  $150^\circ\text{C}$ :

Predict the effect on  $[\text{SiF}_4]$  when

- (a)  $\text{H}_2\text{O}(g)$  is removed.                      (b) some liquid water is added.  
 (c) HF is removed.                              (d) some sand is removed.

**17.11B** Water gas, a fuel mixture of carbon monoxide and hydrogen, is produced by passing steam over hot carbon:

For each of the following changes, what happens to  $[\text{CO}]$ ?

- (a) Carbon is added.                              (b)  $\text{H}_2\text{O}(g)$  is removed.  
 (c)  $\text{H}_2(g)$  is removed.                              (d)  $\text{H}_2\text{O}(g)$  is added.

**SOME SIMILAR PROBLEMS** 17.64 and 17.65

## The Effect of a Change in Pressure (Volume)

Changes in pressure can have a large effect on equilibrium systems containing gaseous components. (A change in pressure has a negligible effect on liquids and solids because they are nearly incompressible.) Pressure changes can occur in three ways:

- *Changing the concentration of a gaseous component.* We just considered the effect of changing the concentration of a component, and that reasoning applies here.
- *Adding an inert gas (one that does not take part in the reaction).* As long as the volume of the system is constant, adding an inert gas has no effect on the equilibrium position because *all concentrations, and thus partial pressures, remain the same*. Moreover, the inert gas does not appear in  $Q$ , so it cannot have an effect.
- *Changing the volume of the reaction vessel.* This change can cause a large shift in equilibrium position, but only for reactions in which the number of moles of gas,  $n_{\text{gas}}$ , changes.

Let's consider the two possible situations for the third way: changing the volume of the reaction vessel.

1. *Reactions in which  $n_{\text{gas}}$  changes.* Suppose the  $\text{PCl}_3\text{-Cl}_2\text{-PCl}_5$  system is in a piston-cylinder assembly. We press down on the piston to halve the volume, so the gas pressure doubles (recall that pressure and volume are inversely proportional—Boyle's law). To reduce this disturbance, the system responds by *reducing the number of gas molecules* in order to reduce the pressure. And the only way to do that is through a net reaction toward the side with *fewer moles of gas*, in this case, toward product:

Recall that  $Q_c = \frac{[\text{PCl}_5]}{[\text{PCl}_3][\text{Cl}_2]}$  for this reaction. When the volume is halved, the concentrations double, but the denominator of  $Q_c$  is the product of two concentrations, so it quadruples while the numerator only doubles. Thus,  $Q_c$  becomes less than  $K_c$ . As a result, the system forms more  $\text{PCl}_5$  and a new equilibrium position is reached.

Thus, for a system that consists of gases at equilibrium, in which the amount (mol) of gas,  $n_{\text{gas}}$ , changes during the reaction (Figure 17.9):

- If the volume becomes smaller (pressure is higher), the reaction shifts so that the total number of gas molecules decreases.
- If the volume becomes larger (pressure is lower), the reaction shifts so that the total number of gas molecules increases.

2. *Reactions in which  $n_{\text{gas}}$  does **not** change.* For the formation of hydrogen iodide from its elements, we have the same amount (mol) of gas on both sides:

Therefore,  $Q_c$  has the same number of terms in the numerator and denominator:

$$Q_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{[\text{HI}][\text{HI}]}{[\text{H}_2][\text{I}_2]}$$

Because a change in volume has the same effect on the numerator and denominator, *there is **no** effect on the equilibrium position.*

In terms of the equilibrium constant, *a change in volume is, in effect, a change in concentration:* a decrease in volume raises the concentration, and vice versa. Therefore, like other changes in concentration, *a change in pressure due to a change in volume does **not** alter  $K_c$ .*

### Student Hot Spot

Student data indicate that you may struggle with using Le Chatelier's Principle to predict a change in equilibrium. Access the Smartbook to view additional Learning Resources on this topic.

**Figure 17.9** The effect of a change in pressure (volume) on a system at equilibrium.

### SAMPLE PROBLEM 17.12

### Predicting the Effect of a Change in Volume (Pressure) on the Equilibrium Position

**Problem** How would you change the volume for each of the following reactions to *increase* the yield of the product(s)?

- (a)  $\text{CaCO}_3(\text{s}) \rightleftharpoons \text{CaO}(\text{s}) + \text{CO}_2(\text{g})$       (b)  $\text{S}(\text{s}) + 3\text{F}_2(\text{g}) \rightleftharpoons \text{SF}_6(\text{g})$   
 (c)  $\text{Cl}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2\text{ICl}(\text{g})$

**Plan** Whenever gases are present, a change in volume causes a change in concentration. For reactions in which the number of moles of gas changes, if the volume decreases (pressure increases), the equilibrium position shifts to lower the pressure by reducing the number of moles of gas. A volume increase (pressure decrease) has the opposite effect.

**Solution** (a) The only gas is the product  $\text{CO}_2$ . To make the system produce more molecules of gas, that is, more  $\text{CO}_2$ , we increase the volume (decrease the pressure).

(b) With 3 mol of gas on the left and only 1 mol on the right, we decrease the volume (increase the pressure) to form fewer molecules of gas and, thus, more  $\text{SF}_6$ .

(c) The number of moles of gas is the same on both sides of the equation, so a change in volume (pressure) will have no effect on the yield of  $\text{ICl}$ .

**Check** Let's predict the relative values of  $Q_c$  and  $K_c$ .

(a)  $Q_c = [\text{CO}_2]$ , so increasing the volume will make  $Q_c < K_c$ , and the system will yield more  $\text{CO}_2$ .

(b)  $Q_c = [\text{SF}_6]/[\text{F}_2]^3$ . Lowering the volume increases  $[\text{F}_2]$  and  $[\text{SF}_6]$  proportionately, but  $Q_c$  decreases because of the exponent 3 in the denominator. To make  $Q_c = K_c$  again,  $[\text{SF}_6]$  must increase.

(c)  $Q_c = [\text{ICl}]^2/[\text{Cl}_2][\text{I}_2]$ . A change in volume (pressure) affects the numerator (2 mol) and denominator (2 mol) equally, so it will have no effect.

### FOLLOW-UP PROBLEMS

**17.12A** Would you increase or decrease the pressure (via a volume change) of each of the following reaction mixtures to *decrease* the yield of product(s)?

**17.12B** Predict the effect of an increase in container volume (decrease in  $P$ ) on the yield of products in each of the following:

**SOME SIMILAR PROBLEMS** 17.66–17.71

## The Effect of a Change in Temperature

Of the three types of disturbances that may occur—a change in concentration, pressure, or temperature—*only temperature changes alter the value of  $K$* . To see why, let's focus on the sign of  $\Delta H_{\text{rxn}}^\circ$ :

The forward reaction is exothermic (releases heat;  $\Delta H_{\text{rxn}}^\circ < 0$ ), so the reverse reaction is endothermic (absorbs heat;  $\Delta H_{\text{rxn}}^\circ > 0$ ):

If we consider *heat as a component of the equilibrium system*, a rise in temperature occurs when heat is “added” to the system and a drop in temperature occurs when heat is “removed” from the system. As with a change in any other component, the system shifts to reduce the effect of the change. Therefore, *a temperature increase (adding heat) favors the endothermic (heat-absorbing) direction, and a temperature decrease (removing heat) favors the exothermic (heat-releasing) direction.*

If we start with the system at equilibrium,  $Q_c$  equals  $K_c$ . Increase the temperature, and the system absorbs the added heat by decomposing some  $\text{PCl}_5$  to  $\text{PCl}_3$  and  $\text{Cl}_2$ . The denominator of  $Q_c$  becomes larger and the numerator smaller, so the system reaches a new equilibrium position at a smaller ratio of concentration terms, that is, a lower  $K_c$ . Similarly, if the temperature drops, the system releases more heat by forming more  $\text{PCl}_5$  from some  $\text{PCl}_3$  and  $\text{Cl}_2$ . The numerator of  $Q_c$  becomes larger, the denominator smaller, and the new equilibrium position has a higher  $K_c$ . Thus,

- A temperature rise will increase  $K_c$  for a system with a positive  $\Delta H_{\text{rxn}}^\circ$ .
- A temperature rise will decrease  $K_c$  for a system with a negative  $\Delta H_{\text{rxn}}^\circ$ .

Let's review these ideas with a sample problem.

**SAMPLE PROBLEM 17.13**
**Predicting the Effect of a Change in Temperature on the Equilibrium Position**

**Problem** How does an *increase* in temperature affect the equilibrium concentration of the underlined substance and  $K$  for each of the following reactions?

**Plan** We write each equation to show heat as a reactant or product. The temperature increases when we add heat, so the system shifts to absorb the heat; that is, the endothermic reaction occurs. Thus,  $K$  will increase if the forward reaction is endothermic and decrease if it is exothermic.

**Solution** (a)  $\text{CaO}(s) + \text{H}_2\text{O}(l) \rightleftharpoons \text{Ca(OH)}_2(aq) + \text{heat}$

Adding heat shifts the system to the left:  $[\text{Ca(OH)}_2]$  and  $K$  will decrease.

Adding heat shifts the system to the right:  $[\text{CO}_2]$  and  $K$  will increase.

Adding heat shifts the system to the right:  $[\text{SO}_2]$  will decrease and  $K$  will increase.

**Check** Check your answers by reasoning through a *decrease* in temperature: heat is removed and the exothermic direction is favored. All the answers should be opposite.

**Comment** Note that, as part (a) shows, these ideas hold for solutions as well.

**FOLLOW-UP PROBLEMS**

**17.13A** How does a *decrease* in  $T$  affect the partial pressure of the underlined substance and the value of  $K$  for each of the following reactions?

**17.13B** Should  $T$  be increased or decreased to yield more product(s) in each of the following reactions? What effect does the change in  $T$  have on the value of  $K$  for each reaction?

**SOME SIMILAR PROBLEMS** 17.72 and 17.73

**The van't Hoff Equation: The Effect of  $T$  on  $K$**  The *van't Hoff equation* shows quantitatively how the equilibrium constant is affected by changes in temperature:

$$\ln \frac{K_2}{K_1} = -\frac{\Delta H_{\text{rxn}}^\circ}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right) \quad (17.10)$$

where  $K_1$  is the equilibrium constant at  $T_1$ ,  $K_2$  is the equilibrium constant at  $T_2$ , and  $R$  is the universal gas constant (8.314 J/mol·K). If we know  $\Delta H_{\text{rxn}}^\circ$  and  $K$  at one temperature, the van't Hoff equation allows us to find  $K$  at any other temperature (or to find  $\Delta H_{\text{rxn}}^\circ$ , given the two  $K$ 's at two  $T$ 's).

Equation 17.10 confirms the qualitative prediction from Le Châtelier's principle: for a temperature rise, we have

$$T_2 > T_1 \quad \text{and} \quad 1/T_2 < 1/T_1$$

$$\text{so} \quad 1/T_2 - 1/T_1 < 0$$

Therefore,

- For an endothermic reaction ( $\Delta H_{\text{rxn}}^\circ > 0$ ), the  $-(\Delta H_{\text{rxn}}^\circ/R)$  term in Equation 17.10 is  $< 0$ . With  $1/T_2 - 1/T_1 < 0$ , the right side of the equation is  $> 0$ . Thus,  $\ln(K_2/K_1) > 0$ , so  $K_2 > K_1$ . An increase in temperature results in a shift to the right and an increase in  $K$ .

- For an exothermic reaction ( $\Delta H_{\text{rxn}}^{\circ} < 0$ ), the  $-(\Delta H_{\text{rxn}}^{\circ}/R)$  term in Equation 17.10 is  $> 0$ . With  $1/T_2 - 1/T_1 < 0$ , the right side of the equation is  $< 0$ . Thus,  $\ln(K_2/K_1) < 0$ , so  $K_2 < K_1$ . An increase in temperature results in a shift to the left and a decrease in  $K$ .

Here's a typical problem that requires the van't Hoff equation. Many coal gasification processes begin with the formation of syngas from carbon and steam:

An engineer knows that  $K_p$  is only  $9.36 \times 10^{-17}$  at  $25^{\circ}\text{C}$  and therefore wants to find a temperature that allows a much higher yield. Calculate  $K_p$  at  $700.^{\circ}\text{C}$ .

$$\ln \frac{K_2}{K_1} = -\frac{\Delta H_{\text{rxn}}^{\circ}}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right)$$

The temperatures must be in kelvins, and the units of  $\Delta H^{\circ}$  and  $R$  must be made consistent:

$$\ln \left( \frac{K_{p2}}{9.36 \times 10^{-17}} \right) = -\frac{131 \times 10^3 \text{ J/mol}}{8.314 \text{ J/mol}\cdot\text{K}} \left( \frac{1}{973 \text{ K}} - \frac{1}{298 \text{ K}} \right)$$

$$\frac{K_{p2}}{9.36 \times 10^{-17}} = 8.51 \times 10^{15}$$

$$K_{p2} = 0.797 \quad (\text{a much higher yield})$$

(For further practice with the van't Hoff equation, see Problems 17.74 and 17.75.)

## The Lack of Effect of a Catalyst

Let's briefly consider what effect, if any, adding a catalyst will have on the system. Recall from Chapter 16 that a catalyst speeds up a reaction by lowering the activation energy, thereby increasing the forward *and* reverse rates to the same extent. Thus, *a catalyst shortens the time it takes to reach equilibrium but has no effect on the equilibrium position.* That is, if we add a catalyst to a mixture of  $\text{PCl}_3$  and  $\text{Cl}_2$  at  $523 \text{ K}$ , the system attains the *same* equilibrium concentrations of  $\text{PCl}_3$ ,  $\text{Cl}_2$ , and  $\text{PCl}_5$  *more quickly* than it does without the catalyst. As you'll see in a moment, however, catalysts play key roles in optimizing reaction systems.

Table 17.4 summarizes the effects of changing conditions. Many changes alter the equilibrium *position*, but only temperature changes alter the equilibrium *constant*. Sample Problem 17.14 shows how to visualize equilibrium at the molecular level.

Table 17.4

Effects of Various Disturbances on a System at Equilibrium

Disturbance	Effect on Equilibrium Position	Effect on Value of $K$
<b>Concentration</b>		
Increase [reactant]	Toward formation of product	None
Decrease [reactant]	Toward formation of reactant	None
Increase [product]	Toward formation of reactant	None
Decrease [product]	Toward formation of product	None
<b>Pressure</b>		
Increase $P$ (decrease $V$ )	Toward formation of fewer moles of gas	None
Decrease $P$ (increase $V$ )	Toward formation of more moles of gas	None
Increase $P$ (add inert gas, no change in $V$ )	None; concentrations unchanged	None
<b>Temperature</b>		
Increase $T$	Toward absorption of heat	Increases if $\Delta H_{\text{rxn}}^{\circ} > 0$ Decreases if $\Delta H_{\text{rxn}}^{\circ} < 0$
Decrease $T$	Toward release of heat	Increases if $\Delta H_{\text{rxn}}^{\circ} < 0$ Decreases if $\Delta H_{\text{rxn}}^{\circ} > 0$
<b>Catalyst added</b>	None; forward and reverse rates increase equally, and equilibrium is reached sooner	None

## SAMPLE PROBLEM 17.14

## Determining Equilibrium Parameters from Molecular Scenes

**Problem** For the reaction,

the following molecular scenes depict different reaction mixtures (X is green, Y is purple):

(a) If  $K = 2$  at the temperature of the reaction, which scene represents the mixture at equilibrium? (b) Will the reaction mixtures in the other two scenes proceed toward reactants or toward products to reach equilibrium? (c) For the mixture at equilibrium, how will a rise in temperature affect  $[\text{Y}_2]$ ?

**Plan** (a) We are given the balanced equation and  $K$  and must choose the scene that represents the mixture at equilibrium. We write  $Q$ , and for each scene, count particles and find the value of  $Q$ . Whichever scene gives a  $Q$  equal to  $K$  (that is, equal to 2) represents the mixture at equilibrium. (b) For each of the other two reaction mixtures, we compare the value of  $Q$  with 2. If  $Q > K$ , the numerator (product side) is too high, so the reaction proceeds toward reactants; if  $Q < K$ , the reaction proceeds toward products. (c) We are given that  $\Delta H > 0$ , so we must see whether a rise in  $T$  increases or decreases  $[\text{Y}_2]$ , one of the reactants.

**Solution** (a) For the reaction, we have  $Q = \frac{[\text{XY}][\text{Y}]}{[\text{X}][\text{Y}_2]}$ . Thus,

$$\text{scene 1: } Q = \frac{5 \times 3}{1 \times 1} = 15 \quad \text{scene 2: } Q = \frac{4 \times 2}{2 \times 2} = 2 \quad \text{scene 3: } Q = \frac{3 \times 1}{3 \times 3} = \frac{1}{3}$$

For scene 2,  $Q = K$ , so scene 2 represents the mixture at equilibrium.

(b) For scene 1,  $Q$  (15)  $>$   $K$  (2), so the reaction proceeds toward reactants.

For scene 3,  $Q$  ( $\frac{1}{3}$ )  $<$   $K$  (2), so the reaction proceeds toward products.

(c) The reaction is endothermic, so heat acts as a reactant:

Therefore, adding heat shifts the reaction to the right, so  $[\text{Y}_2]$  decreases.

**Check** (a) Remember that quantities in the numerator (or denominator) of  $Q$  are multiplied, not added. For example, the denominator for scene 1 is  $1 \times 1 = 1$ , not  $1 + 1 = 2$ .

(c) A good check is to imagine that  $\Delta H < 0$  and see if you get the opposite result:

If  $\Delta H < 0$ , adding heat would shift the reaction to the left and increase  $[\text{Y}_2]$ .

## FOLLOW-UP PROBLEMS

**17.14A** For the reaction  $\text{C}_2(g) + \text{D}_2(g) \rightleftharpoons 2\text{CD}(g)$ , for which  $\Delta H < 0$ , these molecular scenes depict different reaction mixtures (C is red, D is blue):

At equilibrium

(a) Calculate the value of  $K_p$ . (b) In which direction will the reaction proceed for the mixtures *not* at equilibrium? (c) For the mixture at equilibrium, what effect will a rise in  $T$  have on the total amount (mol) of gas (increase, decrease, no effect)? Explain.

**17.14B** For the reaction  $A(g) + B(g) \rightleftharpoons AB(g)$ , these molecular scenes depict reaction mixtures at two different temperatures (A is red, B is green):

(a) Calculate the value of  $K$  at  $T_1$ . (b) If  $T_2 < T_1$ , what is the sign of  $\Delta H$  for the reaction? (c) Calculate  $K$  at  $T_2$ .

**SOME SIMILAR PROBLEMS** 17.60 and 17.81

## Applying Le Châtelier's Principle to the Synthesis of Ammonia

Le Châtelier's principle has countless applications in natural systems and in the chemical industry. As a case study, we'll look at the synthesis of ammonia, which, on a mole basis, is produced industrially in greater amount than any other compound. Then, a Chemical Connections essay applies the principle to cellular metabolism.

Even though four of every five molecules in the atmosphere are  $N_2$ , the supply of *usable* nitrogen is limited because the strong triple bond in  $N_2$  lowers its reactivity. Thus, the N atom is very difficult to “fix,” that is, to combine with other atoms into useful compounds. Natural nitrogen fixation occurs through the fine-tuned activity of enzymes found in bacteria that live on plant roots, or through the brute force of lightning. But, nearly 13% of nitrogen fixation is done industrially via the **Haber process**:

Developed by the German chemist Fritz Haber in 1913 and first used in a plant making 12,000 tons of ammonia a year, the process now yields over 110 million tons a year. Over 80% of this is used as fertilizer, with most of the remainder used to make explosives and nylons and other polymers, and smaller amounts going into production of refrigerants, rubber stabilizers, household cleaners, and pharmaceuticals.

**Optimizing Reaction Conditions: Yield vs. Rate** The Haber process applies equilibrium *and* kinetics principles to achieve a compromise that makes the process economical. From the balanced equation, we see three ways to maximize  $NH_3$  yield:

1. *Decrease  $[NH_3]$ .* Removing  $NH_3$  as it forms will make the system shift toward producing more to reattain equilibrium.
2. *Decrease volume (increase pressure).* Because 4 mol of reactant gases react to form 2 mol of product gas, decreasing the volume will shift the system toward making fewer moles of gas.
3. *Decrease temperature.* Because the formation of  $NH_3$  is exothermic, decreasing the temperature (removing heat) will shift the equilibrium position toward product, thereby increasing  $K_c$  (Table 17.5).

Therefore, the conditions for maximizing the yield of product are continual removal of  $NH_3$ , high pressure, and low temperature. Figure 17.10 on the next page shows the percent yield of  $NH_3$  at various combinations of pressure and temperature. Note the almost complete conversion (98.3%) to product at 1000 atm and 473 K (200.°C).

Although the *yield* is favored at this relatively low temperature, the *rate* of formation is so low that the process is uneconomical. The higher temperatures that would increase reaction rate would also result in a lower yield. In practice, a compromise optimizes yield *and* rate. High pressure and continuous removal are used to increase yield, but the temperature is raised to a moderate level and *a catalyst is used to increase the rate*. Achieving the same rate without a catalyst would require much higher temperatures and, thus, result in a much lower yield.

**Effect of Temperature on  $K_c$  for Ammonia Synthesis**

**Table 17.5**

$T$ (K)	$K_c$
200.	$7.17 \times 10^{15}$
300.	$2.69 \times 10^8$
400.	$3.94 \times 10^4$
500.	$1.72 \times 10^2$
600.	$4.53 \times 10^0$
700.	$2.96 \times 10^{-1}$
800.	$3.96 \times 10^{-2}$

**Figure 17.10** Percent yield of ammonia vs. temperature at five different pressures. At very high  $P$  and low  $T$  (top left), the yield is high, but the rate is low. Industrial conditions (circle) are between 200 and 300 atm at about 400°C.

**The Industrial Process** Stages in the industrial production of  $\text{NH}_3$  are shown in Figure 17.11. To extend equipment life and minimize cost, modern plants operate at about 200 to 300 atm and around 673 K (400°C). The stoichiometric ratio of reactant gases ( $\text{N}_2/\text{H}_2 = 1/3$  by volume) is injected into the heated, pressurized reaction chamber. Some of the needed heat is supplied by  $\Delta H_{\text{rxn}}^\circ$ . The gases flow over catalyst beds that consist of 5-mm to 10-mm chunks of iron crystals embedded in a fused mixture of  $\text{MgO}$ ,  $\text{Al}_2\text{O}_3$ , and  $\text{SiO}_2$ . The emerging equilibrium mixture contains about 35%  $\text{NH}_3$  and is cooled by refrigeration until the  $\text{NH}_3$  (bp  $-33.4^\circ\text{C}$ ) condenses; it is then removed and stored. Because  $\text{N}_2$  and  $\text{H}_2$  have much lower boiling points, they are recycled as gases by pumping them back into the reaction chamber.

**Figure 17.11** Key stages in the Haber process for synthesizing ammonia.

### › Summary of Section 17.6

- › If a system at equilibrium is disturbed, it undergoes a net reaction that reduces the disturbance and returns the system to equilibrium.
- › Changes in concentration cause a net reaction to consume the added component or to produce the removed component.
- › For a reaction that involves a change in amount (mol) of gas, an increase in pressure (decrease in volume) causes a net reaction toward fewer moles of gas, and a decrease in pressure causes the opposite change.
- › Although the equilibrium position changes as a result of a concentration or volume change,  $K$  does not.
- › A temperature change affects  $K$ : higher  $T$  increases  $K$  for an endothermic reaction (positive  $\Delta H_{\text{rxn}}^\circ$ ) and decreases  $K$  for an exothermic reaction (negative  $\Delta H_{\text{rxn}}^\circ$ ).
- › A catalyst causes the system to reach equilibrium more quickly by speeding forward and reverse reactions equally, but it does not affect the equilibrium position.
- › Ammonia is produced in a process favored by high pressure, low temperature, and continual removal of product. To make the process economical, intermediate temperature and pressure and a catalyst are used.
- › A metabolic pathway is a cellular reaction sequence with each step shifted completely toward product. Its overall yield is controlled by a feedback system that inhibits the activity of certain key enzymes.

From the simplest bacterium to the most specialized neuron, every cell performs thousands of reactions that allow it to grow and reproduce, feed and excrete, move and communicate. Taken together, these myriad feats of breakdown, synthesis, and energy flow constitute the cell's *metabolism* and are organized into reaction sequences called **metabolic pathways**.

### Continual Shift Toward Product

In principle, each step in a metabolic pathway is a reversible reaction catalyzed by a specific enzyme (Section 16.7). However, equilibrium is never reached in a pathway, because the product of each reaction becomes the reactant of the next. Consider the five-step pathway by which the amino acid threonine is converted into the amino acid isoleucine (Figure B17.1). Threonine, supplied from a different region of the cell, forms ketobutyrate through the catalytic action of enzyme 1. The equilibrium position of reaction 1 shifts to the right because the product, ketobutyrate, is the reactant in reaction 2. Similarly, reaction 2 shifts to the right as its product, aceto-hydroxybutyrate, is used up in reaction 3. In this way, each subsequent reaction shifts the previous reaction to the right. The final product, isoleucine, is removed to make proteins elsewhere in the cell. Thus, the entire pathway operates in one direction.

### Creation of a Steady State

This continuous shift in equilibrium position has two consequences for metabolic pathways:

1. *Each step proceeds with nearly 100% yield:* Virtually every molecule of threonine that enters this region of the cell eventually changes to ketobutyrate, every molecule of ketobutyrate to the next product, and so on.
2. *Reactant and product concentrations remain nearly constant,* because they reach a *steady state*.
  - In an equilibrium system, equal rates in *opposing* directions create constant concentrations of reactants and products.
  - In a steady-state system, the rates of reactions in *one* direction—into, through, and out of the system—create constant concentrations of intermediates.

Ketobutyrate, for example, is formed in reaction 1 as fast as it is consumed in reaction 2, so its concentration is constant. (A steady-state amount of water results if you fill a sink and then adjust the flow of faucet and drain so that water enters as fast as it leaves.)

### Regulation by Feedback Inhibition

Recall from Chapter 16 that substrate concentrations are *much* higher than enzyme concentrations. If the active sites on all the

**Figure B17.1** The biosynthesis of isoleucine from threonine. Isoleucine is synthesized from threonine in a sequence of five enzyme-catalyzed reactions. Once enough isoleucine is present, its concentration builds up and inhibits threonine dehydratase, the first enzyme in the pathway.

Substrate can bind to active site when inhibitor is absent, so catalysis occurs.

Active site is deformed when inhibitor is present, so substrate cannot bind and no catalysis occurs.

**Figure B17.2** Effect of inhibitor binding on shape of active site.

enzyme molecules were always occupied, all cellular reactions would occur at their maximum rates. This might be ideal for an industrial process, but an organism needs to control amounts carefully. To regulate product formation, certain key steps are catalyzed by *regulatory enzymes*, which contain an *inhibitor site* (Figure B17.2A) in addition to an active site: when the inhibitor site is occupied, the shape of the active site is deformed and the reaction is not catalyzed (Figure B17.2B).

In the simplest case of metabolic regulation (Figure B17.1), *the final product of a pathway is the inhibitor, and the regulatory enzyme catalyzes the first step*. Suppose, for instance, that a cell is temporarily making less protein, so isoleucine is not being removed as quickly. As its concentration rises, isoleucine lands more often on the inhibitor site of threonine dehydratase, the first enzyme in the pathway, thereby inhibiting its own production. This process is called *end-product feedback inhibition*. More complex pathways have more elaborate regulatory schemes.

### Problem

**B17.1** Many metabolites are products in branched pathways. In the one below, letters are compounds, and numbers are enzymes:

One method of control of these pathways occurs through inhibition of the first enzyme specific for a branch. (a) Which enzyme is inhibited by F? (b) Which enzyme is inhibited by I? (c) What is the disadvantage if F inhibited enzyme 1? (d) What would be the disadvantage if F inhibited enzyme 6?

## CHAPTER REVIEW GUIDE

## Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. The distinction between the speed (rate) and the extent of a reaction (Introduction)
2. Why a system attains dynamic equilibrium when forward and reverse reaction rates are equal (§17.1)
3. The equilibrium constant as a number that is equal to a particular ratio of rate constants and of concentration terms (§17.1)
4. How the magnitude of  $K$  is related to the extent of the reaction (§17.1)
5. Why the same equilibrium state is reached no matter what the starting concentrations of the reacting system (§17.2)
6. How the reaction quotient ( $Q$ ) changes continuously until the system reaches equilibrium, at which point  $Q = K$  (§17.2)
7. Why the form of  $Q$  is based exactly on the balanced equation as written (§17.2)
8. Why terms for pure solids and liquids do not appear in  $Q$  (§17.2)
9. How the *sum* of reaction steps gives the overall reaction, and the *product* of  $Q$ 's (or  $K$ 's) gives the overall  $Q$  (or  $K$ ) (§17.2)
10. How the interconversion of  $K_c$  and  $K_p$  is based on the ideal gas law and  $\Delta n_{\text{gas}}$  (§17.3)
11. How the reaction direction depends on the relative values of  $Q$  and  $K$  (§17.4)
12. How a reaction table is used to find an unknown quantity (concentration or pressure) (§17.5)
13. How assuming that the change in [reactant] is relatively small simplifies finding equilibrium quantities (§17.5)
14. How Le Châtelier's principle explains the effects of a change in concentration, pressure (volume), or temperature on a system at equilibrium and on  $K$  (§17.6)
15. Why a change in temperature *does* affect  $K$  (§17.6)
16. Why the addition of a catalyst *does not* affect  $K$  (§17.6)
17. How adjusting reaction conditions and using a catalyst optimizes the synthesis of ammonia (§17.6)

## Master These Skills

1. Writing a reaction quotient ( $Q$ ) from a balanced equation (SP 17.1)
2. Writing  $Q$  and finding  $K$  for a reaction multiplied by a common factor or reversed and for an overall reaction (SP 17.2)
3. Writing  $Q$  for heterogeneous equilibria (§17.2)
4. Converting between  $K_c$  and  $K_p$  (SP 17.3)
5. Comparing  $Q$  and  $K$  to determine reaction direction (SPs 17.4, 17.5)
6. Substituting quantities (concentrations or pressures) into  $Q$  to find  $K$  (§17.5)
7. Using a reaction table to determine quantities and find  $K$  (SP 17.6)
8. Finding one equilibrium quantity from other equilibrium quantities and  $K$  (SP 17.7)
9. Finding an equilibrium quantity from initial quantities and  $K$  (SP 17.8)
10. Solving a quadratic equation for an unknown equilibrium quantity (§17.5)
11. Assuming that the change in [reactant] is relatively small to find equilibrium quantities and checking the assumption (SP 17.9)
12. Comparing the values of  $Q$  and  $K$  to find reaction direction and  $x$ , the unknown change in a quantity (SP 17.10)
13. Using the relative values of  $Q$  and  $K$  to predict the effect of a change in concentration on the equilibrium position and on  $K$  (SP 17.11)
14. Using Le Châtelier's principle and  $\Delta n_{\text{gas}}$  to predict the effect of a change in pressure (volume) on the equilibrium position (SP 17.12)
15. Using Le Châtelier's principle and  $\Delta H^\circ$  to predict the effect of a change in temperature on the equilibrium position and on  $K$  (SP 17.13)
16. Using the van't Hoff equation to calculate  $K$  at one temperature given  $K$  at another temperature (§17.6)
17. Using molecular scenes to find equilibrium parameters (SP 17.14)

## Key Terms

Page numbers appear in parentheses.

equilibrium constant ( $K$ ) (749)  
Haber process (779)

law of chemical equilibrium  
(law of mass action) (750)

Le Châtelier's principle (770)  
metabolic pathway (781)

reaction quotient ( $Q$ ) (750)

## Key Equations and Relationships

Page numbers appear in parentheses.

**17.1** Defining equilibrium in terms of reaction rates (748):

$$\text{At equilibrium: rate}_{\text{fwd}} = \text{rate}_{\text{rev}}$$

**17.2** Defining the equilibrium constant for the reaction

$A \rightleftharpoons 2B$  (749):

$$K = \frac{k_{\text{fwd}}}{k_{\text{rev}}} = \frac{[\text{B}]_{\text{eq}}^2}{[\text{A}]_{\text{eq}}}$$

**17.3** Defining the equilibrium constant in terms of the reaction quotient (750):

$$\text{At equilibrium: } Q = K$$

**17.4** Expressing  $Q_c$  for the reaction  $aA + bB \rightleftharpoons cC + dD$  (751):

$$Q_c = \frac{[\text{C}]^c [\text{D}]^d}{[\text{A}]^a [\text{B}]^b}$$

**17.5** Finding  $K$  of a reaction from  $K$  of the reverse reaction (753):

$$K_{\text{fwd}} = \frac{1}{K_{\text{rev}}}$$

**17.6** Finding  $Q$  and  $K$  of a reaction multiplied by a factor  $n$  (754):

$$Q' = Q^n = \left( \frac{[\text{C}]^c [\text{D}]^d}{[\text{A}]^a [\text{B}]^b} \right)^n \quad \text{and} \quad K' = K^n$$

**17.7** Finding the overall  $K$  for a reaction sequence (754):

$$K_{\text{overall}} = K_1 \times K_2 \times K_3 \times \dots$$

**17.8** Relating  $K$  based on pressures to  $K$  based on concentrations (757):

$$K_p = K_c (RT)^{\Delta n_{\text{gas}}}$$

**17.9** Assuming that ignoring the concentration that reacts introduces no significant error (766):

$$[\text{A}]_{\text{init}} - [\text{A}]_{\text{reacting}} = [\text{A}]_{\text{eq}} \approx [\text{A}]_{\text{init}}$$

**17.10** Finding  $K$  at one temperature given  $K$  at another (van't Hoff equation) (776):

$$\ln \frac{K_2}{K_1} = - \frac{\Delta H_{\text{rxn}}^\circ}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right)$$

### BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

**17.1A** (a)  $Q_c = \frac{[\text{NO}]^4 [\text{H}_2\text{O}]^6}{[\text{NH}_3]^4 [\text{O}_2]^5}$

(b)  $Q_c = \frac{[\text{NH}_3]^2}{[\text{NO}_2]^2 [\text{H}_2]^7}$  (Liquid  $\text{H}_2\text{O}$  is not included.)

(c)  $Q_c = [\text{O}_2]^3$  (Solid  $\text{KClO}_3$  and  $\text{KCl}$  are not included.)

**17.1B** (a)  $Q_c = \frac{[\text{CO}]^2 [\text{H}_2]^2}{[\text{CH}_4] [\text{CO}_2]}$

(b)  $Q_c = \frac{[\text{H}_2\text{O}]^2}{[\text{H}_2\text{S}]^2 [\text{SO}_2]}$  (Solid  $\text{S}$  is not included.)

(c)  $Q_c = \frac{[\text{NaCN}]}{[\text{HCN}] [\text{NaOH}]}$  (Liquid  $\text{H}_2\text{O}$  is not included.)

**17.2A**

Multiply by 2

$$K_{c(\text{overall})} = K_{c1} \times K_{c2} = (1.4 \times 10^{12})(0.30) = 4.2 \times 10^{11}$$

**17.2B** (a)  $K_c = \left( \frac{1}{K_{c(\text{ref})}} \right)^2 = \left( \frac{1}{1.3 \times 10^{-2}} \right)^2 = 5.9 \times 10^3$

(b)  $K_c = K_{c(\text{ref})}^{1/4} = (1.3 \times 10^{-2})^{1/4} = 0.34$

**17.3A**  $\Delta n_{\text{gas}} = 1 - 2 = -1$

$$K_p = K_c (RT)^{-1} = 1.67 \left( 0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 500. \text{K} \right)^{-1} = 4.07 \times 10^{-2}$$

**17.3B**  $\Delta n_{\text{gas}} = 3 - 5 = -2$  and  $K_p = K_c (RT)^{-2}$

$$K_c = \frac{K_p}{(RT)^{-2}} = K_p (RT)^2 = 3.0 \times 10^{-5} \left( 0.0821 \frac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 1173 \text{K} \right)^2 = 0.28$$

**17.4A**  $K_c = \frac{[\text{Y}]}{[\text{X}]} = 1.4$

Scene 1:  $Q_c = \frac{3}{9} = 0.33$ ;  $Q_c < K_c$ , right

Scene 2:  $Q_c = \frac{7}{5} = 1.4$ ;  $Q_c = K_c$ , no net change

Scene 3:  $Q_c = \frac{8}{4} = 2.0$ ;  $Q_c > K_c$ , left

**17.4B**  $K_c = \frac{[\text{D}]}{[\text{C}]^2} = \frac{5}{3^2} = 0.56$

Scene 2:  $Q_c = \frac{6}{3^2} = 0.67$ ;  $Q_c > K_c$ , left

Scene 3:  $Q_c = \frac{7}{4^2} = 0.44$ ;  $Q_c < K_c$ , right

**17.5A**  $Q_p = \frac{(P_{\text{CH}_3\text{Cl}})(P_{\text{HCl}})}{(P_{\text{CH}_4})(P_{\text{Cl}_2})} = \frac{(0.24)(0.47)}{(0.13)(0.035)} = 25$

$Q_p < K_p$ , so the reaction progresses to the right and  $\text{CH}_3\text{Cl}$  is forming.

**17.5B**  $M_{\text{SO}_2} = \frac{3.4 \text{ mol}}{2.0 \text{ L}} = 1.7 \text{ M}$ ;  $M_{\text{O}_2} = \frac{1.5 \text{ mol}}{2.0 \text{ L}} = 0.75 \text{ M}$

$$M_{\text{SO}_2} = \frac{1.2 \text{ mol}}{2.0 \text{ L}} = 0.60 \text{ M}$$

$$Q_c = \frac{[\text{SO}_3]^2}{[\text{SO}_2]^2 [\text{O}_2]} = \frac{[0.60]^2}{[1.7]^2 [0.75]} = 0.17$$

$Q_c > K_c$ , so the system is not at equilibrium, and the reaction will proceed toward the left.

**17.6A**

Initial	1.000	1.000	0
Change	-2x	-x	+2x

Equilibrium	1.000 - 2x	1.000 - x	2x
-------------	------------	-----------	----

$$P_{\text{O}_2} = 1.000 \text{ atm} - x = 0.506 \text{ atm}, \quad \text{so} \quad x = 0.494 \text{ atm}$$

$$P_{\text{NO}_2} = 2x = 2(0.494 \text{ atm}) = 0.988 \text{ atm}$$

$$P_{\text{NO}} = 1.000 \text{ atm} - 2x = 1.000 \text{ atm} - 2(0.494 \text{ atm}) = 0.012 \text{ atm}$$

$$K_p = \frac{P_{\text{NO}_2}^2}{(P_{\text{NO}})^2 (P_{\text{O}_2})} = \frac{0.988^2}{(0.012)^2 (0.506)} = 1.3 \times 10^4$$

**17.6B**

Initial	2.40	2.40	0	0
Change	-4x	-7x	+2x	+6x

Equilibrium	2.40 - 4x	2.40 - 7x	2x	6x
-------------	-----------	-----------	----	----

$$[\text{N}_2\text{O}_4] = 2x = 0.134 \text{ M}, \quad \text{so} \quad x = 0.0670 \text{ M}$$

$$[\text{NH}_3] = 2.40 - 4x = 2.40 - 4(0.0670) = 2.13 \text{ M}$$

$$[\text{O}_2] = 2.40 - 7x = 2.40 - 7(0.0670) = 1.93 \text{ M}$$

$$[\text{H}_2\text{O}] = 6x = 6(0.0670) = 0.402 \text{ M}$$

$$K_c = \frac{[\text{N}_2\text{O}_4]^2 [\text{H}_2\text{O}]^6}{[\text{NH}_3]^4 [\text{O}_2]^7} = \frac{(0.134)^2 (0.402)^6}{(2.13)^4 (1.93)^7} = 3.69 \times 10^{-8}$$

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

(continued)

**17.7A** Since  $\Delta n_{\text{gas}} = 2 - 2 = 0$ ,

$$K_p = K_c = 2.3 \times 10^{30} = \frac{(P_{\text{N}_2})(P_{\text{O}_2})}{P_{\text{NO}}^2}$$

$$P_{\text{NO}} = \sqrt{\frac{(P_{\text{N}_2})(P_{\text{O}_2})}{2.3 \times 10^{30}}} = \sqrt{\frac{(0.781)(0.209)}{2.3 \times 10^{30}}} = 2.7 \times 10^{-16} \text{ atm}$$

**17.7B**  $K_p = 19.6 = \frac{(P_{\text{P}_2})(P_{\text{H}_2}^3)}{P_{\text{PH}_3}^2}$ 

$$P_{\text{H}_2} = \sqrt[3]{\frac{(P_{\text{PH}_3}^2)(K_p)}{(P_{\text{P}_2})}} = \sqrt[3]{\frac{(0.112)^2(19.6)}{0.215}} = 1.05 \text{ atm}$$

**17.8A**  $M_{\text{HI}} = \frac{2.50 \text{ mol}}{10.32 \text{ L}} = 0.242 \text{ M}$ 

Concentration (M)	2HI(g)	⇌	H <sub>2</sub> (g)	+	I <sub>2</sub> (g)
Initial	0.242		0		0
Change	-2x		+x		+x
Equilibrium	0.242 - 2x		x		x

$$K_c = 1.26 \times 10^{-3} = \frac{[\text{H}_2][\text{I}_2]}{[\text{HI}]^2} = \frac{x^2}{(0.242 - 2x)^2}$$

Taking the square root of both sides, ignoring the negative root, and solving gives  $x = [\text{H}_2] = 8.02 \times 10^{-3} \text{ M}$ .**17.8B**  $M_{\text{Cl}_2\text{O}} = M_{\text{H}_2\text{O}} = \frac{6.15 \text{ mol}}{5.00 \text{ L}} = 1.23 \text{ M}$ 

Concentration (M)	Cl <sub>2</sub> O(g)	+	H <sub>2</sub> O(g)	⇌	2HOCl(g)
Initial	1.23		1.23		0
Change	-x		-x		+2x
Equilibrium	1.23 - x		1.23 - x		2x

$$K_c = 0.18 = \frac{[\text{HOCl}]^2}{[\text{Cl}_2\text{O}][\text{H}_2\text{O}]} = \frac{(2x)^2}{(1.23 - x)^2}$$

Taking the square root of both sides, ignoring the negative root, and solving gives  $x = 0.21 \text{ M}$ .

$$[\text{H}_2\text{O}] = [\text{Cl}_2\text{O}] = 1.23 - x = 1.23 - 0.21 = 1.02 \text{ M}$$

$$[\text{HOCl}] = 2x = 2(0.21) = 0.42 \text{ M}$$

**17.9A** (a)  $M_{\text{I}_2} = \frac{0.50 \text{ mol}}{2.5 \text{ L}} = 0.20 \text{ M}$ 

Concentration (M)	I <sub>2</sub> (g)	⇌	2I(g)
Initial	0.20		0
Change	-x		+2x
Equilibrium	0.20 - x		2x

Assuming that  $0.20 \text{ M} - x \approx 0.20 \text{ M}$ :

$$K_c = 2.94 \times 10^{-10} = \frac{[\text{I}]^2}{[\text{I}_2]} = \frac{(2x)^2}{0.20 - x} \approx \frac{4x^2}{0.20} \quad x \approx 3.8 \times 10^{-6} \text{ M}$$

Error =  $(3.8 \times 10^{-6}/0.20) \times 100 = 1.9 \times 10^{-3}\%$ , so assumption is justified; therefore, at equilibrium,  $[\text{I}_2] = 0.20 \text{ M}$  and  $[\text{I}] = 2x = 2(3.8 \times 10^{-6}) = 7.6 \times 10^{-6} \text{ M}$ .(b) Based on the same reaction table and assumption that  $0.20 \text{ M} - x \approx 0.20 \text{ M}$ :

$$K_c = 0.209 = \frac{[\text{I}]^2}{[\text{I}_2]} = \frac{(2x)^2}{0.20 - x} \approx \frac{4x^2}{0.20} \quad x \approx 0.10 \text{ M}$$

Error is  $(0.10/0.20) \times 100 = 50\%$ , so assumption is *not* justified. Solve the quadratic equation:

$$4x^2 + 0.209x - 0.042 = 0, \quad \text{so} \quad x = 0.080 \text{ M}$$

Therefore, at equilibrium,  $[\text{I}_2] = 0.20 - x = 0.20 - 0.080 = 0.12 \text{ M}$ ; and  $[\text{I}] = 2x = 2(0.080) = 0.16 \text{ M}$ .**17.9B**

(a) Pressure (atm)	PCl <sub>5</sub> (g)	⇌	PCl <sub>3</sub> (g)	+	Cl <sub>2</sub> (g)
Initial	0.18		0		0
Change	-x		+x		+x
Equilibrium	0.18 - x		x		x

Assuming that  $0.18 \text{ atm} - x \approx 0.18 \text{ atm}$ :

$$K_p = 3.4 \times 10^{-4} = \frac{[\text{PCl}_3][\text{Cl}_2]}{[\text{PCl}_5]} = \frac{x^2}{0.18 - x} \approx \frac{x^2}{0.18}$$

 $x \approx 7.8 \times 10^{-3} \text{ atm}$ ; error =  $(7.8 \times 10^{-3}/0.18) \times 100 = 4.3\%$ , so assumption is justified; at equilibrium,

$$P_{\text{PCl}_5} = 0.18 - x = 0.18 - (7.8 \times 10^{-3}) = 0.17 \text{ atm}$$

(b) Pressure (atm)	PCl <sub>5</sub> (g)	⇌	PCl <sub>3</sub> (g)	+	Cl <sub>2</sub> (g)
Initial	0.025		0		0
Change	-x		+x		+x
Equilibrium	0.025 - x		x		x

Assuming that  $0.025 \text{ atm} - x \approx 0.025 \text{ atm}$ :

$$K_p = 3.4 \times 10^{-4} = \frac{[\text{PCl}_3][\text{Cl}_2]}{[\text{PCl}_5]} = \frac{x^2}{0.025 - x} \approx \frac{x^2}{0.025}$$

 $x \approx 2.9 \times 10^{-3} \text{ atm}$ ; error =  $(2.9 \times 10^{-3}/0.025) \times 100 = 12\%$ , so assumption is *not* justified. Solving the quadratic equation:

$$x^2 + 3.4 \times 10^{-4}x - 8.5 \times 10^{-6} = 0, \quad \text{so} \quad x = 0.0028$$

Therefore, at equilibrium,  $P_{\text{PCl}_5} = 0.025 - x = 0.025 - 0.0028 = 0.022 \text{ atm}$ **17.10A** (a)  $M_{\text{PCl}_5} = 0.1050 \text{ mol}/0.5000 \text{ L} = 0.2100 \text{ M}$ ; similarly,  $M_{\text{Cl}_2} = M_{\text{PCl}_3} = 0.0900 \text{ M}$ 

$$Q_c = \frac{[\text{PCl}_3][\text{Cl}_2]}{[\text{PCl}_5]} = \frac{[0.0900][0.0900]}{[0.2100]} = 3.86 \times 10^{-2}$$

 $Q_c < K_c$ , so reaction proceeds to the right.

(b) Concentration (M)	PCl <sub>5</sub> (g)	⇌	PCl <sub>3</sub> (g)	+	Cl <sub>2</sub> (g)
Initial	0.2100		0.0900		0.0900
Change	-x		+x		+x
Equilibrium	0.2100 - x		0.0900 + x		0.0900 + x

$$[\text{PCl}_5] = 0.2100 \text{ M} - x = 0.2065 \text{ M}, \quad \text{so} \quad x = 0.0035 \text{ M}$$

$$[\text{Cl}_2] = [\text{PCl}_3] = 0.0900 \text{ M} + x = 0.0900 \text{ M} + 0.0035 \text{ M} = 0.0935 \text{ M}$$

$$\mathbf{17.10B} \quad Q_p = \frac{[\text{NO}]^2}{[\text{N}_2][\text{O}_2]} = \frac{[0.750]^2}{[0.500][0.500]} = 2.25$$

 $Q_p > K_p$ , so reaction proceeds to the left.

Pressure (atm)	N <sub>2</sub> (g)	+	O <sub>2</sub> (g)	⇌	2NO(g)
Initial	0.500		0.500		0.750
Change	+x		+x		-2x
Equilibrium	0.500 + x		0.500 + x		0.750 - 2x

$$K_p = 8.44 \times 10^{-3} = \frac{P_{\text{NO}}^2}{(P_{\text{N}_2})(P_{\text{O}_2})} = \frac{(0.750 - 2x)^2}{(0.500 + x)^2}$$

Taking the square root of both sides and solving gives  $x = 0.337$ , so

$$P_{\text{N}_2} = P_{\text{O}_2} = 0.500 + x = 0.500 + 0.337 = 0.837 \text{ atm}$$

$$P_{\text{NO}} = 0.750 - 2x = 0.750 - 2(0.337) = 0.076 \text{ atm}$$

**17.11A** (a)  $[\text{SiF}_4]$  increases; (b) decreases since adding  $\text{H}_2\text{O}(l)$  above the boiling point of water results in an increase in the concentration of  $\text{H}_2\text{O}(g)$ ; (c) decreases; (d) no effect.

**17.11B** (a)  $[\text{CO}]$  does not change; (b) decreases; (c) increases; (d) increases.

**17.12A** (a) Decrease  $P$ ; (b) increase  $P$ ; (c) increase  $P$ .

**17.12B** (a) More  $\text{CO}$  and  $\text{H}_2$ ; (b) no change; (c) less  $\text{S}$  and  $\text{H}_2\text{O}$ .

**17.13A** (a)  $P_{\text{H}_2}$  will decrease;  $K$  will increase. (b)  $P_{\text{N}_2}$  will increase;  $K$  will decrease. (c)  $P_{\text{PCl}_5}$  will increase;  $K$  will increase.

**17.13B** (a) Increase  $T$ , and  $K$  increases; (b) decrease  $T$ , and  $K$  increases; (c) increase  $T$ , and  $K$  increases.

**17.14A** (a) Since  $P = \frac{n}{V}RT$  and, in this case,  $V$ ,  $R$ , and  $T$  cancel,

$$K_p = \frac{n_{\text{CD}}^2}{n_{\text{C}_2} \times n_{\text{D}_2}} = \frac{4^2}{2 \times 2} = 4$$

(b) Scene 2:  $Q_p = \frac{(6)^2}{(1)(1)} = 36 > K_p(4)$ ; to the left;

Scene 3:  $Q_p = \frac{(2)^2}{(3)(3)} = 0.44 < K_p(4)$ ; to the right.

(c) There are 2 mol of gas on each side of the balanced equation, so increasing  $T$  has no effect on total moles of gas.

**17.14B** (a)  $K = \frac{[\text{AB}]}{[\text{A}][\text{B}]} = \frac{3}{2 \times 2} = 0.75$

(b)  $\Delta H > 0$

(c)  $K = \frac{2}{3 \times 3} = 0.22$

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

### The Equilibrium State and the Equilibrium Constant

#### Concept Review Questions

**17.1** A change in reaction conditions increases the rate of a certain forward reaction more than that of the reverse reaction. What is the effect on the equilibrium constant and on the concentrations of reactants and products at equilibrium?

**17.2** When a chemical company employs a new reaction to manufacture a product, the chemists consider its rate (kinetics) and yield (equilibrium). How do each of these affect the usefulness of a manufacturing process?

**17.3** If there is no change in concentrations, why is the equilibrium state considered dynamic?

**17.4** Is  $K$  very large or very small for a reaction that goes essentially to completion? Explain.

**17.5** White phosphorus,  $\text{P}_4$ , is produced by the reduction of phosphate rock,  $\text{Ca}_3(\text{PO}_4)_2$ . If exposed to oxygen, the waxy, white solid smokes, bursts into flames, and releases a large quantity of heat:

Does this reaction have a large or small equilibrium constant? Explain.

### The Reaction Quotient and the Equilibrium Constant

(Sample Problems 17.1 to 17.2)

#### Concept Review Questions

**17.6** For a given reaction at a given temperature, the value of  $K$  is constant. Is the value of  $Q$  also constant? Explain.

**17.7** In a study of the thermal decomposition of lithium peroxide,

a chemist finds that, as long as some  $\text{Li}_2\text{O}_2$  is present at the end of the experiment, the amount of  $\text{O}_2$  obtained in a given container at a given  $T$  is the same. Explain.

**17.8** In a study of the formation of  $\text{HI}$  from its elements,

equal amounts of  $\text{H}_2$  and  $\text{I}_2$  were placed in a container, which was then sealed and heated.

(a) On one set of axes, sketch concentration vs. time curves for  $\text{H}_2$  and  $\text{HI}$ , and explain how  $Q$  changes as a function of time.

(b) Is the value of  $Q$  different if  $[\text{I}_2]$  is plotted instead of  $[\text{H}_2]$ ?

**17.9** Explain the difference between a heterogeneous and a homogeneous equilibrium. Give an example of each.

**17.10** Does  $Q$  for the formation of 1 mol of  $\text{NO}$  from its elements differ from  $Q$  for the decomposition of 1 mol of  $\text{NO}$  to its elements? Explain and give the relationship between the two  $Q$ 's.

**17.11** Does  $Q$  for the formation of 1 mol of  $\text{NH}_3$  from  $\text{H}_2$  and  $\text{N}_2$  differ from  $Q$  for the formation of  $\text{NH}_3$  from  $\text{H}_2$  and 1 mol of  $\text{N}_2$ ? Explain and give the relationship between the two  $Q$ 's.

### Skill-Building Exercises (grouped in similar pairs)

**17.12** Balance each reaction and write its reaction quotient,  $Q_c$ :

**17.13** Balance each reaction and write its reaction quotient,  $Q_c$ :

**17.14** Balance each reaction and write its reaction quotient,  $Q_c$ :

**17.15** Balance each reaction and write its reaction quotient,  $Q_c$ :

- (a)  $O_2(g) \rightleftharpoons O_3(g)$   
 (b)  $NO(g) + O_3(g) \rightleftharpoons NO_2(g) + O_2(g)$   
 (c)  $N_2O(g) + H_2(g) \rightleftharpoons NH_3(g) + H_2O(g)$

**17.16** At a particular temperature,  $K_c = 1.6 \times 10^{-2}$  for

Calculate  $K_c$  for each of the following reactions:

- (a)  $\frac{1}{2}S_2(g) + H_2(g) \rightleftharpoons H_2S(g)$   
 (b)  $5H_2S(g) \rightleftharpoons 5H_2(g) + \frac{5}{2}S_2(g)$

**17.17** At a particular temperature,  $K_c = 6.5 \times 10^2$  for

Calculate  $K_c$  for each of the following reactions:

- (a)  $NO(g) + H_2(g) \rightleftharpoons \frac{1}{2}N_2(g) + H_2O(g)$   
 (b)  $2N_2(g) + 4H_2O(g) \rightleftharpoons 4NO(g) + 4H_2(g)$

**17.18** Balance each of the following examples of heterogeneous equilibria and write each reaction quotient,  $Q_c$ :

- (a)  $Na_2O_2(s) + CO_2(g) \rightleftharpoons Na_2CO_3(s) + O_2(g)$   
 (b)  $H_2O(l) \rightleftharpoons H_2O(g)$   
 (c)  $NH_4Cl(s) \rightleftharpoons NH_3(g) + HCl(g)$

**17.19** Balance each of the following examples of heterogeneous equilibria and write each reaction quotient,  $Q_c$ :

- (a)  $H_2O(l) + SO_3(g) \rightleftharpoons H_2SO_4(aq)$   
 (b)  $KNO_3(s) \rightleftharpoons KNO_2(s) + O_2(g)$   
 (c)  $S_8(s) + F_2(g) \rightleftharpoons SF_6(g)$

**17.20** Balance each of the following examples of heterogeneous equilibria and write each reaction quotient,  $Q_c$ :

- (a)  $NaHCO_3(s) \rightleftharpoons Na_2CO_3(s) + CO_2(g) + H_2O(g)$   
 (b)  $SnO_2(s) + H_2(g) \rightleftharpoons Sn(s) + H_2O(g)$   
 (c)  $H_2SO_4(l) + SO_3(g) \rightleftharpoons H_2S_2O_7(l)$

**17.21** Balance each of the following examples of heterogeneous equilibria and write each reaction quotient,  $Q_c$ :

- (a)  $Al(s) + NaOH(aq) + H_2O(l) \rightleftharpoons Na[Al(OH)_4](aq) + H_2(g)$   
 (b)  $CO_2(s) \rightleftharpoons CO_2(g)$   
 (c)  $N_2O_5(s) \rightleftharpoons NO_2(g) + O_2(g)$

### Problems in Context

**17.22** Write  $Q_c$  for each of the following:

- (a) Hydrogen chloride gas reacts with oxygen gas to produce chlorine gas and water vapor.  
 (b) Solid diarsenic trioxide reacts with fluorine gas to produce liquid arsenic pentafluoride and oxygen gas.  
 (c) Gaseous sulfur tetrafluoride reacts with liquid water to produce gaseous sulfur dioxide and hydrogen fluoride gas.  
 (d) Solid molybdenum(VI) oxide reacts with gaseous xenon difluoride to form liquid molybdenum(VI) fluoride, xenon gas, and oxygen gas.

**17.23** The interhalogen  $ClF_3$  is prepared via a two-step fluorination of chlorine gas:

- (a) Balance each step and write the overall equation.  
 (b) Show that the overall  $Q_c$  equals the product of the  $Q_c$ 's for the individual steps.

**17.24** As an EPA scientist studying catalytic converters and urban smog, you want to find  $K_c$  for the following reaction:

Use the following data to find the unknown  $K_c$ :

### Expressing Equilibria with Pressure Terms:

#### Relation Between $K_c$ and $K_p$

(Sample Problem 17.3)

### Concept Review Questions

**17.25** Guldberg and Waage proposed the definition of the equilibrium constant as a certain ratio of *concentrations*. What relationship allows us to use a particular ratio of *partial pressures* (for a gaseous reaction) to express an equilibrium constant? Explain.

**17.26** When are  $K_c$  and  $K_p$  equal, and when are they not?

**17.27** A certain reaction at equilibrium has more moles of gaseous products than of gaseous reactants.

- (a) Is  $K_c$  larger or smaller than  $K_p$ ?  
 (b) Write a statement about the relative sizes of  $K_c$  and  $K_p$  for any gaseous equilibrium.

### Skill-Building Exercises (grouped in similar pairs)

**17.28** Determine  $\Delta n_{\text{gas}}$  for each of the following reactions:

- (a)  $2KClO_3(s) \rightleftharpoons 2KCl(s) + 3O_2(g)$   
 (b)  $2PbO(s) + O_2(g) \rightleftharpoons 2PbO_2(s)$   
 (c)  $I_2(s) + 3XeF_2(s) \rightleftharpoons 2IF_3(s) + 3Xe(g)$

**17.29** Determine  $\Delta n_{\text{gas}}$  for each of the following reactions:

- (a)  $MgCO_3(s) \rightleftharpoons MgO(s) + CO_2(g)$   
 (b)  $2H_2(g) + O_2(g) \rightleftharpoons 2H_2O(l)$   
 (c)  $HNO_3(l) + ClF(g) \rightleftharpoons ClONO_2(g) + HF(g)$

**17.30** Calculate  $K_c$  for each of the following equilibria:

- (a)  $CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$ ;  $K_p = 3.9 \times 10^{-2}$  at 1000. K  
 (b)  $S_2(g) + C(s) \rightleftharpoons CS_2(g)$ ;  $K_p = 28.5$  at 500. K

**17.31** Calculate  $K_c$  for each of the following equilibria:

- (a)  $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$ ;  $K_p = 49$  at 730. K  
 (b)  $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$ ;  $K_p = 2.5 \times 10^{10}$  at 500. K

**17.32** Calculate  $K_p$  for each of the following equilibria:

- (a)  $N_2O_4(g) \rightleftharpoons 2NO_2(g)$ ;  $K_c = 6.1 \times 10^{-3}$  at 298 K  
 (b)  $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$ ;  $K_c = 2.4 \times 10^{-3}$  at 1000. K

**17.33** Calculate  $K_p$  for each of the following equilibria:

- (a)  $H_2(g) + CO_2(g) \rightleftharpoons H_2O(g) + CO(g)$ ;  $K_c = 0.77$  at 1020. K  
 (b)  $3O_2(g) \rightleftharpoons 2O_3(g)$ ;  $K_c = 1.8 \times 10^{-56}$  at 570. K

### Comparing $Q$ and $K$ to Determine Reaction Direction

(Sample Problems 17.4 and 17.5)

### Concept Review Questions

**17.34** When the numerical value of  $Q$  is less than that of  $K$ , in which direction does the reaction proceed to reach equilibrium? Explain.

**17.35** The following molecular scenes depict the aqueous reaction  $2D \rightleftharpoons E$ , with D *red* and E *blue*. Each sphere represents 0.0100 mol, but the volume is 1.00 L in scene A, whereas in scenes B and C, it is 0.500 L.

- (a) If the reaction in scene A is at equilibrium, calculate  $K_c$ .  
 (b) Are the reactions in scenes B and C at equilibrium? Which, if either, is not, and in which direction will it proceed?

### Skill-Building Exercises (grouped in similar pairs)

**17.36** At 425°C,  $K_p = 4.18 \times 10^{-9}$  for the reaction

In one experiment, 0.20 atm of  $\text{HBr}(g)$ , 0.010 atm of  $\text{H}_2(g)$ , and 0.010 atm of  $\text{Br}_2(g)$  are introduced into a container. Is the reaction at equilibrium? If not, in which direction will it proceed?

**17.37** At 100°C,  $K_p = 60.6$  for the reaction

In a given experiment, 0.10 atm of each component is placed in a container. Is the system at equilibrium? If not, in which direction will the reaction proceed?

### Problems in Context

**17.38** The water-gas shift reaction plays a central role in the chemical methods for obtaining cleaner fuels from coal:

At a given temperature,  $K_p = 2.7$ . If 0.13 mol of  $\text{CO}$ , 0.56 mol of  $\text{H}_2\text{O}$ , 0.62 mol of  $\text{CO}_2$ , and 0.43 mol of  $\text{H}_2$  are put in a 2.0-L flask, in which direction does the reaction proceed?

### How to Solve Equilibrium Problems

(Sample Problems 17.6 to 17.10)

### Concept Review Questions

**17.39** In the 1980s, CFC-11 was one of the most heavily produced chlorofluorocarbons. The last step in its formation is

If you start the reaction with equal concentrations of  $\text{CCl}_4$  and  $\text{HF}$ , you obtain equal concentrations of  $\text{CFCl}_3$  and  $\text{HCl}$  at equilibrium. Are the final concentrations of  $\text{CFCl}_3$  and  $\text{HCl}$  equal if you start with unequal concentrations of  $\text{CCl}_4$  and  $\text{HF}$ ? Explain.

**17.40** For a problem involving the catalyzed reaction of methane and steam, the following reaction table was prepared:

#### Pressure

(atm)	$\text{CH}_4(g)$	$+ 2\text{H}_2\text{O}(g)$	$\rightleftharpoons$	$\text{CO}_2(g)$	$+ 4\text{H}_2(g)$
Initial	0.30	0.40		0	0
Change	$-x$	$-2x$		$+x$	$+4x$
Equilibrium	$0.30 - x$	$0.40 - 2x$		$x$	$4x$

Explain the entries in the “Change” and “Equilibrium” rows.

**17.41** (a) What is the basis of the approximation that avoids the need to use the quadratic formula to find an equilibrium concentration?

(b) When should this approximation *not* be made?

### Skill-Building Exercises (grouped in similar pairs)

**17.42** In an experiment to study the formation of  $\text{HI}(g)$ ,

$\text{H}_2(g)$  and  $\text{I}_2(g)$  were placed in a sealed container at a certain temperature. At equilibrium,  $[\text{H}_2] = 6.50 \times 10^{-5} M$ ,  $[\text{I}_2] = 1.06 \times 10^{-3} M$ , and  $[\text{HI}] = 1.87 \times 10^{-3} M$ . Calculate  $K_c$  for the reaction at this temperature.

**17.43** Gaseous ammonia was introduced into a sealed container and heated to a certain temperature:

At equilibrium,  $[\text{NH}_3] = 0.0225 M$ ,  $[\text{N}_2] = 0.114 M$ , and  $[\text{H}_2] = 0.342 M$ . Calculate  $K_c$  for the reaction at this temperature.

**17.44** Gaseous  $\text{PCl}_5$  decomposes according to the reaction

In one experiment, 0.15 mol of  $\text{PCl}_5(g)$  was introduced into a 2.0-L container. Construct the reaction table for this process.

**17.45** Hydrogen fluoride,  $\text{HF}$ , can be made by the reaction

In one experiment, 0.10 mol of  $\text{H}_2(g)$  and 0.050 mol of  $\text{F}_2(g)$  are added to a 0.50-L flask. Write a reaction table for this process.

**17.46** For the following reaction,  $K_p = 6.5 \times 10^4$  at 308 K:

At equilibrium,  $P_{\text{NO}} = 0.35$  atm and  $P_{\text{Cl}_2} = 0.10$  atm. What is the equilibrium partial pressure of  $\text{NOCl}(g)$ ?

**17.47** For the following reaction,  $K_p = 0.262$  at 1000°C:

At equilibrium,  $P_{\text{H}_2}$  is 1.22 atm. What is the equilibrium partial pressure of  $\text{CH}_4(g)$ ?

**17.48** Ammonium hydrogen sulfide decomposes according to the following reaction, for which  $K_p = 0.11$  at 250°C:

If 55.0 g of  $\text{NH}_4\text{HS}(s)$  is placed in a sealed 5.0-L container, what is the partial pressure of  $\text{NH}_3(g)$  at equilibrium?

**17.49** Hydrogen sulfide decomposes according to the following reaction, for which  $K_c = 9.30 \times 10^{-8}$  at 700°C:

If 0.45 mol of  $\text{H}_2\text{S}$  is placed in a 3.0-L container, what is the equilibrium concentration of  $\text{H}_2(g)$  at 700°C?

**17.50** Even at high  $T$ , the formation of  $\text{NO}$  is not favored:

What is  $[\text{NO}]$  when a mixture of 0.20 mol of  $\text{N}_2(g)$  and 0.15 mol of  $\text{O}_2(g)$  reach equilibrium in a 1.0-L container at 2000°C?

**17.51** Nitrogen dioxide decomposes according to the reaction

where  $K_p = 4.48 \times 10^{-13}$  at a certain temperature. If 0.75 atm of  $\text{NO}_2$  is added to a container and allowed to come to equilibrium, what are the equilibrium partial pressures of  $\text{NO}(g)$  and  $\text{O}_2(g)$ ?

**17.52** Hydrogen iodide decomposes according to the reaction

A sealed 1.50-L container initially holds 0.00623 mol of  $\text{H}_2$ , 0.00414 mol of  $\text{I}_2$ , and 0.0244 mol of  $\text{HI}$  at 703 K. When equilibrium is reached, the concentration of  $\text{H}_2(g)$  is 0.00467 M. What are the concentrations of  $\text{HI}(g)$  and  $\text{I}_2(g)$ ?

**17.53** Compound A decomposes according to the equation

A sealed 1.00-L container initially contains  $1.75 \times 10^{-3}$  mol of  $\text{A}(g)$ ,  $1.25 \times 10^{-3}$  mol of  $\text{B}(g)$ , and  $6.50 \times 10^{-4}$  mol of  $\text{C}(g)$  at 100°C. At equilibrium,  $[\text{A}]$  is  $2.15 \times 10^{-3} M$ . Find  $[\text{B}]$  and  $[\text{C}]$ .

### Problems in Context

**17.54** In an analysis of interhalogen reactivity, 0.500 mol of  $\text{ICl}$  was placed in a 5.00-L flask, where it decomposed at a high  $T$ :

Calculate the equilibrium concentrations of  $\text{I}_2$ ,  $\text{Cl}_2$ , and  $\text{ICl}$  ( $K_c = 0.110$  at this temperature).

**17.55** A toxicologist studying mustard gas,  $S(CH_2CH_2Cl)_2$ , a blistering agent, prepares a mixture of  $0.675\text{ M } SCl_2$  and  $0.973\text{ M } C_2H_4$  and allows it to react at room temperature ( $20.0^\circ\text{C}$ ):

At equilibrium,  $[S(CH_2CH_2Cl)_2] = 0.350\text{ M}$ . Calculate  $K_p$ .

**17.56** The first step in  $HNO_3$  production is the catalyzed oxidation of  $NH_3$ . Without a catalyst, a different reaction predominates:

When  $0.0150\text{ mol}$  of  $NH_3(g)$  and  $0.0150\text{ mol}$  of  $O_2(g)$  are placed in a  $1.00\text{-L}$  container at a certain temperature, the  $N_2$  concentration at equilibrium is  $1.96 \times 10^{-3}\text{ M}$ . Calculate  $K_c$ .

**17.57** A key step in the extraction of iron from its ore is

$FeO(s) + CO(g) \rightleftharpoons Fe(s) + CO_2(g)$   $K_p = 0.403$  at  $1000^\circ\text{C}$   
This step occurs in the  $700^\circ\text{C}$  to  $1200^\circ\text{C}$  zone within a blast furnace. What are the equilibrium partial pressures of  $CO(g)$  and  $CO_2(g)$  when  $1.00\text{ atm}$  of  $CO(g)$  and excess  $FeO(s)$  react in a sealed container at  $1000^\circ\text{C}$ ?

### Reaction Conditions and Equilibrium: Le Châtelier's Principle (Sample Problems 17.11 to 17.14)

#### Concept Review Questions

**17.58** What does “disturbance” mean in Le Châtelier's principle?

**17.59** What is the difference between the equilibrium position and the equilibrium constant of a reaction? Which changes as a result of a change in reactant concentration?

**17.60** Scenes A, B, and C below depict the following reaction at three temperatures:

(a) Which best represents the reaction mixture at the highest temperature? Explain. (b) Which best represents the reaction mixture at the lowest temperature? Explain.

**17.61** What is implied by the word “constant” in the term *equilibrium constant*? Give two reaction parameters that can be changed without changing the value of an equilibrium constant.

**17.62** Le Châtelier's principle is related ultimately to the rates of the forward and reverse steps in a reaction. Explain (a) why an increase in reactant concentration shifts the equilibrium position to the right but does not change  $K$ ; (b) why a decrease in  $V$  shifts the equilibrium position toward fewer moles of gas but does not change  $K$ ; (c) why a rise in  $T$  shifts the equilibrium position of an exothermic reaction toward reactants and also changes  $K$ ; and (d) why a rise in temperature of an endothermic reaction from  $T_1$  to  $T_2$  results in  $K_2$  being larger than  $K_1$ .

**17.63** An equilibrium mixture of two solids and a gas, in the reaction  $XY(s) \rightleftharpoons X(g) + Y(s)$ , is depicted at right ( $X$  is green and  $Y$  is black). Does scene A, B, or C best represent the system at equilibrium after two formula units of  $Y(s)$  is added? Explain.

#### Skill-Building Exercises (grouped in similar pairs)

**17.64** Consider this equilibrium system:

How does the equilibrium position shift as a result of each of the following disturbances? (a)  $CO$  is added. (b)  $CO_2$  is removed by adding solid  $NaOH$ . (c) Additional  $Fe_3O_4(s)$  is added to the system. (d) Dry ice is added at constant temperature.

**17.65** Sodium bicarbonate undergoes thermal decomposition according to the reaction

How does the equilibrium position shift as a result of each of the following disturbances? (a)  $0.20\text{ atm}$  of argon gas is added. (b)  $NaHCO_3(s)$  is added. (c)  $Mg(ClO_4)_2(s)$  is added as a drying agent to remove  $H_2O$ . (d) Dry ice is added at constant  $T$ .

**17.66** Predict the effect of *increasing* the container volume on the amounts of each reactant and product in the following reactions:

**17.67** Predict the effect of *increasing* the container volume on the amounts of each reactant and product in the following reactions:

**17.68** Predict the effect of *decreasing* the container volume on the amounts of each reactant and product in the following reactions:

**17.69** Predict the effect of *decreasing* the container volume on the amounts of each reactant and product in the following reactions:

**17.70** How would you adjust the *volume* of the container in order to maximize product yield in each of the following reactions?

**17.71** How would you adjust the *volume* of the container in order to maximize product yield in each of the following reactions?

**17.72** Predict the effect of *increasing* the temperature on the amount(s) of product(s) in the following reactions:

**17.73** Predict the effect of *decreasing* the temperature on the amount(s) of reactant(s) in the following reactions:

**17.74** The molecule  $\text{D}_2$  (where D, deuterium, is  $^2\text{H}$ ) undergoes a reaction with ordinary  $\text{H}_2$  that leads to isotopic equilibrium:

If  $\Delta H_{\text{rxn}}^\circ$  is 0.32 kJ/mol DH, calculate  $K_p$  at 500. K.

**17.75** The formation of methanol is important to the processing of new fuels. At 298 K,  $K_p = 2.25 \times 10^4$  for the reaction

If  $\Delta H_{\text{rxn}}^\circ = -128$  kJ/mol  $\text{CH}_3\text{OH}$ , calculate  $K_p$  at  $0^\circ\text{C}$ .

### Problems in Context

**17.76** The minerals hematite ( $\text{Fe}_2\text{O}_3$ ) and magnetite ( $\text{Fe}_3\text{O}_4$ ) exist in equilibrium with atmospheric oxygen:

(a) Determine  $P_{\text{O}_2}$  at equilibrium. (b) Given that  $P_{\text{O}_2}$  in air is 0.21 atm, in which direction will the reaction proceed to reach equilibrium? (c) Calculate  $K_c$  at 298 K.

**17.77** The oxidation of  $\text{SO}_2$  is the key step in  $\text{H}_2\text{SO}_4$  production:

(a) What qualitative combination of  $T$  and  $P$  maximizes  $\text{SO}_3$  yield? (b) How does addition of  $\text{O}_2$  affect  $Q$ ?  $K$ ? (c) Why is catalysis used for this reaction?

**17.78** A mixture of 3.00 volumes of  $\text{H}_2$  and 1.00 volume of  $\text{N}_2$  reacts at  $344^\circ\text{C}$  to form ammonia. The equilibrium mixture at 110. atm contains 41.49%  $\text{NH}_3$  by volume. Calculate  $K_p$  for the reaction, assuming that the gases behave ideally.

**17.79** You are a member of a research team of chemists discussing plans for a plant to produce ammonia:

(a) The plant will operate at close to 700 K, at which  $K_p$  is  $1.00 \times 10^{-4}$ , and employs the stoichiometric 1/3 ratio of  $\text{N}_2/\text{H}_2$ . At equilibrium, the partial pressure of  $\text{NH}_3$  is 50. atm. Calculate the partial pressures of each reactant and  $P_{\text{total}}$ .

(b) One member of the team suggests the following: since the partial pressure of  $\text{H}_2$  is cubed in the reaction quotient, the plant could produce the same amount of  $\text{NH}_3$  if the reactants were in a 1/6 ratio of  $\text{N}_2/\text{H}_2$  and could do so at a lower pressure, which would cut operating costs. Calculate the partial pressure of each reactant and  $P_{\text{total}}$  under these conditions, assuming an unchanged partial pressure of 50. atm for  $\text{NH}_3$ . Is the suggestion valid?

### Comprehensive Problems

**17.80** For the following equilibrium system, which of the changes will form more  $\text{CaCO}_3$ ?

$$\Delta H^\circ = -113 \text{ kJ}$$

- (a) Decrease temperature at constant pressure (no phase change)  
 (b) Increase volume at constant temperature  
 (c) Increase partial pressure of  $\text{CO}_2$   
 (d) Remove one-half of the initial  $\text{CaCO}_3$

**17.81** The “filmstrip” represents five molecular scenes of a gaseous mixture as it reaches equilibrium over time:

$X$  is purple and  $Y$  is orange:  $X_2(g) + Y_2(g) \rightleftharpoons 2XY(g)$ .

- (a) Write the reaction quotient,  $Q$ , for this reaction.  
 (b) If each particle represents 0.1 mol, find  $Q$  for each scene.  
 (c) If  $K > 1$ , is time progressing to the right or to the left? Explain.  
 (d) Calculate  $K$  at this temperature.  
 (e) If  $\Delta H_{\text{rxn}}^\circ < 0$ , which scene, if any, best represents the mixture at a higher temperature? Explain.  
 (f) Which scene, if any, best represents the mixture at a higher pressure (lower volume)? Explain.

**17.82** Ammonium carbamate ( $\text{NH}_2\text{COONH}_4$ ) is a salt of carbamic acid that is found in the blood and urine of mammals. At  $250.^\circ\text{C}$ ,  $K_c = 1.58 \times 10^{-8}$  for the following equilibrium:

If 7.80 g of  $\text{NH}_2\text{COONH}_4$  is put into a 0.500-L evacuated container, what is the total pressure at equilibrium?

**17.83** Isolation of Group 8B(10) elements, used as industrial catalysts, involves a series of steps. For nickel, the sulfide ore is roasted in air:  $\text{Ni}_3\text{S}_2(s) + \text{O}_2(g) \rightleftharpoons \text{NiO}(s) + \text{SO}_2(g)$ . The metal oxide is reduced by the  $\text{H}_2$  in water gas ( $\text{CO} + \text{H}_2$ ) to impure Ni:  $\text{NiO}(s) + \text{H}_2(g) \rightleftharpoons \text{Ni}(s) + \text{H}_2\text{O}(g)$ . The CO in water gas then reacts with the metal in the Mond process to form gaseous nickel carbonyl,  $\text{Ni}(s) + \text{CO}(g) \rightleftharpoons \text{Ni}(\text{CO})_4(g)$ , which is subsequently decomposed to the metal. (a) Balance each of the three steps, and obtain an overall balanced equation for the conversion of  $\text{Ni}_3\text{S}_2$  to  $\text{Ni}(\text{CO})_4$ . (b) Show that the overall  $Q_c$  is the product of the  $Q_c$ 's for the individual reactions.

**17.84** Consider the formation of ammonia in two experiments.

(a) To a 1.00-L container at  $727^\circ\text{C}$ , 1.30 mol of  $\text{N}_2$  and 1.65 mol of  $\text{H}_2$  are added. At equilibrium, 0.100 mol of  $\text{NH}_3$  is present. Calculate the equilibrium concentrations of  $\text{N}_2$  and  $\text{H}_2$ , and find  $K_c$  for the reaction:

(b) In a different 1.00-L container at the same temperature, equilibrium is established with  $8.34 \times 10^{-2}$  mol of  $\text{NH}_3$ , 1.50 mol of  $\text{N}_2$ , and 1.25 mol of  $\text{H}_2$  present. Calculate  $K_c$  for the reaction:

(c) What is the relationship between the  $K_c$  values in parts (a) and (b)? Why aren't these values the same?

**17.85** An important industrial source of ethanol is the reaction, catalyzed by  $\text{H}_3\text{PO}_4$ , of steam with ethylene derived from oil:

$$\Delta H_{\text{rxn}}^\circ = -47.8 \text{ kJ} \quad K_c = 9 \times 10^3 \text{ at } 600. \text{ K}$$

(a) At equilibrium,  $P_{\text{C}_2\text{H}_5\text{OH}} = 200.$  atm and  $P_{\text{H}_2\text{O}} = 400.$  atm. Calculate  $P_{\text{C}_2\text{H}_4}$ . (b) Is the highest yield of ethanol obtained at high or low  $P$ ? High or low  $T$ ? (c) Calculate  $K_c$  at 450. K. (d) In  $\text{NH}_3$  manufacture, the yield is increased by condensing the  $\text{NH}_3$  to a liquid and removing it. Would condensing the  $\text{C}_2\text{H}_5\text{OH}$  have the same effect in ethanol production? Explain.

**17.86** An industrial chemist introduces 2.0 atm of  $\text{H}_2$  and 2.0 atm of  $\text{CO}_2$  into a 1.00-L container at  $25.0^\circ\text{C}$  and then raises the temperature to  $700.^\circ\text{C}$ , at which  $K_c = 0.534$ :

How many grams of  $\text{H}_2$  are present at equilibrium?

**17.87** An engineer examining the oxidation of  $\text{SO}_2$  in the manufacture of sulfuric acid determines that  $K_c = 1.7 \times 10^8$  at 600. K:

(a) At equilibrium,  $P_{\text{SO}_3} = 300.$  atm and  $P_{\text{O}_2} = 100.$  atm. Calculate  $P_{\text{SO}_2}$ . (b) The engineer places a mixture of 0.0040 mol of  $\text{SO}_2(g)$  and 0.0028 mol of  $\text{O}_2(g)$  in a 1.0-L container and raises the temperature to 1000 K. At equilibrium, 0.0020 mol of  $\text{SO}_3(g)$  is present. Calculate  $K_c$  and  $P_{\text{SO}_2}$  for this reaction at 1000. K.

**17.88** Phosgene ( $\text{COCl}_2$ ) is a toxic substance that forms readily from carbon monoxide and chlorine at elevated temperatures:

If 0.350 mol of each reactant is placed in a 0.500-L flask at 600 K, what are the concentrations of all three substances at equilibrium ( $K_c = 4.95$  at this temperature)?

**17.89** When 0.100 mol of  $\text{CaCO}_3(s)$  and 0.100 mol of  $\text{CaO}(s)$  are placed in an evacuated sealed 10.0-L container and heated to 385 K,  $P_{\text{CO}_2} = 0.220$  atm after equilibrium is established:

An additional 0.300 atm of  $\text{CO}_2(g)$  is pumped in. What is the total mass (in g) of  $\text{CaCO}_3$  after equilibrium is re-established?

**17.90** Use each of the following reaction quotients to write the balanced equation:

$$(a) \quad Q = \frac{[\text{CO}_2]^2[\text{H}_2\text{O}]^2}{[\text{C}_2\text{H}_4][\text{O}_2]^3} \quad (b) \quad Q = \frac{[\text{NH}_3]^4[\text{O}_2]^7}{[\text{NO}_2]^4[\text{H}_2\text{O}]^6}$$

**17.91** Hydrogenation of carbon-carbon  $\pi$  bonds is important in the petroleum and food industries. The conversion of acetylene to ethylene is a simple example of the process:

The calculated  $K_c$  at 2000. K is  $2.9 \times 10^8$ . But the process is run at lower temperatures with the aid of a catalyst to prevent decomposition. Use  $\Delta H^\circ$  values to calculate  $K_c$  at 300. K.

**17.92** For the reaction  $\text{M}_2 + \text{N}_2 \rightleftharpoons 2\text{MN}$ , scene A represents the mixture at equilibrium, with M *black* and N *orange*. If each molecule represents 0.10 mol and the volume is 1.0 L, how many moles of each substance will be present in scene B when that mixture reaches equilibrium?

**17.93** Highly toxic disulfur decafluoride decomposes by a free-radical process:  $\text{S}_2\text{F}_{10}(g) \rightleftharpoons \text{SF}_4(g) + \text{SF}_6(g)$ . In a study of the decomposition,  $\text{S}_2\text{F}_{10}$  was placed in a 2.0-L flask and heated to  $100^\circ\text{C}$ ;  $[\text{S}_2\text{F}_{10}]$  was 0.50 M at equilibrium. More  $\text{S}_2\text{F}_{10}$  was added, and when equilibrium was reattained,  $[\text{S}_2\text{F}_{10}]$  was 2.5 M. How did  $[\text{SF}_4]$  and  $[\text{SF}_6]$  change from the original to the new equilibrium position after the addition of more  $\text{S}_2\text{F}_{10}$ ?

**17.94** A study of the water-gas shift reaction (see Problem 17.38) was made in which equilibrium was reached with  $[\text{CO}] = [\text{H}_2\text{O}] = [\text{H}_2] = 0.10$  M and  $[\text{CO}_2] = 0.40$  M. After 0.60 mol of  $\text{H}_2$  is added to the 2.0-L container and equilibrium is re-established, what are the new concentrations of all the components?

**17.95** A gaseous mixture of 10.0 volumes of  $\text{CO}_2$ , 1.00 volume of unreacted  $\text{O}_2$ , and 50.0 volumes of unreacted  $\text{N}_2$  leaves an engine at 4.0 atm and 800. K. Assuming that the mixture reaches equilibrium, what are (a) the partial pressure and (b) the concentration (in picograms per liter, pg/L) of CO in this exhaust gas?

(The actual concentration of CO in exhaust gas is much higher because the gases do *not* reach equilibrium in the short transit time through the engine and exhaust system.)

**17.96** When ammonia is made industrially, the mixture of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$  that emerges from the reaction chamber is far from equilibrium. Why does the plant supervisor use reaction conditions that produce less than the maximum yield of ammonia?

**17.97** The following reaction can be used to make  $\text{H}_2$  for the synthesis of ammonia from the greenhouse gases carbon dioxide and methane:

(a) What is the percent yield of  $\text{H}_2$  when an equimolar mixture of  $\text{CH}_4$  and  $\text{CO}_2$  with a total pressure of 20.0 atm reaches equilibrium at 1200. K, at which  $K_p = 3.548 \times 10^6$ ?

(b) What is the percent yield of  $\text{H}_2$  for this system at 1300. K, at which  $K_p = 2.626 \times 10^7$ ?

(c) Use the van't Hoff equation to find  $\Delta H_{\text{rxn}}^\circ$ .

**17.98** The methane used to obtain  $\text{H}_2$  for  $\text{NH}_3$  manufacture is impure and usually contains other hydrocarbons, such as propane,  $\text{C}_3\text{H}_8$ . Imagine the reaction of propane occurring in two steps:

(a) Write the overall equation for the reaction of propane and steam to produce carbon dioxide and hydrogen.

(b) Calculate  $K_p$  for the overall process at 1200. K.

(c) When 1.00 volume of  $\text{C}_3\text{H}_8$  and 4.00 volumes of  $\text{H}_2\text{O}$ , each at 1200. K and 5.0 atm, are mixed in a container, what is the final pressure? Assume the total volume remains constant, that the reaction is essentially complete, and that the gases behave ideally.

(d) What percentage of the  $\text{C}_3\text{H}_8$  remains unreacted?

**17.99** Using  $\text{CH}_4$  and steam as a source of  $\text{H}_2$  for  $\text{NH}_3$  synthesis requires high temperatures. Rather than burning  $\text{CH}_4$  separately to heat the mixture, it is more efficient to inject some  $\text{O}_2$  into the reaction mixture. All of the  $\text{H}_2$  is thus released for the synthesis, and the heat of reaction for the combustion of  $\text{CH}_4$  helps maintain the required temperature. Imagine the reaction occurring in two steps:

(a) Write the overall equation for the reaction of methane, steam, and oxygen to form carbon dioxide and hydrogen.

(b) What is  $K_p$  for the overall reaction?

(c) What is  $K_c$  for the overall reaction?

(d) A mixture of 2.0 mol of  $\text{CH}_4$ , 1.0 mol of  $\text{O}_2$ , and 2.0 mol of steam with a total pressure of 30. atm reacts at 1000. K at constant volume. Assuming that the reaction is complete and the ideal gas law is a valid approximation, what is the final pressure?

**17.100** One mechanism for the synthesis of ammonia proposes that  $\text{N}_2$  and  $\text{H}_2$  molecules catalytically dissociate into atoms:

- (a) Find the partial pressure of N in  $\text{N}_2$  at 1000. K and 200. atm.  
 (b) Find the partial pressure of H in  $\text{H}_2$  at 1000. K and 600. atm.  
 (c) How many N atoms and H atoms are present per liter?  
 (d) Based on these answers, which of the following is a more reasonable step to continue the mechanism after the catalytic dissociation? Explain.

**17.101** The molecular scenes below depict the reaction  $\text{Y} \rightleftharpoons 2\text{Z}$  at four different times, out of sequence, as it reaches equilibrium. Each sphere (Y is red and Z is green) represents 0.025 mol, and the volume is 0.40 L. (a) Which scene(s) represent(s) equilibrium? (b) List the scenes in the correct sequence. (c) Calculate  $K_c$ .

**17.102** For the equilibrium

the initial concentrations of the three gases are 0.300 M  $\text{H}_2\text{S}$ , 0.300 M  $\text{H}_2$ , and 0.150 M  $\text{S}_2$ . Determine the equilibrium concentrations of the gases.

**17.103** The two most abundant atmospheric gases react to a tiny extent at 298 K in the presence of a catalyst:

- (a) What are the equilibrium pressures of the three gases when the atmospheric partial pressures of  $\text{O}_2$  (0.210 atm) and of  $\text{N}_2$  (0.780 atm) are put into an evacuated 1.00-L flask at 298 K with the catalyst?  
 (b) What is  $P_{\text{total}}$  in the container? (c) Find  $K_c$  at 298 K.

**17.104** The oxidation of nitrogen monoxide is favored at 457 K:

- (a) Calculate  $K_c$  at 457 K. (b) Find  $\Delta H_{\text{rxn}}^\circ$  from standard heats of formation. (c) At what temperature does  $K_c = 6.4 \times 10^9$ ?

**17.105** The kinetics and equilibrium of the decomposition of hydrogen iodide have been studied extensively:

- (a) At 298 K,  $K_c = 1.26 \times 10^{-3}$  for this reaction. Calculate  $K_p$ .  
 (b) Calculate  $K_c$  for the formation of HI at 298 K.

(c) Calculate  $\Delta H_{\text{rxn}}^\circ$  for HI decomposition from  $\Delta H_f^\circ$  values.

(d) At 729 K,  $K_c = 2.0 \times 10^{-2}$  for HI decomposition. Calculate  $\Delta H_{\text{rxn}}^\circ$  for this reaction from the van't Hoff equation.

**17.106** Isopentyl alcohol reacts with pure acetic acid to form isopentyl acetate, the essence of banana oil:

A student adds a drying agent to remove  $\text{H}_2\text{O}$  and thus increase the yield of banana oil. Is this approach reasonable? Explain.

**17.107** Isomers Q (blue) and R (yellow) interconvert. They are depicted in an equilibrium mixture in scene A. Scene B represents the mixture after addition of more Q. How many molecules of each isomer are present when the mixture in scene B attains equilibrium again?

**17.108** Glauber's salt,  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ , was used by J. R. Glauber in the 17<sup>th</sup> century as a medicinal agent. At 25°C,  $K_p = 4.08 \times 10^{-25}$  for the loss of waters of hydration from Glauber's salt:

- (a) What is the vapor pressure of water at 25°C in a closed container holding a sample of  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}(s)$ ?  
 (b) How do the following changes affect the ratio (higher, lower, same) of hydrated form to anhydrous form for the system above?  
 (1) Add more  $\text{Na}_2\text{SO}_4(s)$   
 (2) Reduce the container volume  
 (3) Add more water vapor  
 (4) Add  $\text{N}_2$  gas

**17.109** In a study of synthetic fuels, 0.100 mol of CO and 0.100 mol of water vapor are added to a 20.00-L container at 900.°C, and they react to form  $\text{CO}_2$  and  $\text{H}_2$ . At equilibrium,  $[\text{CO}]$  is  $2.24 \times 10^{-3}$  M. (a) Calculate  $K_c$  at this temperature. (b) Calculate  $P_{\text{total}}$  in the flask at equilibrium. (c) How many moles of CO must be added to double this pressure? (d) After  $P_{\text{total}}$  is doubled and the system reattains equilibrium, what is  $[\text{CO}]_{\text{eq}}$ ?

**17.110** Synthetic diamonds are made under conditions of high temperature (2000 K) and high pressure ( $10^{10}$  Pa;  $10^5$  atm) in the presence of catalysts. Carbon's phase diagram is useful for finding the conditions for formation of natural and synthetic diamonds. Along the diamond-graphite line, the two allotropes are in equilibrium. (a) At point A, what is the sign of  $\Delta H$  for the formation of diamond from graphite? Explain. (b) Which allotrope is denser? Explain.

## Concepts and Skills to Review Before You Study This Chapter

- › role of water as solvent (Section 4.1)
- › writing ionic equations (Section 4.2)
- › acids, bases, and acid-base reactions (Section 4.4)
- › proton transfer in acid-base reactions (Section 4.4)
- › properties of an equilibrium constant (Section 17.2)
- › solving equilibrium problems (Section 17.5)

**I**t's lunch time: how about a meal of citric and ascorbic acids (lemons and oranges), oxalic acid (spinach), folic acid (broccoli), and lactic acid (yogurt), all washed down with some phosphoric acid (soft drink)—if you eat too much, you may need some magnesium or aluminum hydroxide base (antacid)! Acids and bases are in many common consumer products (Table 18.1) and are indispensable in academic and industrial research.

Acids gives substances such as lemon juice and vinegar a sour taste. In fact, sourness was a defining property of an acid since the 17<sup>th</sup> century: an acid was any substance that had a sour taste; reacted with active metals, such as aluminum and zinc, to produce hydrogen gas; and turned certain organic compounds specific colors. (We discuss *indicators* in this chapter and Chapter 19.) Similarly, a base was any substance that had a bitter taste and slippery feel and turned the same organic compounds different colors. Moreover, it was known that *when an acid and a base react, each cancels the properties of the other in a process called neutralization*. Although these early definitions described distinctive properties, they gave way to others based on molecular behavior. As science progresses, limited definitions are replaced by broader ones that explain more phenomena.

Table 18.1

Some Common Acids and Bases and Their Household Uses

Substance	Use
<b>Acids</b>	
Acetic acid, $\text{CH}_3\text{COOH}$	Flavoring, preservative (vinegar)
Citric acid, $\text{H}_3\text{C}_6\text{H}_5\text{O}_7$	Flavoring (lemon juice)
Ascorbic acid, $\text{H}_2\text{C}_6\text{H}_6\text{O}_6$	Vitamin C; nutritional supplement
Aluminum salts, $\text{NaAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$	In baking powder, with sodium hydrogen carbonate
<b>Bases</b>	
Sodium hydroxide (lye), $\text{NaOH}$	Oven and drain cleaners
Ammonia, $\text{NH}_3$	Household cleaner
Sodium carbonate, $\text{Na}_2\text{CO}_3$	Water softener, grease remover
Sodium hydrogen carbonate, $\text{NaHCO}_3$	Fire extinguisher, rising agent in cake mixes (baking soda), mild antacid
Sodium phosphate, $\text{Na}_3\text{PO}_4$	Cleaner for surfaces before painting or wallpapering

**IN THIS CHAPTER . . .** We develop three definitions of acids and bases that explain an expanded range of reactions, and we apply equilibrium principles to understand acid-base behavior.

- › We begin with the *Arrhenius* acid-base definition, which relies on formulas and behavior in water.
- › We examine acid dissociation to see how variation in acid strength is expressed by a new equilibrium constant.
- › We introduce the pH scale to measure the acidity of aqueous solutions.
- › We discuss proton transfer in the *Bronsted-Lowry* acid-base definition, which expands the meaning of “base”, along with the scope of acid-base reactions.
- › We apply a systematic approach to solving acid-base equilibrium problems.
- › We examine the molecular structures of acids to rationalize their relative strengths.

- › We examine weak bases and their interdependence with weak acids.
- › We determine the relative acidity of salt solutions from the reactions of the salts' cations and anions with water.
- › We see that the designations “acid” and “base” depend on the substances' relative strengths *and* on the solvent.
- › We discuss the *Lewis* acid-base definition, which greatly expands the meanings of “acid” and “acid-base reaction”.

## 18.1 ACIDS AND BASES IN WATER

Most laboratory work with acids and bases involves water, as do most environmental, biological, and industrial applications. Recall from our discussion in Chapter 4 that *water is the product in all reactions between strong acids and strong bases*, which the net ionic equation for any such reaction shows:

where  $\text{M}^+$  is a metal ion and  $\text{X}^-$  is a nonmetal ion.

Furthermore, whenever an acid dissociates in water, solvent molecules participate in the reaction:

Water molecules surround the proton to form H-bonded species with the general formula  $(\text{H}_2\text{O})_n\text{H}^+$ . The proton's charge density is so high that it attracts water molecules especially strongly, covalently bonding to one of the lone electron pairs of a water molecule's O atom to form a **hydronium ion,  $\text{H}_3\text{O}^+$** , which forms H bonds to several other water molecules (see Figure 4.11). To emphasize the active role of water and the proton-water interaction, the hydrated proton is usually shown in the text as  $\text{H}_3\text{O}^+(aq)$  [although, for simplicity, we sometimes show it as  $\text{H}^+(aq)$ ].

### Release of $\text{H}^+$ or $\text{OH}^-$ and the Arrhenius Acid-Base Definition

The earliest definition that highlighted the molecular nature of acids and bases is the **Arrhenius acid-base definition**, which classifies these substances in terms of their formulas and behavior *in water*:

- An *acid* is a substance with H in its formula that dissociates in water to yield  $\text{H}_3\text{O}^+$ .
- A *base* is a substance with OH in its formula that dissociates in water to yield  $\text{OH}^-$ .

Some typical Arrhenius acids are HCl,  $\text{HNO}_3$ , and HCN, and some typical Arrhenius bases are NaOH, KOH, and  $\text{Ba}(\text{OH})_2$ . Because they are ionic compounds, Arrhenius bases contain discrete  $\text{OH}^-$  ions in their structures, but Arrhenius acids *never* contain discrete  $\text{H}^+$  ions. Instead, they contain *covalently bonded H atoms that ionize when molecules of the acid dissolve in water*.

When an acid and a base react, they undergo **neutralization**. The meaning of this term has changed, as we'll see, but in the Arrhenius sense, neutralization occurs when *the  $\text{H}^+$  from the acid and the  $\text{OH}^-$  from the base form  $\text{H}_2\text{O}$* . A key point about neutralization that Arrhenius was able to explain is that no matter which strong acid and strong base react, and no matter which salt results,  $\Delta H_{\text{rxn}}^\circ$  is  $-55.9$  kJ per mole of water formed. Arrhenius suggested that the enthalpy change is always the same because the reaction is always the same—a hydrogen ion and a hydroxide ion form water:

The dissolved salt that is present, for example, NaCl in the reaction of sodium hydroxide with hydrochloric acid,

exists as hydrated spectator ions and does not affect  $\Delta H_{\text{rxn}}^\circ$ .

Despite its importance at the time, limitations in the Arrhenius definition soon became apparent. Arrhenius and many others realized that even though some substances do *not* have discrete  $\text{OH}^-$  ions, they still behave as bases. For example,  $\text{NH}_3$  and  $\text{K}_2\text{CO}_3$  also yield  $\text{OH}^-$  in water. As you'll see shortly, broader acid-base definitions are required to include species that do not have  $\text{OH}^-$  ions in their structures.

### Variation in Acid Strength: The Acid-Dissociation Constant ( $K_a$ )

Acids (and bases) are classified by their *strength*, the amount of  $\text{H}_3\text{O}^+$  (or  $\text{OH}^-$ ) produced per mole of substance dissolved, in other words, by the extent of their dissociation into ions (see Table 4.2). Because acids and bases are electrolytes, their strength correlates with electrolyte strength: *strong electrolytes dissociate completely, and weak electrolytes dissociate slightly.*

1. *Strong acids dissociate **completely** into ions in water* (Figure 18.1A):

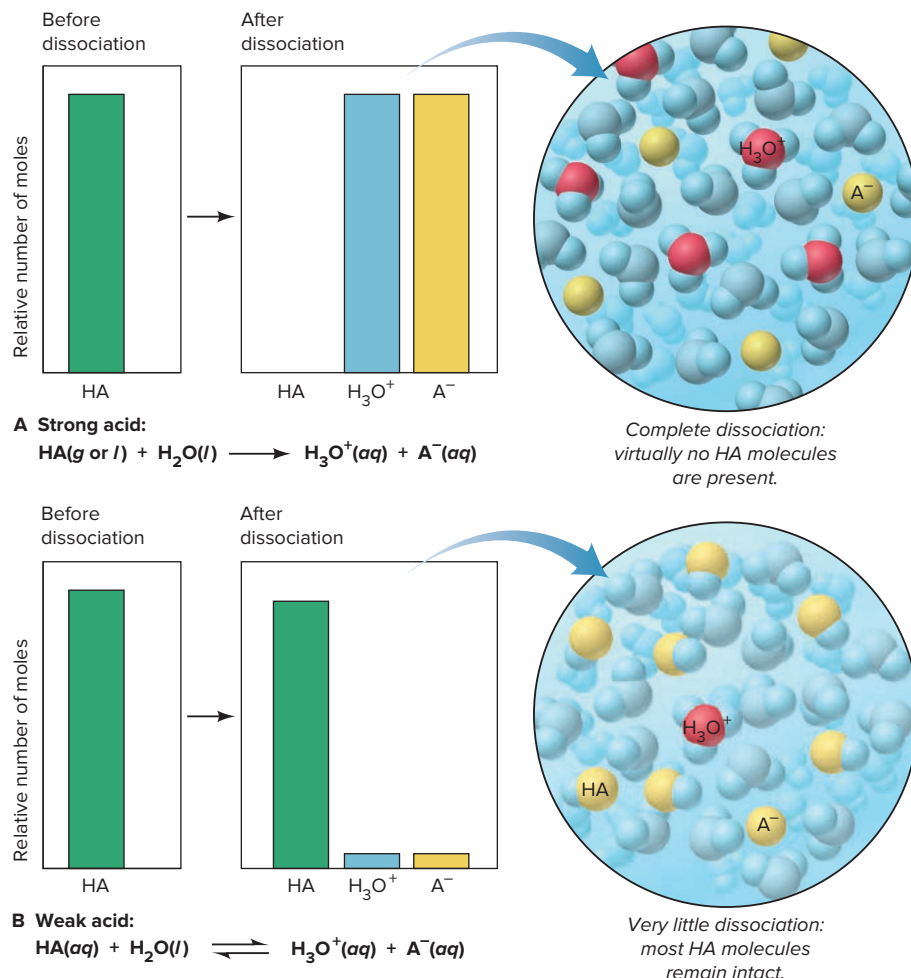

In a dilute solution of a strong acid, *HA molecules are no longer present*:  $[\text{H}_3\text{O}^+] = [\text{A}^-] \approx [\text{HA}]_{\text{init}}$ . In other words,  $[\text{HA}]_{\text{eq}} \approx 0$ , so the value of  $K_c$  is extremely large:

$$Q_c = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}][\text{H}_2\text{O}]} \quad (\text{at equilibrium, } Q_c = K_c \gg 1)$$

Because the reaction is essentially complete, we usually don't express it as an equilibrium process. In dilute aqueous nitric acid, for example, there are virtually no undissociated nitric acid molecules:

2. *Weak acids dissociate **slightly** into ions in water* (Figure 18.1B):

**Figure 18.1** The extent of dissociation for strong acids and weak acids. The bar graphs show the relative numbers of moles of species before (*left*) and after (*right*) acid dissociation.

In a dilute solution of a weak acid, *the great majority of HA molecules are undissociated*. Thus,  $[H_3O^+] = [A^-] \ll [HA]_{\text{init}}$ , and  $[HA]_{\text{eq}} \approx [HA]_{\text{init}}$ , so  $K_c$  is very small. Hydrocyanic acid is an example of a weak acid:

(As in Chapter 17, brackets with no subscript mean molar concentration *at equilibrium*; that is,  $[X]$  means  $[X]_{\text{eq}}$ . In this chapter, we are dealing with systems *at equilibrium*, so instead of writing  $Q$  and stating that  $Q$  equals  $K$  at equilibrium, we'll express  $K$  directly as a collection of equilibrium concentration terms.)

The difference in  $[H_3O^+]$  causes a much higher rate for the reaction of a strong acid with an active metal like zinc than for the same reaction of a weak acid (Figure 18.2):

In a strong acid, with its much higher  $[H_3O^+]$ , zinc reacts rapidly, forming bubbles of  $\text{H}_2$  vigorously. In a weak acid,  $[H_3O^+]$  is much lower, so zinc reacts slowly.

**The Meaning of  $K_a$**  We write a *specific* equilibrium constant for acid dissociation that includes only the species whose concentrations change to any significant extent. For the dissociation of a general *weak acid*, HA,

the equilibrium expression is

$$K_c = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}][\text{H}_2\text{O}]}$$

The concentration of water ( $[\text{H}_2\text{O}] = \frac{1000 \text{ g}}{18.02 \text{ g/mol}} = 55.5 \text{ M}$ ) is typically several

orders of magnitude larger than  $[\text{HA}]$ . Therefore,  $[\text{H}_2\text{O}]$  is essentially constant when HA dissociates, and so  $\text{H}_2\text{O}$  can be considered a pure liquid. As we discussed in Section 17.2, the concentration terms for pure liquids and solids are equal to 1 and do not appear in the equilibrium expression. Thus, we can define a new equilibrium constant, the **acid-dissociation constant (or acid-ionization constant),  $K_a$** :

$$K_c \times 1 = K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} \quad (18.1)$$

Like any equilibrium constant,  $K_a$  is a number whose magnitude is temperature dependent and tells how far to the right the reaction has proceeded to reach equilibrium. Thus, *the stronger the acid, the higher  $[H_3O^+]$  is at equilibrium, and the larger the value of  $K_a$* :

**The Range of  $K_a$  Values** Acid-dissociation constants of weak acids range over many orders of magnitude. Some benchmark  $K_a$  values for typical weak acids in Table 18.2 give an idea of the fraction of HA molecules that dissociate into ions.

**Figure 18.2** Reaction of zinc with a strong acid (left) and a weak acid (right).

Source: © McGraw-Hill Education/Stephen Frisch, photographer

**Table 18.2**

**Magnitude of  $K_a$  Values and Percent Dissociation for Weak Acids**

Magnitude of $K_a$	% Dissociation in a 1 M Solution of HA	Specific Example ( $K_a$ Value, % Dissociation)
Relatively high $K_a$ ( $\sim 10^{-2}$ )	$\sim 10\%$	1 M chlorous acid ( $\text{HClO}_2$ ) ( $K_a = 1.1 \times 10^{-2}$ , 10.%)
Moderate $K_a$ ( $\sim 10^{-5}$ )	$\sim 0.3\%$	1 M acetic acid ( $\text{CH}_3\text{COOH}$ ) ( $K_a = 1.8 \times 10^{-5}$ , 0.42%)
Relatively low $K_a$ ( $\sim 10^{-10}$ )	$\sim 0.001\%$	1 M hydrocyanic acid (HCN) ( $K_a = 6.2 \times 10^{-10}$ , 0.0025%)

Thus, for solutions of the same initial HA concentration, *the smaller the  $K_a$ , the lower the percent dissociation of HA*:

Table 18.3

 $K_a$  Values for Some Monoprotic Acids at 25°C

Name (Formula)*	Lewis Structure*	Dissociation Reaction	$K_a$
Chlorous acid (HClO <sub>2</sub> )	$\text{H}-\ddot{\text{O}}-\ddot{\text{C}}=\ddot{\text{O}}$	$\text{HClO}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{ClO}_2^-(aq)$	$1.1 \times 10^{-2}$
Nitrous acid (HNO <sub>2</sub> )	$\text{H}-\ddot{\text{O}}-\ddot{\text{N}}=\ddot{\text{O}}$	$\text{HNO}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{NO}_2^-(aq)$	$7.1 \times 10^{-4}$
Hydrofluoric acid (HF)	$\text{H}-\ddot{\text{F}}:$	$\text{HF}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{F}^-(aq)$	$6.8 \times 10^{-4}$
Formic acid (HCOOH)	$\begin{array}{c} \text{:O:} \\ \parallel \\ \text{H}-\text{C}-\ddot{\text{O}}-\text{H} \end{array}$	$\text{HCOOH}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{HCOO}^-(aq)$	$1.8 \times 10^{-4}$
Acetic acid (CH <sub>3</sub> COOH)	$\begin{array}{c} \text{H} \quad \text{:O:} \\   \quad \parallel \\ \text{H}-\text{C}-\text{C}-\ddot{\text{O}}-\text{H} \\   \\ \text{H} \end{array}$	$\text{CH}_3\text{COOH}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{CH}_3\text{COO}^-(aq)$	$1.8 \times 10^{-5}$
Propanoic acid (CH <sub>3</sub> CH <sub>2</sub> COOH)	$\begin{array}{c} \text{H} \quad \text{H} \quad \text{:O:} \\   \quad   \quad \parallel \\ \text{H}-\text{C}-\text{C}-\text{C}-\ddot{\text{O}}-\text{H} \\   \quad   \\ \text{H} \quad \text{H} \end{array}$	$\text{CH}_3\text{CH}_2\text{COOH}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{CH}_3\text{CH}_2\text{COO}^-(aq)$	$1.3 \times 10^{-5}$
Hypochlorous acid (HClO)	$\text{H}-\ddot{\text{O}}-\ddot{\text{C}}:$	$\text{HClO}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{ClO}^-(aq)$	$2.9 \times 10^{-8}$
Hydrocyanic acid (HCN)	$\text{H}-\text{C} \equiv \text{N}:$	$\text{HCN}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{CN}^-(aq)$	$6.2 \times 10^{-10}$

ACID STRENGTH ↑

\*Red type indicates the ionizable proton; all atoms have zero formal charge.

Table 18.3 lists  $K_a$  values of some weak *monoprotic* acids, those with one ionizable proton. (A more extensive list is in Appendix C.) Note that the ionizable proton in organic acids is bound to the O in —COOH; H atoms bonded to C do *not* ionize.

## Classifying the Relative Strengths of Acids and Bases

Using a table of  $K_a$  values is the surest way to quantify strengths of weak acids, but you can classify acids and bases qualitatively as strong or weak from their formulas:

- **Strong acids.** Two types of strong acids, with examples *you should memorize*, are
  1. The hydrohalic acids HCl, HBr, and HI
  2. Oxoacids in which the number of O atoms exceeds the number of ionizable protons by two or more, such as HNO<sub>3</sub>, H<sub>2</sub>SO<sub>4</sub>, and HClO<sub>4</sub>; for example, in the case of H<sub>2</sub>SO<sub>4</sub>, 4 O's – 2 H's = 2
- **Weak acids.** There are many *more* weak acids than strong ones. Four types are
  1. The hydrohalic acid HF
  2. Acids in which H is not bonded to O or to a halogen, such as HCN and H<sub>2</sub>S
  3. Oxoacids in which the number of O atoms equals or exceeds by one the number of ionizable protons, such as HClO, HNO<sub>2</sub>, and H<sub>3</sub>PO<sub>4</sub>
  4. Carboxylic acids (general formula RCOOH, with the ionizable proton shown in red), such as CH<sub>3</sub>COOH and C<sub>6</sub>H<sub>5</sub>COOH
- **Strong bases.** Water-soluble compounds containing O<sup>2-</sup> or OH<sup>-</sup> ions are strong bases. The cations are usually those of the most active metals:
  1. M<sub>2</sub>O or MOH, where M = Group 1A(1) metal (Li, Na, K, Rb, Cs)
  2. MO or M(OH)<sub>2</sub>, where M = Group 2A(2) metal (Ca, Sr, Ba)  
[MgO<sub>2</sub> and Mg(OH)<sub>2</sub> are only slightly soluble in water, but the soluble portion dissociates completely.]
- **Weak bases.** Many compounds with an electron-rich nitrogen atom are weak bases (none is an Arrhenius base). The common structural feature is an N atom with a lone electron pair (shown in blue):
  1. Ammonia ( $\overset{\cdot\cdot}{\text{N}}\text{H}_3$ )
  2. Amines (general formula R $\overset{\cdot\cdot}{\text{N}}\text{H}_2$ , R<sub>2</sub> $\overset{\cdot\cdot}{\text{N}}\text{H}$ , or R<sub>3</sub> $\overset{\cdot\cdot}{\text{N}}$ ), such as CH<sub>3</sub>CH<sub>2</sub> $\overset{\cdot\cdot}{\text{N}}\text{H}_2$ , (CH<sub>3</sub>)<sub>2</sub> $\overset{\cdot\cdot}{\text{N}}\text{H}$ , and (C<sub>3</sub>H<sub>7</sub>)<sub>3</sub> $\overset{\cdot\cdot}{\text{N}}$

### Classifying Acid and Base Strength from the Chemical Formula

#### SAMPLE PROBLEM 18.1

**Problem** Classify each of the following compounds as a strong acid, weak acid, strong base, or weak base, and write the  $K_a$  expression for any weak acid:

(a) KOH    (b)  $(\text{CH}_3)_2\text{CHCOOH}$     (c)  $\text{H}_2\text{SeO}_4$     (d)  $(\text{CH}_3)_2\text{CHNH}_2$

**Plan** We examine the formula and classify each compound as acid or base, using the text descriptions. Particular points to note for acids are the numbers of O atoms relative to ionizable H atoms and the presence of the  $-\text{COOH}$  group. For bases, we note the nature of the cation or the presence of an N atom that has a lone pair.

**Solution** (a) **Strong base:** KOH is one of the Group 1A(1) hydroxides.

(b) **Weak acid:**  $(\text{CH}_3)_2\text{CHCOOH}$  is a carboxylic acid, as indicated by the  $-\text{COOH}$  group; the dissociation reaction is:

and

$$K_a = \frac{[\text{H}_3\text{O}^+][(\text{CH}_3)_2\text{CHCOO}^-]}{[(\text{CH}_3)_2\text{CHCOOH}]}$$

(c) **Strong acid:**  $\text{H}_2\text{SeO}_4$  is an oxoacid in which the number of O atoms exceeds the number of ionizable protons by 2.

(d) **Weak base:**  $(\text{CH}_3)_2\text{CHNH}_2$  has a lone electron pair on the N and is an amine.

#### FOLLOW-UP PROBLEMS

*Brief Solutions for all Follow-up Problems appear at the end of the chapter.*

**18.1A** Which member of each pair is the stronger acid or base?

(a) HClO or  $\text{HClO}_3$     (b) HCl or  $\text{CH}_3\text{COOH}$     (c) NaOH or  $\text{CH}_3\text{NH}_2$

**18.1B** Classify each of the following compounds as a strong acid, weak acid, strong base, or weak base, and write the  $K_a$  expression for any weak acid:

(a)  $(\text{CH}_3)_3\text{N}$     (b) HI    (c) HBrO    (d)  $\text{Ca}(\text{OH})_2$

**SOME SIMILAR PROBLEMS** 18.15–18.18

## Summary of Section 18.1

- › In aqueous solution, water binds the proton released from an acid to form a hydrated species represented by  $\text{H}_3\text{O}^+(aq)$ .
- › By the Arrhenius definition, acids contain H and yield  $\text{H}_3\text{O}^+$  in water, bases contain OH and yield  $\text{OH}^-$  in water, and an acid-base reaction (neutralization) is the reaction of  $\text{H}^+$  and  $\text{OH}^-$  to form  $\text{H}_2\text{O}$ .
- › Acid strength depends on  $[\text{H}_3\text{O}^+]$  relative to  $[\text{HA}]$  in aqueous solution. Strong acids dissociate completely and weak acids slightly.
- › The extent of dissociation is expressed by the acid-dissociation constant,  $K_a$ . Most weak acids have  $K_a$  values ranging from about  $10^{-2}$  to  $10^{-10}$ .
- › Many acids and bases can be classified as strong or weak based on their formulas.

## 18.2 AUTOIONIZATION OF WATER AND THE pH SCALE

Before we discuss the next major acid-base definition, let's examine a crucial property of water that enables us to quantify  $[\text{H}_3\text{O}^+]$ : *water dissociates very slightly into ions* in an equilibrium process known as **autoionization** (or *self-ionization*):

## The Equilibrium Nature of Autoionization: The Ion-Product Constant for Water ( $K_w$ )

Like any equilibrium process, the autoionization of water is described quantitatively by an equilibrium constant:

$$K_c = \frac{[\text{H}_3\text{O}^+][\text{OH}^-]}{[\text{H}_2\text{O}]^2}$$

Because the concentration of  $\text{H}_2\text{O}$  (55.5 M) remains essentially constant, it is considered a pure liquid and is eliminated from the equilibrium expression. Thus, we obtain the **ion-product constant for water,  $K_w$** :

$$K_c \times (1)^2 = K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14} \text{ (at } 25^\circ\text{C)} \quad (18.2)$$

Notice that *one  $\text{H}_3\text{O}^+$  ion and one  $\text{OH}^-$  ion form for each  $\text{H}_2\text{O}$  molecule that dissociates*. Therefore, in pure water, we find that

$$[\text{H}_3\text{O}^+] = [\text{OH}^-] = \sqrt{1.0 \times 10^{-14}} = 1.0 \times 10^{-7} \text{ M (at } 25^\circ\text{C)}$$

Since pure water has a concentration of about 55.5 M, these equilibrium concentrations are attained when only 1 in 555 million water molecules dissociates reversibly into ions!

Autoionization of water affects aqueous acid-base chemistry in two major ways:

1. A change in  $[\text{H}_3\text{O}^+]$  causes an inverse change in  $[\text{OH}^-]$ , and vice versa:

Recall from Le Châtelier's principle (Section 17.6) that a change in concentration shifts the equilibrium position but does *not* change the equilibrium constant. Therefore, if some acid is added,  $[\text{H}_3\text{O}^+]$  increases and  $[\text{OH}^-]$  decreases as the autoionization reaction proceeds to the left and the ions react to form water; similarly, if some base is added,  $[\text{OH}^-]$  increases and  $[\text{H}_3\text{O}^+]$  decreases. In both cases, as long as the temperature is constant, the value of  $K_w$  is constant.

2. Both ions are present in all aqueous systems. Thus, all acidic solutions contain a low  $[\text{OH}^-]$ , and all basic solutions contain a low  $[\text{H}_3\text{O}^+]$ . The equilibrium nature of autoionization allows us to define “acidic” and “basic” solutions in terms of relative magnitudes of  $[\text{H}_3\text{O}^+]$  and  $[\text{OH}^-]$ :

Figure 18.3 summarizes these relationships. Moreover, if you know the value of  $K_w$  at a particular temperature and the concentration of one of the two ions, you can find the concentration of the other:

$$[\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} \quad \text{or} \quad [\text{OH}^-] = \frac{K_w}{[\text{H}_3\text{O}^+]}$$

**Figure 18.3** The relationship between  $[\text{H}_3\text{O}^+]$  and  $[\text{OH}^-]$  and the relative acidity of solutions.

## SAMPLE PROBLEM 18.2

Calculating  $[H_3O^+]$  or  $[OH^-]$  in Aqueous Solution

**Problem** A research chemist adds a measured amount of HCl gas to pure water at 25°C and obtains a solution with  $[H_3O^+] = 3.0 \times 10^{-4} M$ . Calculate  $[OH^-]$ . Is the solution neutral, acidic, or basic?

**Plan** We use the known value of  $K_w$  at 25°C ( $1.0 \times 10^{-14}$ ) and the given  $[H_3O^+]$  ( $3.0 \times 10^{-4} M$ ) to solve for  $[OH^-]$ . Then we compare  $[H_3O^+]$  with  $[OH^-]$  to determine whether the solution is acidic, basic, or neutral (see Figure 18.3).

**Solution** Calculating  $[OH^-]$ :

$$[OH^-] = \frac{K_w}{[H_3O^+]} = \frac{1.0 \times 10^{-14}}{3.0 \times 10^{-4}} = 3.3 \times 10^{-11} M$$

Because  $[H_3O^+] > [OH^-]$ , the solution is **acidic**.

**Check** It makes sense that adding an acid to water results in an acidic solution. Also, since  $[H_3O^+]$  is greater than  $10^{-7} M$ ,  $[OH^-]$  must be less than  $10^{-7} M$  to give a constant  $K_w$ .

## FOLLOW-UP PROBLEMS

**18.2A** Calculate  $[H_3O^+]$  in a solution that has  $[OH^-] = 6.7 \times 10^{-2} M$  at 25°C. Is the solution neutral, acidic, or basic?

**18.2B** An aqueous solution of window cleaner has  $[H_3O^+] = 1.8 \times 10^{-10} M$  at 25°C. Calculate  $[OH^-]$ . Is the solution neutral, acidic, or basic?

**SOME SIMILAR PROBLEMS** 18.27–18.30

**Figure 18.4** The pH values of some familiar aqueous solutions.

## Expressing the Hydronium Ion Concentration: The pH Scale

In aqueous solutions,  $[H_3O^+]$  can vary from about  $10 M$  to  $10^{-15} M$ . To handle numbers with negative exponents more conveniently in calculations, we convert them to positive numbers using a numerical system called a *p-scale*, the negative of the common (base-10) logarithm of the number. Applying this numerical system to  $[H_3O^+]$  gives **pH**, the negative of the common logarithm of  $[H^+]$  (or  $[H_3O^+]$ ):

$$\text{pH} = -\log [H_3O^+] \quad (18.3)$$

What is the pH of a  $10^{-12} M H_3O^+$  solution?

$$\text{pH} = -\log [H_3O^+] = -\log 10^{-12} = (-1)(-12) = 12$$

Similarly, a  $10^{-3} M H_3O^+$  solution has a pH of 3, and a  $5.4 \times 10^{-4} M H_3O^+$  solution has a pH of 3.27:

$$\text{pH} = -\log [H_3O^+] = (-1)(\log 5.4 + \log 10^{-4}) = 3.27$$

As with any measurement, the number of significant figures in a pH value reflects the precision with which the concentration is known. However, a pH value is a logarithm, so the number of significant figures in the concentration equals the number of digits *to the right of the decimal point in the pH value* (see Appendix A). In the preceding example,  $5.4 \times 10^{-4} M$  has two significant figures, so its negative logarithm, 3.27, has two digits to the right of the decimal point.

Note in particular that *the higher the pH, the lower the  $[H_3O^+]$* . Therefore, *an acidic solution has a lower pH (higher  $[H_3O^+]$ ) than a basic solution*. At 25°C in pure water,  $[H_3O^+]$  is  $1.0 \times 10^{-7} M$ , so

$$\text{pH of an acidic solution} < 7.00$$

$$\text{pH of a neutral solution} = 7.00$$

$$\text{pH of a basic solution} > 7.00$$

Figure 18.4 shows that the pH values of some familiar aqueous solutions fall within a range of 0 to 14.

Table 18.4

The Relationship Between  $K_a$  and  $pK_a$ 

Acid Name (Formula)	$K_a$ at 25°C	$pK_a$
Hydrogen sulfate ion ( $\text{HSO}_4^-$ )	$1.0 \times 10^{-2}$	1.99
Nitrous acid ( $\text{HNO}_2$ )	$7.1 \times 10^{-4}$	3.15
Acetic acid ( $\text{CH}_3\text{COOH}$ )	$1.8 \times 10^{-5}$	4.75
Hypobromous acid ( $\text{HBrO}$ )	$2.3 \times 10^{-9}$	8.64
Phenol ( $\text{C}_6\text{H}_5\text{OH}$ )	$1.0 \times 10^{-10}$	10.00

Because the pH scale is logarithmic, a solution of pH 1.0 has an  $[\text{H}_3\text{O}^+]$  that is 10 times higher than that of a pH 2.0 solution, 100 times higher than that of a pH 3.0 solution, and so forth. To find the  $[\text{H}_3\text{O}^+]$  from the pH, you perform the opposite arithmetic process; that is, you find the negative antilog of pH:

$$[\text{H}_3\text{O}^+] = 10^{-\text{pH}}$$

A p-scale is used to express other quantities as well:

1. Hydroxide ion concentration can be expressed as pOH:

$$\text{pOH} = -\log [\text{OH}^-]$$

*Acidic solutions have a higher pOH (lower  $[\text{OH}^-]$ ) than basic solutions.*

2. Equilibrium constants can be expressed as pK:

$$\text{pK} = -\log K$$

Specifically for weak acids:

$$\text{p}K_a = -\log K_a \text{ and } K_a = 10^{-\text{p}K_a}$$

A low pK corresponds to a high K. So

- a reaction that reaches equilibrium with mostly products present (proceeds far to the right) has a low pK (high K);
- a reaction that has mostly reactants present at equilibrium has a high pK (low K).

Table 18.4 shows this relationship for aqueous equilibria of some weak acids.

**The Relationships Among pH, pOH, and  $pK_w$**  Taking the negative log of both sides of the  $K_w$  expression gives a useful relationship among  $pK_w$ , pH, and pOH:

$$\begin{aligned} K_w &= [\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14} \text{ (at } 25^\circ\text{C)} \\ -\log K_w &= (-\log [\text{H}_3\text{O}^+]) + (-\log [\text{OH}^-]) = -\log (1.0 \times 10^{-14}) \end{aligned}$$

$$\text{p}K_w = \text{pH} + \text{pOH} = 14.00 \quad (\text{at } 25^\circ\text{C}) \quad \mathbf{(18.4)}$$

Note these important points:

1. The sum of pH and pOH is  $pK_w$  for any aqueous solution at any temperature, and  $pK_w$  equals 14.00 at 25°C.
2. Because  $K_w$  is constant, pH, pOH,  $[\text{H}_3\text{O}^+]$ , and  $[\text{OH}^-]$  are interrelated:
  - $[\text{H}_3\text{O}^+]$  and  $[\text{OH}^-]$  change in opposite directions.
  - pH and pOH also change in opposite directions.
  - At 25°C, the product of  $[\text{H}_3\text{O}^+]$  and  $[\text{OH}^-]$  is  $1.0 \times 10^{-14}$ , and the sum of pH and pOH is 14.00 (Figure 18.5, next page).

**Calculating pH for Strong Acids and Bases** Since strong acids and bases dissociate completely, calculating pH,  $[\text{H}_3\text{O}^+]$ ,  $[\text{OH}^-]$ , and pOH for these substances is straightforward:

- The equilibrium concentration of  $\text{H}_3\text{O}^+$  is equal to the initial concentration of a strong acid: 0.200 M HCl dissociates to produce 0.200 M  $\text{H}_3\text{O}^+$ .
- The equilibrium concentration of  $\text{OH}^-$  is equal to the initial concentration of a Group 1A(1) hydroxide: 0.200 M KOH dissociates to produce 0.200 M  $\text{OH}^-$ .

**Figure 18.5** The relationships among  $[\text{H}_3\text{O}^+]$ , pH,  $[\text{OH}^-]$ , and pOH.

	$[\text{H}_3\text{O}^+]$	pH	$[\text{OH}^-]$	pOH
BASIC	$1.0 \times 10^{-15}$	15.00	$1.0 \times 10^1$	-1.00
	$1.0 \times 10^{-14}$	14.00	$1.0 \times 10^0$	0.00
	$1.0 \times 10^{-13}$	13.00	$1.0 \times 10^{-1}$	1.00
	$1.0 \times 10^{-12}$	12.00	$1.0 \times 10^{-2}$	2.00
	$1.0 \times 10^{-11}$	11.00	$1.0 \times 10^{-3}$	3.00
	$1.0 \times 10^{-10}$	10.00	$1.0 \times 10^{-4}$	4.00
	$1.0 \times 10^{-9}$	9.00	$1.0 \times 10^{-5}$	5.00
	$1.0 \times 10^{-8}$	8.00	$1.0 \times 10^{-6}$	6.00
NEUTRAL	$1.0 \times 10^{-7}$	7.00	$1.0 \times 10^{-7}$	7.00
ACIDIC	$1.0 \times 10^{-6}$	6.00	$1.0 \times 10^{-8}$	8.00
	$1.0 \times 10^{-5}$	5.00	$1.0 \times 10^{-9}$	9.00
	$1.0 \times 10^{-4}$	4.00	$1.0 \times 10^{-10}$	10.00
	$1.0 \times 10^{-3}$	3.00	$1.0 \times 10^{-11}$	11.00
	$1.0 \times 10^{-2}$	2.00	$1.0 \times 10^{-12}$	12.00
	$1.0 \times 10^{-1}$	1.00	$1.0 \times 10^{-13}$	13.00
	$1.0 \times 10^0$	0.00	$1.0 \times 10^{-14}$	14.00
	$1.0 \times 10^1$	-1.00	$1.0 \times 10^{-15}$	15.00

- The equilibrium concentration of  $\text{OH}^-$  is equal to twice the initial concentration of a Group 2A(2) hydroxide:  $0.200 \text{ M Ba(OH)}_2$  dissociates to produce  $2(0.200 \text{ M}) = 0.400 \text{ M OH}^-$  since there are two moles of  $\text{OH}^-$  in every mole of  $\text{Ba(OH)}_2$ .

**SAMPLE PROBLEM 18.3****Calculating  $[\text{H}_3\text{O}^+]$ , pH,  $[\text{OH}^-]$ , and pOH for Strong Acids and Bases**

**Problem** Calculate  $[\text{H}_3\text{O}^+]$ , pH,  $[\text{OH}^-]$ , and pOH for each solution at  $25^\circ\text{C}$ :

- (a)  $0.30 \text{ M HNO}_3$ , used for etching copper metal  
 (b)  $0.0042 \text{ M Ca(OH)}_2$ , used in leather tanning to remove hair from hides

**Plan** We know that  $\text{HNO}_3$  is a strong acid and dissociates completely; thus,  $[\text{H}_3\text{O}^+] = [\text{HNO}_3]_{\text{init}}$ . Similarly,  $\text{Ca(OH)}_2$  is a strong base and dissociates completely; the molar ratio is  $1 \text{ mol Ca(OH)}_2/2 \text{ mol OH}^-$  so  $[\text{OH}^-] = 2[\text{Ca(OH)}_2]_{\text{init}}$ . We use these concentrations and the value of  $K_w$  at  $25^\circ\text{C}$  ( $1.0 \times 10^{-14}$ ) to find  $[\text{OH}^-]$  or  $[\text{H}_3\text{O}^+]$ , which we then use to calculate pH and pOH.

**Solution** (a) For  $0.30 \text{ M HNO}_3$ :

$$\begin{aligned}
 [\text{H}_3\text{O}^+] &= 0.30 \text{ M} \\
 \text{pH} &= -\log [\text{H}_3\text{O}^+] = -\log 0.30 = 0.52 \\
 [\text{OH}^-] &= \frac{K_w}{[\text{H}_3\text{O}^+]} = \frac{1.0 \times 10^{-14}}{0.30} = 3.3 \times 10^{-14} \text{ M} \\
 \text{pOH} &= -\log [\text{OH}^-] = -\log (3.3 \times 10^{-14}) = 13.48
 \end{aligned}$$

(b) For  $0.0042 \text{ M Ca(OH)}_2$ :  $\text{Ca(OH)}_2(\text{aq}) \rightarrow \text{Ca}^{2+}(\text{aq}) + 2\text{OH}^-(\text{aq})$

$$\begin{aligned}
 [\text{OH}^-] &= 2(0.0042 \text{ M}) = 0.0084 \text{ M} \\
 \text{pOH} &= -\log [\text{OH}^-] = -\log (0.0084) = 2.08 \\
 [\text{H}_3\text{O}^+] &= \frac{K_w}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{0.0084} = 1.2 \times 10^{-12} \text{ M} \\
 \text{pH} &= -\log [\text{H}_3\text{O}^+] = -\log (1.2 \times 10^{-12}) = 11.92
 \end{aligned}$$

**Check** The strong acid has  $\text{pH} < 7$  and the strong base has a  $\text{pH} > 7$ , as expected. In each case,  $\text{pH} + \text{pOH} = 14$ , so the arithmetic seems correct.

## FOLLOW-UP PROBLEMS

**18.3A** Sodium hydroxide is used to clear clogged drains. A solution of NaOH has a pOH of 4.48 at 25°C. What are its pH,  $[\text{OH}^-]$ , and  $[\text{H}_3\text{O}^+]$ ?

**18.3B** Hydrochloric acid is sold commercially under the name *muriatic acid* and is used to clean concrete masonry. A dilute solution of HCl has a pH of 2.28 at 25°C. Calculate its pOH,  $[\text{H}_3\text{O}^+]$ , and  $[\text{OH}^-]$ .

**SOME SIMILAR PROBLEMS** 18.23–18.30

**Measuring pH** In the laboratory, pH values are usually obtained in two ways:

1. **Acid-base indicators** are organic molecules whose colors depend on the acidity of the solution in which they are dissolved. A pH can be estimated quickly with *pH paper*; a paper strip impregnated with one or a mixture of indicators. A drop of solution is placed on the strip, and the color is compared with a chart (Figure 18.6A).

2. A *pH meter* measures  $[\text{H}_3\text{O}^+]$  by means of two electrodes immersed in the test solution. One electrode supplies a reference system; the other consists of a very thin glass membrane that separates a known internal  $[\text{H}_3\text{O}^+]$  from the unknown external  $[\text{H}_3\text{O}^+]$ . The difference in  $[\text{H}_3\text{O}^+]$  creates a voltage difference across the membrane, which is displayed in pH units (Figure 18.6B). We examine this device in Chapter 21.

### Summary of Section 18.2

- ▶ Pure water has a low conductivity because it autoionizes to a small extent in a process whose equilibrium constant is the ion-product constant for water,  $K_w$  ( $1.0 \times 10^{-14}$  at 25°C).
- ▶  $[\text{H}_3\text{O}^+]$  and  $[\text{OH}^-]$  are inversely related: in acidic solution,  $[\text{H}_3\text{O}^+]$  is greater than  $[\text{OH}^-]$ ; the reverse is true in basic solution; and the two are equal in neutral solution.
- ▶ To express small values of  $[\text{H}_3\text{O}^+]$ , we use the pH scale:  $\text{pH} = -\log [\text{H}_3\text{O}^+]$ . Similarly,  $\text{pOH} = -\log [\text{OH}^-]$ , and  $\text{p}K = -\log K$ .
- ▶ A high pH corresponds to a low  $[\text{H}_3\text{O}^+]$ . In acidic solutions,  $\text{pH} < 7.00$ ; in basic solutions,  $\text{pH} > 7.00$ ; and in neutral solutions,  $\text{pH} = 7.00$ . The sum of pH and pOH equals  $\text{p}K_w$  (14.00 at 25°C).
- ▶ A pH is typically measured with either an acid-base indicator or a pH meter.

## 18.3

## PROTON TRANSFER AND THE BRØNSTED-LOWRY ACID-BASE DEFINITION

Earlier we noted a key limitation of the Arrhenius definition: many substances that yield  $\text{OH}^-$  ions in water do not contain OH in their formulas. Examples include ammonia, the amines, and many salts of weak acids, such as NaF. Another limitation is that water had to be the solvent for acid-base reactions. In the early 20<sup>th</sup> century, J. N. Brønsted and T. M. Lowry suggested definitions that remove these limitations. (We introduced some of these ideas in Section 4.4.)

According to the **Brønsted-Lowry acid-base definition**,

- An *acid* is a **proton donor**, any species that donates an  $\text{H}^+$  ion. An acid must contain H in its formula;  $\text{HNO}_3$  and  $\text{H}_2\text{PO}_4^-$  are two of many examples. All Arrhenius acids are Brønsted-Lowry acids.
- A *base* is a **proton acceptor**, any species that accepts an  $\text{H}^+$  ion. A base must contain a lone pair of electrons to bind  $\text{H}^+$ ; a few examples are  $\text{NH}_3$ ,  $\text{CO}_3^{2-}$ , and  $\text{F}^-$ , as well as  $\text{OH}^-$  itself. Brønsted-Lowry bases are not Arrhenius bases, but all Arrhenius bases contain the Brønsted-Lowry base  $\text{OH}^-$ .

From this perspective, an acid-base reaction occurs when *one species donates a proton and another species simultaneously accepts it: an acid-base reaction is thus a proton-transfer process*. Acid-base reactions can occur between gases, in nonaqueous solutions, and in heterogeneous mixtures, as well as in aqueous solutions.

**Figure 18.7** Dissolving of an acid or base in water as a Brønsted-Lowry acid-base reaction. **A**, The acid HCl dissolving in the base water. **B**, The base NH<sub>3</sub> dissolving in the acid water.

According to this definition, an acid-base reaction occurs even when an acid (or a base) just dissolves in water, because water acts as the proton acceptor (or donor):

1. *Acid donates a proton to water* (Figure 18.7A). When HCl dissolves in water, an H<sup>+</sup> ion (a proton) is transferred from HCl to H<sub>2</sub>O, where it becomes attached to a lone pair of electrons on the O atom, forming H<sub>3</sub>O<sup>+</sup>. Thus, HCl (the acid) has *donated* the H<sup>+</sup>, and H<sub>2</sub>O (the base) has *accepted* it:

2. *Base accepts a proton from water* (Figure 18.7B). When ammonia dissolves in water, an H<sup>+</sup> from H<sub>2</sub>O is transferred to the lone pair of N, forming NH<sub>4</sub><sup>+</sup>, and the H<sub>2</sub>O becomes an OH<sup>-</sup> ion:

In this case, H<sub>2</sub>O (the acid) has *donated* the H<sup>+</sup>, and NH<sub>3</sub> (the base) has *accepted* it.

Note that H<sub>2</sub>O is *amphiprotic*: it acts as a base (accepts an H<sup>+</sup>) in one case and as an acid (donates an H<sup>+</sup>) in the other. Many other species are amphiprotic as well.

## Conjugate Acid-Base Pairs

The Brønsted-Lowry definition provides a new way to look at acid-base reactions because it focuses on the reactants *and* the products as acids and bases. For example, let's examine the reaction between hydrogen sulfide and ammonia:

In the forward reaction, H<sub>2</sub>S acts as an acid by donating an H<sup>+</sup> to NH<sub>3</sub>, which acts as a base by accepting it. In the reverse reaction, the ammonium ion, NH<sub>4</sub><sup>+</sup>, acts as an acid by donating an H<sup>+</sup> to the hydrogen sulfide ion, HS<sup>-</sup>, which acts as a base. Notice that the acid, H<sub>2</sub>S, becomes a base, HS<sup>-</sup>, and the base, NH<sub>3</sub>, becomes an acid, NH<sub>4</sub><sup>+</sup>.

In Brønsted-Lowry terminology, H<sub>2</sub>S and HS<sup>-</sup> are a **conjugate acid-base pair**: HS<sup>-</sup> is the conjugate base of the acid H<sub>2</sub>S. Similarly, NH<sub>3</sub> and NH<sub>4</sub><sup>+</sup> are a conjugate acid-base pair: NH<sub>4</sub><sup>+</sup> is the conjugate acid of the base NH<sub>3</sub>. *Every acid has a conjugate base, and every base has a conjugate acid.* For any conjugate acid-base pair,

- The conjugate base has one *fewer* H and one *more* negative charge than the acid.
- The conjugate acid has one *more* H and one *fewer* negative charge than the base.

A Brønsted-Lowry acid-base reaction occurs when *an acid and a base react to form their conjugate base and conjugate acid, respectively*:

Table 18.5 shows some Brønsted-Lowry acid-base reactions. Note these points:

- Each reaction has an acid and a base as reactants *and* as products, comprising two conjugate acid-base pairs.
- Acids and bases can be neutral molecules, cations, or anions.
- The same species can be an acid or a base (amphiprotic), depending on the other species reacting. Water behaves this way in reactions 1 and 4 in Table 18.5 and HPO<sub>4</sub><sup>2-</sup> does so in reactions 4 and 6.

Table 18.5

The Conjugate Pairs in Some Acid-Base Reactions

	Acid	+	Base	$\rightleftharpoons$	Base	+	Acid
			Conjugate Pair				
					Conjugate Pair		
Reaction 1	HF	+	H <sub>2</sub> O	$\rightleftharpoons$	F <sup>-</sup>	+	H <sub>3</sub> O <sup>+</sup>
Reaction 2	HCOOH	+	CN <sup>-</sup>	$\rightleftharpoons$	HCOO <sup>-</sup>	+	HCN
Reaction 3	NH <sub>4</sub> <sup>+</sup>	+	CO <sub>3</sub> <sup>2-</sup>	$\rightleftharpoons$	NH <sub>3</sub>	+	HCO <sub>3</sub> <sup>-</sup>
Reaction 4	H <sub>2</sub> PO <sub>4</sub> <sup>-</sup>	+	OH <sup>-</sup>	$\rightleftharpoons$	HPO <sub>4</sub> <sup>2-</sup>	+	H <sub>2</sub> O
Reaction 5	H <sub>2</sub> SO <sub>4</sub>	+	N <sub>2</sub> H <sub>5</sub> <sup>+</sup>	$\rightleftharpoons$	HSO <sub>4</sub> <sup>-</sup>	+	N <sub>2</sub> H <sub>6</sub> <sup>2+</sup>
Reaction 6	HPO <sub>4</sub> <sup>2-</sup>	+	SO <sub>3</sub> <sup>2-</sup>	$\rightleftharpoons$	PO <sub>4</sub> <sup>3-</sup>	+	HSO <sub>3</sub> <sup>-</sup>

## SAMPLE PROBLEM 18.4

## Identifying Conjugate Acid-Base Pairs

**Problem** The following reactions are important environmental processes. Identify the conjugate acid-base pairs.

**Plan** To find the conjugate pairs, we find the species that donated an H<sup>+</sup> (acid) and the species that accepted it (base). The acid (or base) on the left becomes its conjugate base (or conjugate acid) on the right. Remember, the conjugate acid has one more H and one fewer negative charge than its conjugate base.

**Solution** (a) H<sub>2</sub>PO<sub>4</sub><sup>-</sup> has one more H<sup>+</sup> than HPO<sub>4</sub><sup>2-</sup>; CO<sub>3</sub><sup>2-</sup> has one fewer H<sup>+</sup> than HCO<sub>3</sub><sup>-</sup>. Therefore, H<sub>2</sub>PO<sub>4</sub><sup>-</sup> and HCO<sub>3</sub><sup>-</sup> are the acids, and HPO<sub>4</sub><sup>2-</sup> and CO<sub>3</sub><sup>2-</sup> are the bases. The conjugate acid-base pairs are H<sub>2</sub>PO<sub>4</sub><sup>-</sup>/HPO<sub>4</sub><sup>2-</sup> and HCO<sub>3</sub><sup>-</sup>/CO<sub>3</sub><sup>2-</sup>.

(b) H<sub>2</sub>O has one more H<sup>+</sup> than OH<sup>-</sup>; SO<sub>3</sub><sup>2-</sup> has one fewer H<sup>+</sup> than HSO<sub>3</sub><sup>-</sup>. The acids are H<sub>2</sub>O and HSO<sub>3</sub><sup>-</sup>; the bases are OH<sup>-</sup> and SO<sub>3</sub><sup>2-</sup>. The conjugate acid-base pairs are H<sub>2</sub>O/OH<sup>-</sup> and HSO<sub>3</sub><sup>-</sup>/SO<sub>3</sub><sup>2-</sup>.

## FOLLOW-UP PROBLEMS

**18.4A** Identify the conjugate acid-base pairs:

**18.4B** Give the formula of each of the following:

**SOME SIMILAR PROBLEMS** 18.43–18.52

## Student Hot Spot

Student data indicate that you may struggle with the identification of conjugate acid-base pairs. Access the Smartbook to view additional Learning Resources on this topic.

## Relative Acid-Base Strength and the Net Direction of Reaction

The *net* direction of an acid-base reaction depends on relative acid and base strengths: *A reaction proceeds to the greater extent in the direction in which a stronger acid and stronger base form a weaker acid and weaker base.*

**Competition for the Proton** The net direction of the reaction of H<sub>2</sub>S and NH<sub>3</sub> is to the right ( $K_c > 1$ ) because H<sub>2</sub>S is a stronger acid than NH<sub>4</sub><sup>+</sup>, the other acid present, and NH<sub>3</sub> is a stronger base than HS<sup>-</sup>, the other base:

You might think of the process as *a competition for the proton between the two bases*, NH<sub>3</sub> and HS<sup>-</sup>, in which NH<sub>3</sub> wins.

In effect, the extent of acid (HA) dissociation in water can be viewed as the result of a competition for the proton between the two bases,  $A^-$  and  $H_2O$ . Strong and weak acids give different results:

1. *Strong acids.* When the strong acid  $HNO_3$  dissolves, it completely transfers an  $H^+$  to the base,  $H_2O$ , forming the conjugate base  $NO_3^-$  and the conjugate acid  $H_3O^+$ :

Even though we show an equilibrium arrow here, the net direction is so far to the right that  $K_c \gg 1$  and the reaction is essentially complete.  $HNO_3$  is a stronger acid than  $H_3O^+$ , and  $H_2O$  is a stronger base than  $NO_3^-$ . Thus, with a strong HA,  $H_2O$  wins the competition for the proton because  $A^-$  is a *much* weaker base. In fact, *the only acidic species that remains in strong-acid solutions is  $H_3O^+$ .*

2. *Weak acids.* On the other hand, with weak acids such as HF, the  $A^-$  ( $F^-$  for this example) wins the competition because it is a stronger base than  $H_2O$  and the net direction is to the left ( $K_c < 1$ ), with the net result that only a small percentage of HF molecules dissociate:

**Ranking Conjugate Pairs** Based on evidence from many such reactions, we can rank conjugate pairs in terms of the ability of the acid to transfer its proton (Figure 18.8). Note that *a weaker acid has a stronger conjugate base*: the acid can't give up its proton very readily because its conjugate base attracts the proton too strongly.

**Figure 18.8** Strengths of conjugate acid-base pairs. The stronger the acid is, the weaker its conjugate base. The strongest acid is at top left and the strongest base at bottom right. When an acid reacts with a base farther down the list, the reaction proceeds to the right ( $K_c > 1$ ).

		ACID	BASE		
Strong	}	HCl	$Cl^-$	Negligible	}
		$H_2SO_4$	$HSO_4^-$		
		$HNO_3$	$NO_3^-$		
		$H_3O^+$	$H_2O$		
		$HSO_4^-$	$SO_4^{2-}$		
Weak	}	$H_2SO_3$	$HSO_3^-$	Weak	}
		$H_3PO_4$	$H_2PO_4^-$		
		HF	$F^-$		
		$CH_3COOH$	$CH_3COO^-$		
		$H_2CO_3$	$HCO_3^-$		
		$H_2S$	$HS^-$		
		$HSO_3^-$	$SO_3^{2-}$		
		$H_2PO_4^-$	$HPO_4^{2-}$		
		HCN	$CN^-$		
		$NH_4^+$	$NH_3$		
Negligible	}	$HCO_3^-$	$CO_3^{2-}$	Strong	}
		$HPO_4^{2-}$	$PO_4^{3-}$		
		$H_2O$	$OH^-$		
		$HS^-$	$S^{2-}$		
		$OH^-$	$O^{2-}$		

We use Figure 18.8 to predict the net direction of a reaction between any two pairs, that is, whether the equilibrium position lies to the right ( $K_c > 1$ , mostly products) or to the left ( $K_c < 1$ , mostly reactants). *A reaction proceeds to the right if an acid reacts with a base lower on the list.* The following two sample problems demonstrate this key idea.

## SAMPLE PROBLEM 18.5

## Predicting the Net Direction of an Acid-Base Reaction

**Problem** Predict the net direction and indicate whether  $K_c$  is greater or less than 1 for each of the following reactions (assume equal initial concentrations of all species):

**Plan** We identify the conjugate acid-base pairs and consult Figure 18.8 to see which acid and base are stronger. The reaction proceeds in the direction in which the stronger acid and base form the weaker acid and base. If the reaction *as written* proceeds to the right, then [products] is higher than [reactants], so  $K_c > 1$ .

**Solution** (a) The conjugate pairs are  $\text{H}_2\text{PO}_4^-/\text{HPO}_4^{2-}$  and  $\text{NH}_4^+/\text{NH}_3$ . Since  $\text{H}_2\text{PO}_4^-$  is higher on the list of acids, it is stronger than  $\text{NH}_4^+$ ; since  $\text{NH}_3$  is lower on the list of bases, it is stronger than  $\text{HPO}_4^{2-}$ . Therefore,

The net direction is to the right, so  $K_c > 1$ .

(b) The conjugate pairs are  $\text{H}_2\text{O}/\text{OH}^-$  and  $\text{H}_2\text{S}/\text{HS}^-$ . Since  $\text{H}_2\text{S}$  is higher on the list of acids, and  $\text{OH}^-$  is lower on the list of bases, we have

The net direction is to the left, so  $K_c < 1$ .

## FOLLOW-UP PROBLEMS

**18.5A** Use the following conjugate acid-base pairs and Figure 18.8 to write acid-base reactions with  $K_c$  values as specified:

**18.5B** Use balanced equations that show the net direction of the reaction to explain each of the following observations:

(a) You smell ammonia when  $\text{NH}_3$  dissolves in water.

(b) The odor goes away when you add an excess of  $\text{HCl}$  to the solution in part (a).

(c) The odor returns when you add an excess of  $\text{NaOH}$  to the solution in part (b).

**SOME SIMILAR PROBLEMS** 18.53–18.58

## SAMPLE PROBLEM 18.6

## Using Molecular Scenes to Predict the Net Direction of an Acid-Base Reaction

**Problem** Given that 0.10 M HX (blue and green) has a pH of 2.88, and 0.10 M HY (blue and orange) has a pH of 3.52, which scene best represents the final mixture after equimolar solutions of HX and  $\text{Y}^-$  are mixed?

**Plan** A stronger acid and base yield a weaker acid and base, so we have to determine the relative acid strengths of HX and HY in order to choose the correct molecular scene. The concentrations of the acid solutions are equal, so we can pick the stronger acid directly from the pH values of the two acid solutions. Because the stronger acid reacts to a greater extent, fewer molecules of it will be in the scene than molecules of the weaker acid.

**Solution** The HX solution has a lower pH (2.88) than the HY solution (3.52), so we know right away that HX is the stronger acid and  $X^-$  is the weaker base and that HY is the weaker acid and  $Y^-$  is the stronger base. Therefore, the reaction of HX and  $Y^-$  has  $K_c > 1$ , which means the equilibrium mixture will have more HY than HX. Scene 1 has equal numbers of HX and HY, which would occur if the acids were of equal strength, and scene 2 shows fewer HY than HX, which would occur if HY were stronger. Therefore, only scene 3 is consistent with the relative acid strengths.

#### FOLLOW-UP PROBLEMS

**18.6A** The left-hand scene in the margin represents the equilibrium mixture after 0.10 M solutions of HA (blue and red) and  $B^-$  (black) react: Does this reaction have a  $K_c$  greater or less than 1? Which acid is stronger, HA or HB?

**18.6B** The right-hand scene depicts an aqueous solution of two conjugate acid-base pairs: HC/ $C^-$  and HD/ $D^-$ . HD is a stronger acid than HC. What colors represent the base  $C^-$  and the base  $D^-$ ? Does the reaction between HC and  $D^-$  have a  $K_c$  greater or less than 1?

**A SIMILAR PROBLEM** 18.39

18.6A

18.6B

### › Summary of Section 18.3

- › The Brønsted-Lowry acid-base definition does not require that bases contain OH in their formula or that acid-base reactions occur in aqueous solution.
- › An acid is a species that donates a proton and a base is one that accepts it, so an acid-base reaction is a proton-transfer process.
- › When an acid donates a proton, it becomes the conjugate base; when a base accepts a proton, it becomes the conjugate acid. In an acid-base reaction, acids and bases form their conjugates. A stronger acid has a weaker conjugate base, and vice versa.
- › An acid-base reaction proceeds to the greater extent ( $K > 1$ ) in the direction in which a stronger acid and base form a weaker base and acid.

## 18.4 SOLVING PROBLEMS INVOLVING WEAK-ACID EQUILIBRIA

Just as you saw in Chapter 17 for equilibrium problems in general, there are two types of equilibrium problems involving weak acids and their conjugate bases:

1. Given equilibrium concentrations, find  $K_a$ .
2. Given  $K_a$  and some concentrations, find other equilibrium concentrations.

For all of these problems, we'll apply the same problem-solving approach, notation system, and assumptions:

- *The problem-solving approach.* Start with what is given in the problem and move toward what you want to find. Make a habit of applying the following steps:
  1. Write the balanced equation and  $K_a$  expression; these tell you what to find.
  2. Define  $x$  as the unknown change in concentration that occurs during the reaction. Frequently,  $x = [HA]_{\text{dissoc}}$ , the concentration of HA that dissociates, which, based on certain assumptions, also equals  $[H_3O^+]$  and  $[A^-]$  at equilibrium.
  3. Construct a reaction table (for most problems) that incorporates  $x$ .
  4. Make assumptions (usually that  $x$  is very small relative to the initial concentration) that simplify the calculations.
  5. Substitute the values into the  $K_a$  expression, and solve for  $x$ .
  6. Check that the assumptions are justified with the 5% test first used in Sample Problem 17.9. If they are not justified, use the quadratic formula to find  $x$ .

- *The notation system.* As always, molar concentration is indicated with brackets. A subscript indicates where the species comes from or when it occurs in the reaction process. For example,  $[\text{H}_3\text{O}^+]_{\text{from HA}}$  is the molar concentration of  $\text{H}_3\text{O}^+$  that comes from the dissociation of HA;  $[\text{HA}]_{\text{init}}$  is the initial molar concentration of HA, that is, before dissociation;  $[\text{HA}]_{\text{dissoc}}$  is the molar concentration of HA that dissociates; and so forth. A bracketed formula with *no* subscript represents the molar concentration of the species *at equilibrium*.
- *The assumptions.* We make two assumptions to simplify the arithmetic:
  1.  $[\text{H}_3\text{O}^+]$  from the autoionization of water is negligible. It is so much smaller than the  $[\text{H}_3\text{O}^+]$  from the dissociation of HA that we can neglect it in these problems:

$$[\text{H}_3\text{O}^+] = [\text{H}_3\text{O}^+]_{\text{from HA}} + [\text{H}_3\text{O}^+]_{\text{from H}_2\text{O}} \approx [\text{H}_3\text{O}^+]_{\text{from HA}}$$

Note that each molecule of HA that dissociates forms one  $\text{H}_3\text{O}^+$  and one  $\text{A}^-$ :

$$[\text{HA}]_{\text{dissoc}} = [\text{H}_3\text{O}^+] = [\text{A}^-]$$

2. A weak acid has a small  $K_a$ . Therefore, it dissociates to such a small extent that we can neglect the change in its concentration to find its equilibrium concentration:

$$[\text{HA}] = [\text{HA}]_{\text{init}} - [\text{HA}]_{\text{dissoc}} \approx [\text{HA}]_{\text{init}}$$

## Finding $K_a$ Given Concentrations

This type of problem involves finding  $K_a$  of a weak acid from the concentration of one of the species in solution, usually  $[\text{H}_3\text{O}^+]$  from a given pH:

You prepare an aqueous solution of HA and measure its pH. Thus, you know  $[\text{HA}]_{\text{init}}$ , can calculate  $[\text{H}_3\text{O}^+]$  from the pH, and then determine  $[\text{A}^-]$  and  $[\text{HA}]$  at equilibrium. You substitute these values into the  $K_a$  expression and solve for  $K_a$ . Let's go through the approach in a sample problem.

### SAMPLE PROBLEM 18.7

### Finding $K_a$ of a Weak Acid from the Solution pH

**Problem** Phenylacetic acid ( $\text{C}_6\text{H}_5\text{CH}_2\text{COOH}$ , simplified here to HPac; *see model*) builds up in the blood of persons with phenylketonuria, an inherited disorder that, if untreated, causes mental retardation and death. A study of the acid shows that the pH of 0.12 M HPac is 2.62. What is the  $K_a$  of phenylacetic acid?

**Plan** We are given  $[\text{HPac}]_{\text{init}}$  (0.12 M) and the pH (2.62) and must find  $K_a$ . As always, we first write the equation for HPac dissociation and the expression for  $K_a$  to see which values we need. We set up a reaction table and use the given pH to find  $[\text{H}_3\text{O}^+]$ , which equals  $[\text{Pac}^-]$  and  $[\text{HPac}]_{\text{dissoc}}$  (we assume that  $[\text{H}_3\text{O}^+]_{\text{from H}_2\text{O}}$  is negligible). To find  $[\text{HPac}]$ , we assume that, because it is a weak acid, very little dissociates, so  $[\text{HPac}]_{\text{init}} - [\text{HPac}]_{\text{dissoc}} = [\text{HPac}] \approx [\text{HPac}]_{\text{init}}$ . We make these assumptions, substitute the equilibrium values, solve for  $K_a$ , and then check the assumptions using the 5% rule (Sample Problem 17.9).

**Solution** Writing the dissociation equation and  $K_a$  expression:

Setting up a reaction table, with  $x = [\text{HPac}]_{\text{dissoc}} = [\text{H}_3\text{O}^+]_{\text{from HPac}} = [\text{Pac}^-]$ :

Concentration (M)	HPac(aq)	+	H <sub>2</sub> O(l)	⇌	H <sub>3</sub> O <sup>+</sup> (aq)	+	Pac <sup>-</sup> (aq)
Initial	0.12		—		0		0
Change	−x		—		+x		+x
Equilibrium	0.12 − x		—		x		x

Phenylalanine, one of the amino acids that make up aspartame, is metabolized to phenylacetic acid (model).

Calculating  $[\text{H}_3\text{O}^+]$ :

$$[\text{H}_3\text{O}^+] = 10^{-\text{pH}} = 10^{-2.62} = 2.4 \times 10^{-3} \text{ M}$$

Making the assumptions:

1. The calculated  $[\text{H}_3\text{O}^+]$  ( $2.4 \times 10^{-3} \text{ M}$ )  $\gg$   $[\text{H}_3\text{O}^+]_{\text{from H}_2\text{O}}$  ( $1.0 \times 10^{-7} \text{ M}$ ), so we assume that  $[\text{H}_3\text{O}^+] \approx [\text{H}_3\text{O}^+]_{\text{from HPac}} = [\text{Pac}^-] = x$  (the change in  $[\text{HPac}]$ , or  $[\text{HPac}]_{\text{dissoc}}$ ).
2. HPac is a weak acid, so we assume that  $[\text{HPac}] = 0.12 \text{ M} - x \approx 0.12 \text{ M}$ .

Solving for the equilibrium concentrations:

$$\begin{aligned} x \approx [\text{H}_3\text{O}^+] &= [\text{Pac}^-] = 2.4 \times 10^{-3} \text{ M} \\ [\text{HPac}] &= 0.12 \text{ M} - x = 0.12 \text{ M} - (2.4 \times 10^{-3} \text{ M}) \approx 0.12 \text{ M} \text{ (to 2 sf)} \end{aligned}$$

Substituting these values into  $K_a$ :

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{Pac}^-]}{[\text{HPac}]} \approx \frac{(2.4 \times 10^{-3})(2.4 \times 10^{-3})}{0.12} = 4.8 \times 10^{-5}$$

Checking the assumptions by finding the percent error in concentration:

1. For  $[\text{H}_3\text{O}^+]_{\text{from H}_2\text{O}}$ :  $\frac{1 \times 10^{-7} \text{ M}}{2.4 \times 10^{-3} \text{ M}} \times 100 = 4 \times 10^{-3}\%$  ( $< 5\%$ ; assumption is justified.)
2. For  $[\text{HPac}]_{\text{dissoc}}$ :  $\frac{2.4 \times 10^{-3} \text{ M}}{0.12 \text{ M}} \times 100 = 2.0\%$  ( $< 5\%$ ; assumption is justified.)

**Check** The  $[\text{H}_3\text{O}^+]$  makes sense: pH 2.62 should give  $[\text{H}_3\text{O}^+]$  between  $10^{-2}$  and  $10^{-3} \text{ M}$ . The  $K_a$  calculation also seems in the correct range:  $(10^{-3})^2/10^{-1} = 10^{-5}$ , and this value seems reasonable for a weak acid.

#### FOLLOW-UP PROBLEMS

**18.7A** The conjugate acid of ammonia is the weak acid  $\text{NH}_4^+$ . If a  $0.2 \text{ M}$   $\text{NH}_4\text{Cl}$  solution has a pH of 5.0, what is the  $K_a$  of  $\text{NH}_4^+$ ?

**18.7B** Over a million tons of acrylic acid ( $\text{H}_2\text{C}=\text{CHCOOH}$ ) are produced each year for manufacturing plastics, adhesives, and paint. A  $0.30 \text{ M}$  solution of the acid has a pH of 2.43. What is  $K_a$  for this acid?

**SOME SIMILAR PROBLEMS** 18.64, 18.65, 18.72, and 18.73

## Finding Concentrations Given $K_a$

The second type of equilibrium problem gives some concentration data and  $K_a$  and asks for the equilibrium concentration of some component. Such problems are very similar to those we solved in Chapter 17 in which a substance with a given initial concentration reacted to an unknown extent (see Sample Problems 17.8 to 17.10). We will use a reaction table in these problems to find the values, and, as we just found,  $[\text{H}_3\text{O}^+]_{\text{from H}_2\text{O}}$  is so small relative to  $[\text{H}_3\text{O}^+]_{\text{from HA}}$  that we will neglect it and enter the initial  $[\text{H}_3\text{O}^+]$  in all reaction tables as zero.

### SAMPLE PROBLEM 18.8

#### Determining Concentration and pH from $K_a$ and Initial $[\text{HA}]$

**Problem** Propanoic acid ( $\text{CH}_3\text{CH}_2\text{COOH}$ , which we simplify to HPr) is a carboxylic acid whose salts are used to retard mold growth in foods. What are the  $[\text{H}_3\text{O}^+]$  and the pH of  $0.10 \text{ M}$  HPr ( $K_a = 1.3 \times 10^{-5}$ )?

**Plan** We know the initial concentration ( $0.10 \text{ M}$ ) and  $K_a$  ( $1.3 \times 10^{-5}$ ) of HPr, and we need to find  $[\text{H}_3\text{O}^+]$  and pH. First, we write the balanced equation and the expression for  $K_a$ . We know  $[\text{HPr}]_{\text{init}}$  but not  $[\text{HPr}]$  (that is, the concentration at equilibrium). If we let  $x = [\text{HPr}]_{\text{dissoc}}$ ,  $x$  is also  $[\text{H}_3\text{O}^+]_{\text{from HPr}}$  and  $[\text{Pr}^-]$  because each HPr dissociates into one  $\text{H}_3\text{O}^+$  and one  $\text{Pr}^-$ . With this information, we set up a reaction table. We assume

that, because HPr has a small  $K_a$ , it dissociates very little. After solving for  $x$ , which is  $[\text{H}_3\text{O}^+]$ , we check the assumption. Then we use the value for  $[\text{H}_3\text{O}^+]$  to find the pH.

**Solution** Writing the balanced equation and expression for  $K_a$ :

Setting up a reaction table, with  $x = [\text{HPr}]_{\text{dissoc}} = [\text{H}_3\text{O}^+]_{\text{from HPr}} = [\text{Pr}^-] = [\text{H}_3\text{O}^+]$ :

Concentration (M)	HPr(aq)	+ H <sub>2</sub> O(l)	⇌	H <sub>3</sub> O <sup>+</sup> (aq)	+ Pr <sup>-</sup> (aq)
Initial	0.10	—		0	0
Change	-x	—		+x	+x
Equilibrium	0.10 - x	—		x	x

Making the assumption:  $K_a$  is small, so  $x$  is small compared with  $[\text{HPr}]_{\text{init}}$ ; therefore,  $[\text{HPr}]_{\text{init}} - x = [\text{HPr}] \approx [\text{HPr}]_{\text{init}}$ , or  $0.10 \text{ M} - x \approx 0.10 \text{ M}$ . Substituting into the  $K_a$  expression and solving for  $x$ :

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{Pr}^-]}{[\text{HPr}]} = 1.3 \times 10^{-5} \approx \frac{(x)(x)}{0.10}$$

$$x \approx \sqrt{(0.10)(1.3 \times 10^{-5})} = 1.1 \times 10^{-3} \text{ M} = [\text{H}_3\text{O}^+]$$

Checking the assumption for  $[\text{HPr}]_{\text{dissoc}}$ :

$$\frac{[\text{H}_3\text{O}^+]}{[\text{HPr}]_{\text{init}}} \times 100 = \frac{1.1 \times 10^{-3} \text{ M}}{0.10 \text{ M}} \times 100 = 1.1\% (<5\%; \text{assumption is justified.})$$

Finding the pH:

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log (1.1 \times 10^{-3}) = 2.96$$

**Check** The  $[\text{H}_3\text{O}^+]$  and pH seem reasonable for a dilute solution of a weak acid with a moderate  $K_a$ . By reversing the calculation, we can check the math:  $(1.1 \times 10^{-3})^2 / 0.10 = 1.2 \times 10^{-5}$ , which is within rounding of the given  $K_a$ .

**Comment** In Chapter 17 we introduced a benchmark, aside from the 5% rule, to see if the assumption is justified (see the discussion following Sample Problem 17.9):

- If  $\frac{[\text{HA}]_{\text{init}}}{K_a} > 400$ , the assumption is justified; neglecting  $x$  introduces an error  $<5\%$ .
- If  $\frac{[\text{HA}]_{\text{init}}}{K_a} < 400$ , the assumption is *not* justified; neglecting  $x$  introduces an error  $>5\%$ , so we solve a quadratic equation to find  $x$ .

In this sample problem, we have  $\frac{0.10}{1.3 \times 10^{-5}} = 7.7 \times 10^3$ , which is greater than 400. The alternative situation occurs in the next follow-up problem.

### FOLLOW-UP PROBLEMS

**18.8A** Cyanic acid (HOCN) is an extremely acrid, unstable substance. What are the  $[\text{H}_3\text{O}^+]$  and the pH of  $0.10 \text{ M}$  HOCN ( $K_a = 3.5 \times 10^{-4}$ )?

**18.8B** Benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ) is used as a food preservative. What are the  $[\text{H}_3\text{O}^+]$  and the pH of  $0.25 \text{ M}$   $\text{C}_6\text{H}_5\text{COOH}$  ( $\text{p}K_a = 4.20$ )?

**SOME SIMILAR PROBLEMS** 18.66–18.69 and 18.74–18.77

### Student Hot Spot

Student data indicate that you may struggle with calculating the pH of a weak acid. Access the Smartbook to view additional Learning Resources on this topic.

## The Effect of Concentration on the Extent of Acid Dissociation

If we repeat the calculation in Sample Problem 18.8, but start with a lower  $[\text{HPr}]$ , we observe a very interesting fact about the extent of dissociation of a weak acid. Suppose the initial concentration of HPr is one-tenth as much,  $0.010 \text{ M}$ , rather than

0.10 M. After filling in the reaction table and making the same assumptions, we find that

$$x = [\text{H}_3\text{O}^+] = [\text{HPr}]_{\text{dissoc}} = 3.6 \times 10^{-4} \text{ M}$$

Now, let's compare the percentages of HPr molecules dissociated at the two different initial acid concentrations, using the relationship

$$\text{Percent HA dissociated} = \frac{[\text{HA}]_{\text{dissoc}}}{[\text{HA}]_{\text{init}}} \times 100 \quad (18.5)$$

Case 1:  $[\text{HPr}]_{\text{init}} = 0.10 \text{ M}$

$$\text{Percent HPr dissociated} = \frac{1.1 \times 10^{-3} \text{ M}}{1.0 \times 10^{-1} \text{ M}} \times 100 = 1.1\%$$

Case 2:  $[\text{HPr}]_{\text{init}} = 0.010 \text{ M}$

$$\text{Percent HPr dissociated} = \frac{3.6 \times 10^{-4} \text{ M}}{1.0 \times 10^{-2} \text{ M}} \times 100 = 3.6\%$$

As the initial acid concentration decreases, the percent dissociation of the acid increases. Don't confuse the concentration of HA dissociated with the percent HA dissociated. The concentration,  $[\text{HA}]_{\text{dissoc}}$ , is lower in the diluted HA solution because the actual number of dissociated HA molecules is smaller. It is the fraction (or the percent) of dissociated HA molecules that increases with dilution.

This phenomenon is analogous to a change in container volume (pressure) for a reaction involving gases at equilibrium (Section 17.6). In the case of gases, an increase in volume shifts the equilibrium position to favor more moles of gas. In the case of HA dissociation, a lower HA concentration, which is the same as an increase in volume, shifts the equilibrium position to favor more moles of ions.

### SAMPLE PROBLEM 18.9

### Finding the Percent Dissociation of a Weak Acid

**Problem** In 2011, researchers showed that hypochlorous acid (HClO) generated by white blood cells kills bacteria. Calculate the percent dissociation of (a) 0.40 M HClO; (b) 0.035 M HClO ( $K_a = 2.9 \times 10^{-8}$ ).

**Plan** We know the  $K_a$  of HClO and need  $[\text{HClO}]_{\text{dissoc}}$  to find the percent dissociation at two different initial concentrations. We write the balanced equation and the expression for  $K_a$  and then set up a reaction table, with  $x = [\text{HClO}]_{\text{dissoc}} = [\text{ClO}^-] = [\text{H}_3\text{O}^+]$ . We assume that because HClO has a small  $K_a$ , it dissociates very little. Once  $[\text{HClO}]_{\text{dissoc}}$  is known, we use Equation 18.5 to find the percent dissociation and check the assumption.

**Solution** (a) Writing the balanced equation and the expression for  $K_a$ :

Setting up a reaction table with  $x = [\text{HClO}]_{\text{dissoc}} = [\text{ClO}^-] = [\text{H}_3\text{O}^+]$ :

Concentration (M)	HClO(aq)	+ H <sub>2</sub> O(l)	⇌	H <sub>3</sub> O <sup>+</sup> (aq)	+ ClO <sup>-</sup> (aq)
Initial	0.40	—		0	0
Change	-x	—		+x	+x
Equilibrium	0.40 - x	—		x	x

Making the assumption:  $K_a$  is small, so  $x$  is small compared with  $[\text{HClO}]_{\text{init}}$ ; therefore,  $[\text{HClO}]_{\text{init}} - x \approx [\text{HClO}]_{\text{init}}$ , or  $0.40 \text{ M} - x \approx 0.40 \text{ M}$ . Substituting into the  $K_a$  expression and solving for  $x$ :

$$K_a = \frac{[\text{ClO}^-][\text{H}_3\text{O}^+]}{[\text{HClO}]} = 2.9 \times 10^{-8} \approx \frac{(x)(x)}{0.40}$$

Thus,

$$x^2 = (0.40)(2.9 \times 10^{-8})$$

$$x = \sqrt{(0.40)(2.9 \times 10^{-8})} = 1.1 \times 10^{-4} M = [\text{HClO}]_{\text{dissoc}}$$

Finding the percent dissociation:

$$\text{Percent dissociation} = \frac{[\text{HClO}]_{\text{dissoc}}}{[\text{HClO}]_{\text{init}}} \times 100 = \frac{1.1 \times 10^{-4} M}{0.40 M} \times 100 = 0.028\%$$

Since the percent dissociation is <5%, the assumption is justified.

(b) Performing the same calculations using  $[\text{HClO}]_{\text{init}} = 0.035 M$ :

$$K_a = \frac{[\text{ClO}^-][\text{H}_3\text{O}^+]}{[\text{HClO}]} = 2.9 \times 10^{-8} \approx \frac{(x)(x)}{0.035}$$

$$x = \sqrt{(0.035)(2.9 \times 10^{-8})} = 3.2 \times 10^{-5} M = [\text{HClO}]_{\text{dissoc}}$$

Finding the percent dissociation:

$$\text{Percent dissociation} = \frac{[\text{HClO}]_{\text{dissoc}}}{[\text{HClO}]_{\text{init}}} \times 100 = \frac{3.2 \times 10^{-5} M}{0.035 M} \times 100 = 0.091\%$$

Since the percent dissociation is <5%, the assumption is justified.

**Check** The percent dissociation is very small, as we expect for an acid with such a low  $K_a$ . Note, however, that the percent dissociation is larger for the lower initial concentration, as we also expect.

### FOLLOW-UP PROBLEMS

**18.9A** Calculate the percent dissociation of 0.75 M HCN, an extremely poisonous acid that can be obtained from the pits of fruits such as cherries and apples ( $K_a = 6.2 \times 10^{-10}$ ).

**18.9B** A weak acid is 3.16% dissociated in a 1.5 M solution. What is the  $K_a$  of the acid?

**SOME SIMILAR PROBLEMS** 18.70, 18.71, 18.78, and 18.79

## The Behavior of Polyprotic Acids

Acids with more than one ionizable proton are **polyprotic acids**. In solution, each dissociation step has a different  $K_a$ . For example, phosphoric acid is a triprotic acid (three ionizable protons), so it has three  $K_a$  values:

$$K_{a1} = \frac{[\text{H}_2\text{PO}_4^-][\text{H}_3\text{O}^+]}{[\text{H}_3\text{PO}_4]} = 7.2 \times 10^{-3}$$

$$K_{a2} = \frac{[\text{HPO}_4^{2-}][\text{H}_3\text{O}^+]}{[\text{H}_2\text{PO}_4^-]} = 6.3 \times 10^{-8}$$

$$K_{a3} = \frac{[\text{PO}_4^{3-}][\text{H}_3\text{O}^+]}{[\text{HPO}_4^{2-}]} = 4.2 \times 10^{-13}$$

The relative  $K_a$  values show that  $\text{H}_3\text{PO}_4$  is a much stronger acid than  $\text{H}_2\text{PO}_4^-$ , which is much stronger than  $\text{HPO}_4^{2-}$ .

Table 18.6 (next page) lists some common polyprotic acids and their  $K_a$  values. (More are listed in Appendix C.) Note that the general pattern seen for  $\text{H}_3\text{PO}_4$  occurs for all polyprotic acids:

$$K_{a1} \gg K_{a2} \gg K_{a3}$$

This trend occurs because it is more difficult for the positively charged  $\text{H}^+$  ion to leave a singly charged anion (such as  $\text{H}_2\text{PO}_4^-$ ) than to leave a neutral molecule (such as  $\text{H}_3\text{PO}_4$ ), and more difficult still for it to leave a doubly charged anion (such as  $\text{HPO}_4^{2-}$ ). Successive  $K_a$  values typically differ by several orders of magnitude. This fact simplifies calculations because we usually neglect the  $\text{H}_3\text{O}^+$  coming from the subsequent dissociations.

**Table 18.6** Successive  $K_a$  Values for Some Polyprotic Acids at 25°C

Name (Formula)	Lewis Structure*	$K_{a1}$	$K_{a2}$	$K_{a3}$
Oxalic acid ( $\text{H}_2\text{C}_2\text{O}_4$ )		$5.6 \times 10^{-2}$	$5.4 \times 10^{-5}$	
Sulfurous acid ( $\text{H}_2\text{SO}_3$ )		$1.4 \times 10^{-2}$	$6.5 \times 10^{-8}$	
Phosphoric acid ( $\text{H}_3\text{PO}_4$ )		$7.2 \times 10^{-3}$	$6.3 \times 10^{-8}$	$4.2 \times 10^{-13}$
Arsenic acid ( $\text{H}_3\text{AsO}_4$ )		$6 \times 10^{-3}$	$1.1 \times 10^{-7}$	$3 \times 10^{-12}$
Carbonic acid ( $\text{H}_2\text{CO}_3$ )		$4.5 \times 10^{-7}$	$4.7 \times 10^{-11}$	
Hydrosulfuric acid ( $\text{H}_2\text{S}$ )		$9 \times 10^{-8}$	$1 \times 10^{-17}$	

ACID STRENGTH

**SAMPLE PROBLEM 18.10****Calculating Equilibrium Concentrations for a Polyprotic Acid**

**Problem** Ascorbic acid ( $\text{H}_2\text{C}_6\text{H}_6\text{O}_6$ ; represented as  $\text{H}_2\text{Asc}$  for this problem), known as vitamin C, is a diprotic acid ( $K_{a1} = 1.0 \times 10^{-5}$  and  $K_{a2} = 5 \times 10^{-12}$ ) found in citrus fruit. Calculate  $[\text{HAsc}^-]$ ,  $[\text{Asc}^{2-}]$ , and the pH of 0.050 M  $\text{H}_2\text{Asc}$ .

**Plan** We know the initial concentration (0.050 M) and both  $K_a$ 's for  $\text{H}_2\text{Asc}$ , and we have to calculate the equilibrium concentrations of all species and convert  $[\text{H}_3\text{O}^+]$  to pH. We first write the equations and  $K_a$  expressions. Because  $K_{a1} \gg K_{a2}$ , we can assume that the first dissociation produces almost all the  $\text{H}_3\text{O}^+$ :  $[\text{H}_3\text{O}^+]_{\text{from H}_2\text{Asc}} \gg [\text{H}_3\text{O}^+]_{\text{from HAsc}^-}$ . Also, because  $K_{a1}$  is small, the amount of  $\text{H}_2\text{Asc}$  that dissociates can be neglected. We set up a reaction table for the first dissociation, with  $x = [\text{H}_2\text{Asc}]_{\text{dissoc}}$ , and then we solve for  $[\text{H}_3\text{O}^+]$  and  $[\text{HAsc}^-]$ . Because the second dissociation occurs to a much lesser extent, we can substitute values from the first dissociation directly to find  $[\text{Asc}^{2-}]$  from the second.

**Solution** Writing the equations and  $K_a$  expressions:

$$K_{a1} = \frac{[\text{HAsc}^-][\text{H}_3\text{O}^+]}{[\text{H}_2\text{Asc}]} = 1.0 \times 10^{-5}$$

$$K_{a2} = \frac{[\text{Asc}^{2-}][\text{H}_3\text{O}^+]}{[\text{HAsc}^-]} = 5 \times 10^{-12}$$

Setting up a reaction table with  $x = [\text{H}_2\text{Asc}]_{\text{dissoc}} = [\text{HAsc}^-] \approx [\text{H}_3\text{O}^+]$ :

Concentration (M)	$\text{H}_2\text{Asc}(aq)$	+	$\text{H}_2\text{O}(l)$	$\rightleftharpoons$	$\text{H}_3\text{O}^+(aq)$	+	$\text{HAsc}^-(aq)$
Initial	0.050		—		0		0
Change	-x		—		+x		+x
Equilibrium	0.050 - x		—		x		x

Making the assumptions:

1. Because  $K_{a2} \ll K_{a1}$ ,  $[\text{H}_3\text{O}^+]_{\text{from HAsc}^-} \ll [\text{H}_3\text{O}^+]_{\text{from H}_2\text{Asc}}$ . Therefore,

$$[\text{H}_3\text{O}^+]_{\text{from H}_2\text{Asc}} \approx [\text{H}_3\text{O}^+]$$

2. Because  $K_{a1}$  is small,  $[\text{H}_2\text{Asc}]_{\text{init}} - x = [\text{H}_2\text{Asc}] \approx [\text{H}_2\text{Asc}]_{\text{init}}$ . Thus,

$$[\text{H}_2\text{Asc}] = 0.050 \text{ M} - x \approx 0.050 \text{ M}$$

Substituting into the expression for  $K_{a1}$  and solving for  $x$ :

$$K_{a1} = \frac{[\text{H}_3\text{O}^+][\text{HAsc}^-]}{[\text{H}_2\text{Asc}]} = 1.0 \times 10^{-5} = \frac{x^2}{0.050 - x} \approx \frac{x^2}{0.050}$$

$$x = [\text{HAsc}^-] \approx [\text{H}_3\text{O}^+] \approx 7.1 \times 10^{-4} \text{ M}$$

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log (7.1 \times 10^{-4}) = 3.15$$

Checking the assumptions:

1.  $[\text{H}_3\text{O}^+]_{\text{from HAsc}^-} \ll [\text{H}_3\text{O}^+]_{\text{from H}_2\text{Asc}}$ : For any second dissociation that does occur,

$$K_{a2} = \frac{[\text{H}_3\text{O}^+][\text{Asc}^{2-}]}{[\text{HAsc}^-]} = 5 \times 10^{-12} = \frac{(x)(x)}{7.1 \times 10^{-4}}$$

$$x = [\text{H}_3\text{O}^+]_{\text{from HAsc}^-} = 6 \times 10^{-8} \text{ M}$$

This is even less than  $[\text{H}_3\text{O}^+]_{\text{from H}_2\text{O}}$ , so the assumption is justified.

2.  $[\text{H}_2\text{Asc}]_{\text{dissoc}} \ll [\text{H}_2\text{Asc}]_{\text{init}}$ :  $\frac{7.1 \times 10^{-4} \text{ M}}{0.050 \text{ M}} \times 100 = 1.4\%$  (<5%; assumption is justified).

Also, note that

$$\frac{[\text{H}_2\text{Asc}]_{\text{init}}}{K_{a1}} = \frac{0.050}{1.0 \times 10^{-5}} = 5000 > 400$$

Using the equilibrium concentrations from the first dissociation to calculate  $[\text{Asc}^{2-}]$ :

$$K_{a2} = \frac{[\text{H}_3\text{O}^+][\text{Asc}^{2-}]}{[\text{HAsc}^-]} \quad \text{and} \quad [\text{Asc}^{2-}] = \frac{(K_{a2})[\text{HAsc}^-]}{[\text{H}_3\text{O}^+]}$$

$$[\text{Asc}^{2-}] = \frac{(5 \times 10^{-12})(7.1 \times 10^{-4})}{7.1 \times 10^{-4}} = 5 \times 10^{-12} \text{ M}$$

**Check**  $K_{a1} \gg K_{a2}$ , so it makes sense that  $[\text{HAsc}^-] \gg [\text{Asc}^{2-}]$  because  $\text{Asc}^{2-}$  is produced only in the second (much weaker) dissociation. Both  $K_a$ 's are small, so all concentrations except  $[\text{H}_2\text{Asc}]$  should be much lower than the original 0.050 M.

### FOLLOW-UP PROBLEMS

**18.10A** Oxalic acid ( $\text{HOOC}-\text{COOH}$ , or  $\text{H}_2\text{C}_2\text{O}_4$ ) is the simplest diprotic carboxylic acid. Its commercial uses include bleaching straw and leather and removing rust and ink stains. Calculate the equilibrium values of  $[\text{H}_2\text{C}_2\text{O}_4]$ ,  $[\text{HC}_2\text{O}_4^-]$ , and  $[\text{C}_2\text{O}_4^{2-}]$ , and find the pH of a 0.150 M  $\text{H}_2\text{C}_2\text{O}_4$  solution. Use  $K_a$  values from Appendix C. (*Hint*: First check whether you need the quadratic equation to find  $x$ .)

**18.10B** Carbonic acid ( $\text{H}_2\text{CO}_3$ ) plays a role in blood chemistry, cave formation, and ocean acidification. Using its  $K_a$  values from Appendix C, calculate the equilibrium values of  $[\text{H}_2\text{CO}_3]$ ,  $[\text{HCO}_3^-]$ , and  $[\text{CO}_3^{2-}]$ , and find the pH of a 0.075 M  $\text{H}_2\text{CO}_3$  solution.

**SOME SIMILAR PROBLEMS** 18.80 and 18.81

## Summary of Section 18.4

- Two types of weak-acid equilibrium problems involve finding  $K_a$  from a given concentration and finding a concentration from a given  $K_a$ .
- We simplify the arithmetic by assuming (1) that  $[\text{H}_3\text{O}^+]_{\text{from H}_2\text{O}}$  is much smaller than  $[\text{H}_3\text{O}^+]_{\text{from HA}}$  and can be neglected and (2) that weak acids dissociate so little that  $[\text{HA}]_{\text{init}} \approx [\text{HA}]$  at equilibrium.
- The *fraction* of weak acid molecules that dissociate is greater in a more dilute solution, even though the total  $[\text{H}_3\text{O}^+]$  is lower.
- Polyprotic acids have more than one ionizable proton, but we assume that the first dissociation provides virtually all the  $\text{H}_3\text{O}^+$ .

Electronegativity increases,  
so acidity increases.

→

	6A(16)	7A(17)
	H <sub>2</sub> O	HF $K_a = 6.8 \times 10^{-4}$
	H <sub>2</sub> S $K_{a1} = 9 \times 10^{-8}$	HCl Strong acid
	H <sub>2</sub> Se $K_{a1} = 1.3 \times 10^{-4}$	HBr Strong acid
	H <sub>2</sub> Te $K_{a1} = 2.3 \times 10^{-3}$	HI Strong acid

Bond strength decreases,  
so acidity increases.

↓

**Figure 18.9** The effect of atomic and molecular properties on nonmetal hydride acidity.

## 18.5 MOLECULAR PROPERTIES AND ACID STRENGTH

The strength of an acid depends on its ability to donate a proton, which depends in turn on the strength of the bond to the acidic proton. In this section, we apply trends in atomic and bond properties to determine the trends in acid strength of nonmetal hydrides and oxoacids and then discuss the acidity of hydrated metal ions.

### Acid Strength of Nonmetal Hydrides

Two factors determine how easily a proton is released from a nonmetal hydride:

- The electronegativity of the central nonmetal (E)
- The strength of the E—H bond

Figure 18.9 displays two periodic trends among the nonmetal hydrides:

1. *Across a period, acid strength increases.* The electronegativity of the nonmetal E determines this horizontal trend. From left to right, as E becomes more electronegative, it withdraws electron density from H, and the E—H bond becomes more polar. As a result, H<sup>+</sup> is pulled away more easily by an O atom of a water molecule. In aqueous solution, the hydrides of Groups 3A(13) to 5A(15) do not behave as acids, but an increase in acid strength is seen from Group 6A(16) to 7A(17).

2. *Down a group, acid strength increases.* E—H bond strength determines this vertical trend. As E becomes larger, the E—H bond becomes longer and weaker, so H<sup>+</sup> comes off more easily.\* For example, hydrohalic acid strength increases down Group 7A(17):

Acid strength:	HF	<<	HCl	<	HBr	<	HI
Bond length (pm):	92		127		141		161
Bond energy (kJ/mol):	565		427		363		295

(This trend is not seen in aqueous solution, where HCl, HBr, and HI are all equally strong; we discuss how it is observed in Section 18.8.)

### Acid Strength of Oxoacids

All oxoacids have the acidic H atom bonded to an O atom, so bond length is not involved. As we mentioned for the halogen oxoacids (Section 14.9), two other factors determine the acid strength of oxoacids:

- The electronegativity of the central nonmetal (E)
- The number of O atoms around E (related to the oxidation number, O.N., of E)

Figure 18.10 summarizes these trends:

1. *For oxoacids with the same number of O atoms, acid strength increases with the electronegativity of E.* Consider the hypohalous acids (HOE, where E is a halogen atom). The more electronegative E is, the more polar the O—H bond becomes and the more easily H<sup>+</sup> is lost (Figure 18.10A). Electronegativity (EN) decreases down a group, as does acid strength:

$K_a$ of HOCl = $2.9 \times 10^{-8}$	$K_a$ of HOBr = $2.3 \times 10^{-9}$	$K_a$ of HOI = $2.3 \times 10^{-11}$
EN of Cl = 3.5	EN of Br = 2.8	EN of I = 2.5

Similarly, in Group 6A(16), H<sub>2</sub>SO<sub>4</sub> (EN of S = 2.5) is stronger than H<sub>2</sub>SeO<sub>4</sub> (EN of Se = 2.4); in Group 5A(15), H<sub>3</sub>PO<sub>4</sub> (EN of P = 2.1) is stronger than H<sub>3</sub>AsO<sub>4</sub> (EN of As = 2.0), and so forth.

2. *For oxoacids with different numbers of O atoms, acid strength increases with the number of O atoms (or with the O.N. of the central nonmetal).* The electronegative O atoms pull electron density away from E, which makes the O—H bond more polar. The

\*Actually, bond energy refers to bond breakage that forms an H atom, whereas acidity refers to bond breakage that forms an H<sup>+</sup> ion. Although these two types of bond breakage are not the same, the trends in bond energy and acid strength are opposites.

**Figure 18.10** The relative strengths of oxoacids. A, Cl withdraws electron density (thickness of green arrow) from the O—H bond most effectively, making that bond most polar (relative size of  $\delta$  symbols). B, Additional O atoms pull more electron density from the O—H bond.

more O atoms present, the greater the shift in electron density, and the more easily the  $\text{H}^+$  ion comes off (Figure 18.10B). Therefore, the chlorine oxoacids ( $\text{HOClO}_n$ , with  $n$  from 0 to 3) increase in strength with the number of O atoms (and the O.N. of Cl):

$$K_a \text{ of HOCl} = 2.9 \times 10^{-8} \quad K_a \text{ of HOClO} = 1.12 \times 10^{-2} \quad K_a \text{ of HOClO}_2 \approx 1 \quad K_a \text{ of HOClO}_3 > 10^7$$

Similarly,  $\text{HNO}_3$  is stronger than  $\text{HNO}_2$ ,  $\text{H}_2\text{SO}_4$  is stronger than  $\text{H}_2\text{SO}_3$ , and so forth.

## Acidity of Hydrated Metal Ions

The aqueous solutions of certain metal ions are acidic because the *hydrated* metal ion transfers an  $\text{H}^+$  ion to water. Consider a general metal nitrate,  $\text{M}(\text{NO}_3)_n$ , as it dissolves in water. The ions separate and the metal ion becomes bonded to some number of  $\text{H}_2\text{O}$  molecules. This equation shows the hydration of the cation ( $\text{M}^{n+}$ ) using  $\text{H}_2\text{O}$  molecules and “(aq)”; hydration of the anion ( $\text{NO}_3^-$ ) is indicated with just “(aq)”:

If the metal ion,  $\text{M}^{n+}$ , is *small and highly charged*, its high charge density withdraws sufficient electron density from the O—H bonds of the bound water molecules for an  $\text{H}^+$  to be released. Thus, the hydrated cation,  $\text{M}(\text{H}_2\text{O})_x^{n+}$ , is a typical Brønsted-Lowry acid. The bound  $\text{H}_2\text{O}$  that releases the  $\text{H}^+$  becomes a bound  $\text{OH}^-$  ion:

Salts of most  $\text{M}^{2+}$  and  $\text{M}^{3+}$  ions yield acidic aqueous solutions. The  $K_a$  values for some acidic hydrated metal ions appear in Appendix C.

Consider the small, highly charged  $\text{Al}^{3+}$  ion. When an aluminum salt, such as  $\text{Al}(\text{NO}_3)_3$ , dissolves in water, the following steps occur:

Note the formulas of the hydrated metal ions in the last step. When  $\text{H}^+$  is released, the number of bound  $\text{H}_2\text{O}$  molecules decreases by 1 (from 6 to 5) and the number of bound  $\text{OH}^-$  ions increases by 1 (from 0 to 1), which reduces the ion’s positive charge by 1 (from 3 to 2) (Figure 18.11). This pattern of changes in the formula of the hydrated metal ion before and after it loses a proton occurs with any highly charged metal ion in water.

**Figure 18.11** The acidic behavior of the hydrated  $\text{Al}^{3+}$  ion. The hydrated  $\text{Al}^{3+}$  ion is small and highly charged and pulls electron density from the O—H bonds, so an  $\text{H}^+$  ion can be transferred to a nearby water molecule.

## › Summary of Section 18.5

- › For nonmetal hydrides, acid strength increases across a period, with the electronegativity of the nonmetal (E), and down a group, with the length of the E—H bond.
- › For oxoacids with the same number of O atoms, acid strength increases with electronegativity of E; for oxoacids with the same E, acid strength increases with number of O atoms (or O.N. of E).
- › Small, highly charged metal ions are acidic in water because they withdraw electron density from the O—H bonds of bound H<sub>2</sub>O molecules, releasing an H<sup>+</sup> ion to the solution.

## 18.6 WEAK BASES AND THEIR RELATION TO WEAK ACIDS

The Brønsted-Lowry concept expands the definition of a base to encompass a host of species that the Arrhenius definition excludes: *to accept a proton, a base needs only a lone electron pair.*

Let's examine the equilibrium system of a weak base (B) as it dissolves in water: B accepts a proton from H<sub>2</sub>O, which acts as an acid, leaving behind an OH<sup>−</sup> ion:

This general reaction for a base in water is described by the equilibrium expression

$$K_c = \frac{[\text{BH}^+][\text{OH}^-]}{[\text{B}][\text{H}_2\text{O}]}$$

Based on our earlier reasoning, we eliminate [H<sub>2</sub>O] from the equilibrium expression and obtain the **base-dissociation constant** (or **base-ionization constant**),  $K_b$ :

$$K_b = \frac{[\text{BH}^+][\text{OH}^-]}{[\text{B}]} \quad (18.6)$$

Despite the name “base-dissociation constant,” *no base dissociates in the process.*

Base-dissociation constants can be expressed as p*K*<sub>b</sub> values:

$$\text{p}K_b = -\log K_b \quad \text{and} \quad 10^{-\text{p}K_b} = K_b$$

The larger the value of  $K_b$ , the smaller the value of p*K*<sub>b</sub> and the stronger the base, producing a higher [OH<sup>−</sup>] at equilibrium:

$$\text{stronger base} \implies \text{higher } [\text{OH}^-] \implies \text{larger } K_b \text{ (lower p}K_b\text{)}$$

In aqueous solution, the two large classes of weak bases are (1) the molecular species ammonia and the amines and (2) the anions of weak acids.

### Molecules as Weak Bases: Ammonia and the Amines

Ammonia is the simplest N-containing compound that acts as a weak base in water:

Despite labels on reagent bottles that read “ammonium hydroxide,” an aqueous solution of ammonia consists largely of water and *unprotonated* NH<sub>3</sub> molecules, as its small  $K_b$  indicates. In a 1.0 M NH<sub>3</sub> solution, for example, [OH<sup>−</sup>] = [NH<sub>4</sub><sup>+</sup>] = 4.2 × 10<sup>−3</sup> M, so about 99.6% of the NH<sub>3</sub> is not protonated. Table 18.7 shows the  $K_b$  values for a few molecular bases. (A more extensive list appears in Appendix C.)

If one or more of the H atoms in ammonia is replaced by an organic group (designated as R), an *amine* results: RNH<sub>2</sub>, R<sub>2</sub>NH, or R<sub>3</sub>N (Section 15.4; see Figure 15.17). The key structural feature of these organic compounds, as in all Brønsted-Lowry bases, is *a lone pair of electrons that can bind the proton donated by the acid.* Figure 18.12 depicts this process for methylamine, the simplest amine.

To find the pH of a solution of a molecular weak base, we use an approach very similar to that for a weak acid: write the equilibrium expression, set up a reaction

Table 18.7  $K_b$  Values for Some Molecular (Amine) Bases at 25°C

Name (Formula)	Lewis Structure*	Reaction	$K_b$	$pK_b$
Diethylamine $[(CH_3CH_2)_2NH]$		$(CH_3CH_2)_2NH(aq) + H_2O(l) \rightleftharpoons (CH_3CH_2)_2NH_2^+(aq) + OH^-(aq)$	$8.6 \times 10^{-4}$	3.07
Dimethylamine $[(CH_3)_2NH]$		$(CH_3)_2NH(aq) + H_2O(l) \rightleftharpoons (CH_3)_2NH_2^+(aq) + OH^-(aq)$	$5.9 \times 10^{-4}$	3.23
Methylamine $(CH_3NH_2)$		$CH_3NH_2(aq) + H_2O(l) \rightleftharpoons CH_3NH_3^+(aq) + OH^-(aq)$	$4.4 \times 10^{-4}$	3.36
Ammonia $(NH_3)$		$NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$	$1.76 \times 10^{-5}$	4.75
Pyridine $(C_5H_5N)$		$C_5H_5N(aq) + H_2O(l) \rightleftharpoons C_5H_5NH^+(aq) + OH^-(aq)$	$1.7 \times 10^{-9}$	8.77
Aniline $(C_6H_5NH_2)$		$C_6H_5NH_2(aq) + H_2O(l) \rightleftharpoons C_6H_5NH_3^+(aq) + OH^-(aq)$	$4.0 \times 10^{-10}$	9.40

Figure 18.12 Abstraction of a proton from water by the base methylamine.

table to find  $[B]_{\text{reacting}}$ , make the usual assumptions, and then solve for  $[OH^-]$ . The only additional step is to convert  $[OH^-]$  to  $[H_3O^+]$  in order to calculate pH.

## SAMPLE PROBLEM 18.11

Determining pH from  $K_b$  and Initial  $[B]$ 

**Problem** Dimethylamine,  $(CH_3)_2NH$  (see the space-filling model), a key intermediate in detergent manufacture, has a  $K_b$  of  $5.9 \times 10^{-4}$ . What is the pH of 1.5 M  $(CH_3)_2NH$ ?

**Plan** We know the initial concentration (1.5 M) and  $K_b$  ( $5.9 \times 10^{-4}$ ) of  $(CH_3)_2NH$  and have to find the pH. The amine reacts with water to form  $OH^-$ , so we have to find  $[OH^-]$  and then calculate  $[H_3O^+]$  and pH. We first write the balanced equation and  $K_b$  expression. Because  $K_b \gg K_w$ , the  $[OH^-]$  from the autoionization of water is negligible, so we disregard it and assume that all the  $[OH^-]$  comes from the base reacting with water. Because  $K_b$  is small, we assume that the amount of amine reacting,  $[(CH_3)_2NH]_{\text{reacting}}$ , can be neglected. We set up a reaction table, make the assumption, and solve for  $x$ . Then we check the assumption and convert  $[OH^-]$  to  $[H_3O^+]$  using  $K_w$ ; finally, we calculate pH.

**Solution** Writing the balanced equation and  $K_b$  expression:

$$K_b = \frac{[(CH_3)_2NH_2^+][OH^-]}{[(CH_3)_2NH]}$$

Dimethylamine

Setting up the reaction table, with  $x = [(\text{CH}_3)_2\text{NH}]_{\text{reacting}} = [(\text{CH}_3)_2\text{NH}_2^+] = [\text{OH}^-]$ :

Concentration (M)	$(\text{CH}_3)_2\text{NH}(aq)$	$+ \text{H}_2\text{O}(l)$	$\rightleftharpoons$	$(\text{CH}_3)_2\text{NH}_2^+(aq)$	$+ \text{OH}^-(aq)$
Initial	1.5	—		0	0
Change	$-x$	—		$+x$	$+x$
Equilibrium	$1.5 - x$	—		$x$	$x$

Making the assumption:  $K_b$  is small, so

$$[(\text{CH}_3)_2\text{NH}]_{\text{init}} - [(\text{CH}_3)_2\text{NH}]_{\text{reacting}} = [(\text{CH}_3)_2\text{NH}] \approx [(\text{CH}_3)_2\text{NH}]_{\text{init}}$$

Thus,  $1.5 M - x \approx 1.5 M$ .

Substituting into the  $K_b$  expression and solving for  $x$ :

$$K_b = \frac{[(\text{CH}_3)_2\text{NH}_2^+][\text{OH}^-]}{[(\text{CH}_3)_2\text{NH}]} = 5.9 \times 10^{-4} \approx \frac{x^2}{1.5}$$

$$x = [\text{OH}^-] \approx 3.0 \times 10^{-2} M$$

Checking the assumption:

$$\frac{3.0 \times 10^{-2} M}{1.5 M} \times 100 = 2.0\% (< 5\%; \text{assumption is justified.})$$

Note that the Comment in Sample Problem 18.8 applies in these cases as well:

$$\frac{[\text{B}]_{\text{init}}}{K_b} = \frac{1.5}{5.9 \times 10^{-4}} = 2.5 \times 10^3 > 400$$

Calculating pH:

$$[\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{3.0 \times 10^{-2}} = 3.3 \times 10^{-13} M$$

$$\text{pH} = -\log(3.3 \times 10^{-13}) = 12.48$$

**Check** The value of  $x$  seems reasonable:  $\sqrt{(\sim 6 \times 10^{-4})(1.5)} = \sqrt{9 \times 10^{-4}} = 3 \times 10^{-2}$ . Because  $(\text{CH}_3)_2\text{NH}$  is a weak base, the pH should be several pH units above 7.

**Comment** Alternatively, we can find the pOH first and then the pH:

$$\text{pOH} = -\log[\text{OH}^-] = -\log(3.0 \times 10^{-2}) = 1.52$$

$$\text{pH} = 14 - \text{pOH} = 14 - 1.52 = 12.48$$

Pyridine

### FOLLOW-UP PROBLEMS

**18.11A** Pyridine ( $\text{C}_5\text{H}_5\text{N}$ , see the space-filling model) serves as a solvent and a base in many organic syntheses. It has a  $\text{p}K_b$  of 8.77. What is the pH of 0.10 M pyridine?

**18.11B** The weak base amphetamine,  $\text{C}_6\text{H}_5\text{CH}_2\text{CH}(\text{CH}_3)\text{NH}_2$ , is a stimulant used to treat narcolepsy and attention deficit disorder. What is the pH of 0.075 M amphetamine ( $K_b = 6.3 \times 10^{-5}$ )?

**SOME SIMILAR PROBLEMS** 18.103–18.106

## Anions of Weak Acids as Weak Bases

The other large group of Brønsted-Lowry bases consists of anions of weak acids:\*

For example,  $\text{F}^-$ , the anion of the weak acid HF, is a weak base:

\*This equation and equilibrium expression are sometimes referred to as a *hydrolysis reaction* and a *hydrolysis constant*,  $K_h$ , because water is dissociated (hydrolyzed). Actually, except for the charge on the base, this process is the same as the proton-abstraction process by ammonia and amines. That is,  $K_h$  is just another symbol for  $K_b$ , so we'll use  $K_b$  throughout.

Why is a solution of HA acidic and a solution of  $A^-$  basic? We'll find the answer from relative concentrations of species in 1 M HF and in 1 M NaF:

1. *The acidity of HA(aq).* HF is a weak acid, so the equilibrium position of the acid dissolving in water lies far to the left:

Water also contributes  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$ , but their concentrations are extremely small:

Of all the species present—HF,  $\text{H}_2\text{O}$ ,  $\text{H}_3\text{O}^+$ ,  $\text{F}^-$ , and  $\text{OH}^-$ —the two that can influence the acidity of the solution are  $\text{H}_3\text{O}^+$ , predominantly from HF, and  $\text{OH}^-$  from water. Thus, the HF solution is acidic because  $[\text{H}_3\text{O}^+]_{\text{from HF}} \gg [\text{OH}^-]_{\text{from H}_2\text{O}}$ .

2. *The basicity of  $A^-(aq)$ .* Now, consider the species present in 1 M NaF. The salt dissociates completely to yield 1 M  $\text{Na}^+$  and 1 M  $\text{F}^-$ . The  $\text{Na}^+$  behaves as a spectator ion, while some  $\text{F}^-$  reacts as a weak base to produce small amounts of HF and  $\text{OH}^-$ :

As before, water dissociation contributes minute amounts of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$ . Thus, in addition to the  $\text{Na}^+$  ion, the species present are the same as in the HF solution: HF,  $\text{H}_2\text{O}$ ,  $\text{H}_3\text{O}^+$ ,  $\text{F}^-$ , and  $\text{OH}^-$ . The two species that affect the acidity are  $\text{OH}^-$ , predominantly from  $\text{F}^-$  reacting with water, and  $\text{H}_3\text{O}^+$  from water. In this case,  $[\text{OH}^-]_{\text{from F}^-} \gg [\text{H}_3\text{O}^+]_{\text{from H}_2\text{O}}$ , so the solution is basic.

To summarize,

- In an HA solution,  $[\text{HA}] \gg [\text{A}^-]$  and  $[\text{H}_3\text{O}^+]_{\text{from HA}} \gg [\text{OH}^-]_{\text{from H}_2\text{O}}$ , so the solution is acidic.
- In an  $\text{A}^-$  solution,  $[\text{A}^-] \gg [\text{HA}]$  and  $[\text{OH}^-]_{\text{from A}^-} \gg [\text{H}_3\text{O}^+]_{\text{from H}_2\text{O}}$ , so the solution is basic.

## The Relation Between $K_a$ and $K_b$ of a Conjugate Acid-Base Pair

A key relationship exists between the  $K_a$  of HA and the  $K_b$  of its conjugate base,  $\text{A}^-$ , which we can see by writing the two reactions as a reaction sequence and adding them:

*The sum of the two dissociation reactions is the autoionization of water.* Recall from Chapter 17 that, for a reaction that is the *sum* of two or more reactions, the overall equilibrium constant is the *product* of the individual equilibrium constants. Therefore, writing the equilibrium expressions for each reaction gives

$$\frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} \times \frac{[\text{HA}][\text{OH}^-]}{[\text{A}^-]} = [\text{H}_3\text{O}^+][\text{OH}^-]$$

or

$$K_a(\text{of HA}) \times K_b(\text{of A}^-) = K_w \quad (18.7)$$

This relationship allows us to find  $K_a$  of the acid in a conjugate pair given  $K_b$  of the base, and vice versa. Reference tables typically have  $K_a$  and  $K_b$  values for *molecular species only*. The  $K_b$  for  $\text{F}^-$  and the  $K_a$  for  $\text{CH}_3\text{NH}_3^+$ , for example, do not appear in standard tables, but you can calculate them by looking up the value for the molecular conjugate species and relating it to  $K_w$ . To find the  $K_b$  value for  $\text{F}^-$ , for instance, we look up the  $K_a$  value for HF and apply Equation 18.7:

$$K_a \text{ of HF} = 6.8 \times 10^{-4} \text{ (from Appendix C)}$$

So, we have

$$K_a \text{ of HF} \times K_b \text{ of F}^- = K_w$$

or

$$K_b \text{ of F}^- = \frac{K_w}{K_a \text{ of HF}} = \frac{1.0 \times 10^{-14}}{6.8 \times 10^{-4}} = 1.5 \times 10^{-11}$$

## SAMPLE PROBLEM 18.12

Determining the pH of a Solution of  $A^-$ 

**Problem** Sodium acetate ( $\text{CH}_3\text{COONa}$ , represented by  $\text{NaAc}$  for this problem) is used in textile dyeing. What is the pH of 0.25 M  $\text{NaAc}$  at  $25^\circ\text{C}$ ? The  $K_a$  of acetic acid ( $\text{HAc}$ ) is  $1.8 \times 10^{-5}$ .

**Plan** We know the initial concentration of  $\text{Ac}^-$  (0.25 M) and the  $K_a$  of  $\text{HAc}$  ( $1.8 \times 10^{-5}$ ), and we have to find the pH of the  $\text{Ac}^-$  solution, knowing that  $\text{Ac}^-$  acts as a weak base in water. We write the base-dissociation equation and  $K_b$  expression. If we can find  $[\text{OH}^-]$ , we can use  $K_w$  to find  $[\text{H}_3\text{O}^+]$  and convert it to pH. To solve for  $[\text{OH}^-]$ , we need the  $K_b$  of  $\text{Ac}^-$ , which we obtain from the  $K_a$  of its conjugate acid  $\text{HAc}$  by applying Equation 18.7. We set up a reaction table to find  $[\text{OH}^-]$  and make the usual assumption that  $K_b$  is small, so  $[\text{Ac}^-]_{\text{init}} \approx [\text{Ac}^-]$ . Notice that  $\text{Na}^+$  is a spectator ion and is not included in the base-dissociation equation.

**Solution** Writing the base-dissociation equation and  $K_b$  expression:

Setting up the reaction table, with  $x = [\text{Ac}^-]_{\text{reacting}} = [\text{HAc}] = [\text{OH}^-]$ :

Concentration (M)	$\text{Ac}^-(aq)$	+	$\text{H}_2\text{O}(l)$	$\rightleftharpoons$	$\text{HAc}(aq)$	+	$\text{OH}^-(aq)$
Initial	0.25		—		0		0
Change	$-x$		—		$+x$		$+x$
Equilibrium	$0.25 - x$		—		$x$		$x$

Solving for  $K_b$  of  $\text{Ac}^-$ :

$$K_b = \frac{K_w}{K_a} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

Making the assumption: Because  $K_b$  is small,  $0.25 M - x \approx 0.25 M$ .

Substituting into the expression for  $K_b$  and solving for  $x$ :

$$K_b = \frac{[\text{HAc}][\text{OH}^-]}{[\text{Ac}^-]} = 5.6 \times 10^{-10} \approx \frac{x^2}{0.25} \quad x = [\text{OH}^-] \approx 1.2 \times 10^{-5} M$$

Checking the assumption:

$$\frac{1.2 \times 10^{-5} M}{0.25 M} \times 100 = 4.8 \times 10^{-3} \% (< 5\%; \text{assumption is justified.})$$

Also note that  $\frac{0.25}{5.6 \times 10^{-10}} = 4.5 \times 10^8 > 400$

Solving for pH:

$$[\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{1.2 \times 10^{-5}} = 8.3 \times 10^{-10} M$$

$$\text{pH} = -\log(8.3 \times 10^{-10}) = 9.08$$

**Check** The  $K_b$  calculation seems reasonable:  $\sim 10 \times 10^{-15} / 2 \times 10^{-5} = 5 \times 10^{-10}$ . Because  $\text{Ac}^-$  is a weak base,  $[\text{OH}^-] > [\text{H}_3\text{O}^+]$ ; thus,  $\text{pH} > 7$ , which makes sense.

## FOLLOW-UP PROBLEMS

**18.12A** Sodium hypochlorite ( $\text{NaClO}$ ) is the active ingredient in household laundry bleach. What is the pH of 0.20 M  $\text{NaClO}$ ?

**18.12B** Sodium nitrite ( $\text{NaNO}_2$ ) is added to cured meats such as bacon to prevent growth of bacteria. What is the pH of 0.80 M  $\text{NaNO}_2$ ?

**SOME SIMILAR PROBLEMS** 18.111–18.114

## Student Hot Spot

Student data indicate that you may struggle with pH calculations involving weakly basic anions. Access the Smartbook to view additional Learning Resources on this topic.

## › Summary of Section 18.6

- › The extent to which a weak base accepts a proton from water to form  $\text{OH}^-$  is expressed by a base-dissociation constant,  $K_b$ .
- › Brønsted-Lowry bases include  $\text{NH}_3$  and amines and the anions of weak acids. All produce basic solutions by accepting  $\text{H}^+$  from water, which yields  $\text{OH}^-$ , thus making  $[\text{H}_3\text{O}^+] < [\text{OH}^-]$ .
- › A solution of HA is acidic because  $[\text{HA}] \gg [\text{A}^-]$ , so  $[\text{H}_3\text{O}^+] > [\text{OH}^-]$ . A solution of  $\text{A}^-$  is basic because  $[\text{A}^-] \gg [\text{HA}]$ , so  $[\text{OH}^-] > [\text{H}_3\text{O}^+]$ .
- › By multiplying the expressions for  $K_a$  of HA and  $K_b$  of  $\text{A}^-$ , we obtain  $K_w$ . This relationship allows us to calculate either  $K_a$  of  $\text{BH}^+$  or  $K_b$  of  $\text{A}^-$ .

## 18.7 ACID-BASE PROPERTIES OF SALT SOLUTIONS

In many cases, when a salt dissolves, one or both of its ions may react with water and affect the pH of the solution. You've seen that cations of weak bases (such as  $\text{NH}_4^+$ ) are acidic, anions of weak acids (such as  $\text{CN}^-$ ) are basic, and small, highly charged metal cations (such as  $\text{Al}^{3+}$ ) are acidic. In addition, certain ions (such as  $\text{H}_2\text{PO}_4^-$  and  $\text{HCO}_3^-$ ) can act as an acid or a base. In this section, we classify the acid-base behavior of the various types of salt solutions.

### Salts That Yield Neutral Solutions

*A salt consisting of the anion of a strong acid and the cation of a strong base yields a neutral solution because the ions do not react with water.* When a strong acid such as  $\text{HNO}_3$  dissolves, the reaction goes essentially to completion because *the anion of a strong acid is a much weaker base than water.* The anion, in this case  $\text{NO}_3^-$ , is hydrated, but *it does not react with water:*

Similarly, a strong base, such as  $\text{NaOH}$ , dissolves completely. The cation, in this case  $\text{Na}^+$ , is hydrated, but *it is not small and charged enough to react with water:*

The ions that do not react with water are:

- the anions of the strong hydrohalic acids:  $\text{Cl}^-$ ,  $\text{Br}^-$ ,  $\text{I}^-$ ;
- the ions of strong oxoacids, such as  $\text{NO}_3^-$  and  $\text{ClO}_4^-$ ;
- the Group 1A(1) ions (cations of strong bases); and
- $\text{Ca}^{2+}$ ,  $\text{Sr}^{2+}$ , and  $\text{Ba}^{2+}$  in Group 2A(2) (cations of strong bases).

*Salts containing only these anions and cations yield neutral solutions.* The salts  $\text{LiNO}_3$  and  $\text{CaCl}_2$  are two examples.

### Salts That Yield Acidic Solutions

There are two types of salts that yield acidic solutions; in both types, the cation is responsible for the acidity:

1. *A salt consisting of the cation of a weak base and the anion of a strong acid yields an acidic solution because the cation acts as a weak acid, and the anion does not react.* For example,  $\text{NH}_4\text{Cl}$  yields an acidic solution because  $\text{NH}_4^+$ , the cation of the weak base  $\text{NH}_3$ , is a weak acid;  $\text{Cl}^-$ , the anion of the strong  $\text{HCl}$ , does not react:

2. *A salt consisting of a small, highly charged metal cation and the anion of a strong acid yields an acidic solution because the cation acts as a weak acid (see Figure 18.11), and the anion does not react.* For example,  $\text{Fe}(\text{NO}_3)_3$  yields an acidic

solution because the hydrated  $\text{Fe}^{3+}$  ion is a weak acid;  $\text{NO}_3^-$ , the anion of the strong  $\text{HNO}_3$ , does not react:

## Salts That Yield Basic Solutions

A salt consisting of the anion of a weak acid and the cation of a strong base yields a basic solution because the anion acts as a weak base, and the cation does not react. Sodium acetate, for example, yields a basic solution because the  $\text{CH}_3\text{COO}^-$  ion, the anion of the weak acid  $\text{CH}_3\text{COOH}$ , acts as a weak base;  $\text{Na}^+$ , the cation of the strong base  $\text{NaOH}$ , does not react:

### SAMPLE PROBLEM 18.13

### Predicting Relative Acidity of Salt Solutions from Reactions of the Ions with Water

**Problem** Predict whether aqueous solutions of the following salts are acidic, basic, or neutral, and write an equation for the reaction of any ion with water:

- (a) Potassium perchlorate,  $\text{KClO}_4$       (b) Sodium benzoate,  $\text{C}_6\text{H}_5\text{COONa}$   
 (c) Chromium(III) nitrate,  $\text{Cr}(\text{NO}_3)_3$

**Plan** The formula shows the cation and the anion. Depending on an ion's ability to react with water, the solution will be neutral (strong-acid anion and strong-base cation), acidic (weak-base cation or highly charged metal cation with strong-acid anion), or basic (weak-acid anion and strong-base cation).

**Solution** (a) **Neutral.** The ions are  $\text{K}^+$  and  $\text{ClO}_4^-$ . The  $\text{K}^+$  is from the strong base  $\text{KOH}$ , and the  $\text{ClO}_4^-$  is from the strong acid  $\text{HClO}_4$ . Neither ion reacts with water.

(b) **Basic.** The ions are  $\text{Na}^+$  and  $\text{C}_6\text{H}_5\text{COO}^-$ . The  $\text{Na}^+$  is the cation of the strong base  $\text{NaOH}$ , so it does not react with water. The benzoate ion,  $\text{C}_6\text{H}_5\text{COO}^-$ , is the anion of the weak acid benzoic acid, so it reacts with water to produce  $\text{OH}^-$  ion:

(c) **Acidic.** The ions are  $\text{Cr}^{3+}$  and  $\text{NO}_3^-$ . The  $\text{NO}_3^-$  is the anion of the strong acid  $\text{HNO}_3$ , so it does not react with water. The  $\text{Cr}^{3+}$  ion is small and highly charged, so the hydrated ion,  $\text{Cr}(\text{H}_2\text{O})_6^{3+}$ , reacts with water to produce  $\text{H}_3\text{O}^+$ :

### FOLLOW-UP PROBLEMS

**18.13A** Write equations to predict whether solutions of the following salts are acidic, basic, or neutral: (a)  $\text{KClO}_2$ ; (b)  $\text{CH}_3\text{NH}_3\text{NO}_3$ ; (c)  $\text{RbBr}$ .

**18.13B** Write equations to predict whether solutions of the following salts are acidic, basic, or neutral: (a)  $\text{FeBr}_3$ ; (b)  $\text{Ca}(\text{NO}_2)_2$ ; (c)  $\text{C}_6\text{H}_5\text{NH}_3\text{I}$ .

**SOME SIMILAR PROBLEMS** 18.120, 18.121(a), 18.122, 18.123(a), 18.123(b), 18.124, 18.125(c), 18.126(c), and 18.127(c)

### Student Hot Spot

Student data indicate that you may struggle with predicting the pH of a salt solution. Access the Smartbook to view additional Learning Resources on this topic.

## Salts of Weakly Acidic Cations and Weakly Basic Anions

If a salt consists of a cation that is a weak acid *and* an anion that is a weak base, the overall acidity of the solution depends on the relative acid strength ( $K_a$ ) and base strength ( $K_b$ ) of the separated ions. Consider a solution of ammonium cyanide,  $\text{NH}_4\text{CN}$ , and the reactions that occur between the separated ions and water. Ammonium ion is the conjugate acid of a weak base, so it is a weak acid:

Cyanide ion is the anion of a weak acid, so it is a weak base:

The reaction that goes farther to the right determines the pH of the solution, so we compare the  $K_a$  of  $\text{NH}_4^+$  with the  $K_b$  of  $\text{CN}^-$ . Only molecular compounds are listed

in  $K_a$  and  $K_b$  tables, so we use Equation 18.7 to calculate these values for the two ions:

$$K_a \text{ of } \text{NH}_4^+ = \frac{K_w}{K_b \text{ of } \text{NH}_3} = \frac{1.0 \times 10^{-14}}{1.76 \times 10^{-5}} = 5.7 \times 10^{-10}$$

$$K_b \text{ of } \text{CN}^- = \frac{K_w}{K_a \text{ of } \text{HCN}} = \frac{1.0 \times 10^{-14}}{6.2 \times 10^{-10}} = 1.6 \times 10^{-5}$$

Because  $K_b$  of  $\text{CN}^- > K_a$  of  $\text{NH}_4^+$ , we know that  $\text{CN}^-$  is a stronger base than  $\text{NH}_4^+$  is an acid. Thus, more  $\text{OH}^-$  than  $\text{H}_3\text{O}^+$  is produced, and the  $\text{NH}_4\text{CN}$  solution is basic.

## Salts of Amphiprotic Anions

The only salts left to consider are those in which the cation comes from a strong base and therefore does not react with water, and the anion comes from a polyprotic acid with one or more ionizable protons still attached. These anions are amphiprotic—they can act as an acid and release a proton *to* water or as a base and abstract a proton *from* water. As in the previous case, to determine the overall acidity of their solutions, we compare the magnitudes of  $K_a$  and  $K_b$ , but here we compare the  $K_a$  and  $K_b$  of the *same* species, the anion.

For example,  $\text{Na}_2\text{HPO}_4$  consists of  $\text{Na}^+$ , the cation of a strong base, which does not react with water, and  $\text{HPO}_4^{2-}$ , the second anion of the weak polyprotic acid  $\text{H}_3\text{PO}_4$ . In water, the salt undergoes three steps:

- $\text{Na}_2\text{HPO}_4(s) \xrightarrow{\text{H}_2\text{O}} 2\text{Na}^+(aq) + \text{HPO}_4^{2-}(aq)$  [dissolution and hydration]
- $\text{HPO}_4^{2-}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{PO}_4^{3-}(aq) + \text{H}_3\text{O}^+(aq)$  [acting as a weak acid]
- $\text{HPO}_4^{2-}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_2\text{PO}_4^-(aq) + \text{OH}^-(aq)$  [acting as a weak base]

We must decide whether step 2 or step 3 goes farther to the right. Appendix C lists the  $K_a$  of  $\text{HPO}_4^{2-}$  as  $4.2 \times 10^{-13}$ , but the  $K_b$  of  $\text{HPO}_4^{2-}$  is not given, so we find it from the  $K_a$  of its conjugate acid,  $\text{H}_2\text{PO}_4^-$ , using Equation 18.7:

$$K_b \text{ of } \text{HPO}_4^{2-} = \frac{K_w}{K_a \text{ of } \text{H}_2\text{PO}_4^-} = \frac{1.0 \times 10^{-14}}{6.3 \times 10^{-8}} = 1.6 \times 10^{-7}$$

Because  $K_b$  ( $1.6 \times 10^{-7}$ )  $>$   $K_a$  ( $4.2 \times 10^{-13}$ ),  $\text{HPO}_4^{2-}$  is stronger as a base than as an acid, so a solution of  $\text{Na}_2\text{HPO}_4$  is basic.

Table 18.8 displays the acid-base behavior of the various types of salts in water.

Table 18.8 The Acid-Base Behavior of Salts in Water			
Nature of Ions	Examples	Ion(s) That React(s) with Water: Example(s)	pH
<b>Neutral</b>			
Cation of strong base	NaCl, KBr, $\text{Ba}(\text{NO}_3)_2$	None	7.0
Anion of strong acid			
<b>Acidic</b>			
Cation of weak base	$\text{NH}_4\text{Cl}$ , $\text{NH}_4\text{NO}_3$ , $\text{CH}_3\text{NH}_3\text{Br}$	Cation: $\text{NH}_4^+ + \text{H}_2\text{O} \rightleftharpoons \text{NH}_3 + \text{H}_3\text{O}^+$	$<7.0$
Anion of strong acid			
Small, highly charged metal cation	$\text{Al}(\text{NO}_3)_3$ , $\text{CrBr}_3$ , $\text{FeCl}_3$	Cation: $\text{Al}(\text{H}_2\text{O})_6^{3+} + \text{H}_2\text{O} \rightleftharpoons \text{Al}(\text{H}_2\text{O})_5\text{OH}^{2+} + \text{H}_3\text{O}^+$	$<7.0$
Anion of strong acid			
<b>Basic</b>			
Cation of strong base	$\text{KNO}_2$ , $\text{NaClO}$ , $\text{Na}_2\text{CO}_3$	Anion: $\text{NO}_2^- + \text{H}_2\text{O} \rightleftharpoons \text{HNO}_2 + \text{OH}^-$	$>7.0$
Anion of weak acid			
<b>Acidic/Basic</b>			
Cation of weak base or small, highly charged metal cation	$\text{NH}_4\text{ClO}_2$ , $\text{NH}_4\text{CN}$ , $\text{Pb}(\text{CH}_3\text{COO})_2$	Cation <i>and</i> anion: $\text{NH}_4^+ + \text{H}_2\text{O} \rightleftharpoons \text{NH}_3 + \text{H}_3\text{O}^+$ $\text{ClO}_2^- + \text{H}_2\text{O} \rightleftharpoons \text{HClO}_2 + \text{OH}^-$	$<7.0$ if $K_{a(\text{cation})} > K_{b(\text{anion})}$ $>7.0$ if $K_{b(\text{anion})} > K_{a(\text{cation})}$
Anion of weak acid			
Cation of strong base	$\text{NaH}_2\text{PO}_4$ , $\text{KHCO}_3$ , $\text{NaHSO}_3$	Anion: $\text{HSO}_3^- + \text{H}_2\text{O} \rightleftharpoons \text{SO}_3^{2-} + \text{H}_3\text{O}^+$ $\text{HSO}_3^- + \text{H}_2\text{O} \rightleftharpoons \text{H}_2\text{SO}_3 + \text{OH}^-$	$<7.0$ if $K_{a(\text{anion})} > K_{b(\text{anion})}$ $>7.0$ if $K_{b(\text{anion})} > K_{a(\text{anion})}$
Anion of polyprotic acid			

## SAMPLE PROBLEM 18.14

Predicting the Relative Acidity of a Salt Solution from  $K_a$  and  $K_b$  of the Ions

**Problem** Determine whether aqueous solutions of the following salts are acidic, basic, or neutral at 25°C:

(a) zinc formate,  $Zn(HCOO)_2$  (b) potassium hydrogen sulfite,  $KHSO_3$

**Plan** (a) The formula consists of the small, highly charged, and therefore weakly acidic,  $Zn^{2+}$  cation and the weakly basic  $HCOO^-$  anion of the weak acid  $HCOOH$ . To determine the relative acidity of the solution, we write equations that show the reactions of the ions with water, and then find  $K_a$  of  $Zn^{2+}$  (in Appendix C) and calculate  $K_b$  of  $HCOO^-$  (from  $K_a$  of  $HCOOH$  in Appendix C) to see which ion reacts with water to a greater extent.

(b)  $K^+$  is from the strong base  $KOH$  and does not react with water; the anion,  $HSO_3^-$ , is the first anion of the weak polyprotic acid  $H_2SO_3$ . We write the reactions of this anion acting as a weak acid and as a weak base in water; we find its  $K_a$  (in Appendix C) and calculate its  $K_b$  (from the  $K_a$  of its conjugate acid,  $H_2SO_3$ , in Appendix C) to determine if the ion is a stronger acid or a stronger base.

**Solution** (a) Writing the reactions with water:

Obtaining  $K_a$  and  $K_b$  of the ions: From Appendix C, the  $K_a$  of  $Zn(H_2O)_6^{2+}(aq)$  is  $1 \times 10^{-9}$ . We obtain  $K_a$  of  $HCOOH$  and solve for  $K_b$  of  $HCOO^-$ :

$$K_b \text{ of } HCOO^- = \frac{K_w}{K_a \text{ of } HCOOH} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-4}} = 5.6 \times 10^{-11}$$

$K_a$  of  $Zn(H_2O)_6^{2+} > K_b$  of  $HCOO^-$ , so the solution is **acidic**.

(b) Writing the reactions with water:

Obtaining  $K_a$  and  $K_b$  of  $HSO_3^-$ : From Appendix C,  $K_a$  is  $6.5 \times 10^{-8}$ . We obtain  $K_a$  of  $H_2SO_3$  and solve for  $K_b$  of  $HSO_3^-$ :

$$K_b \text{ of } HSO_3^- = \frac{K_w}{K_a \text{ of } H_2SO_3} = \frac{1.0 \times 10^{-14}}{1.4 \times 10^{-2}} = 7.1 \times 10^{-13}$$

$K_a > K_b$ , so the solution is **acidic**.

## FOLLOW-UP PROBLEMS

**18.14A** Determine whether solutions of the following salts are acidic, basic, or neutral at 25°C: (a)  $Cu(CH_3COO)_2$ ; (b)  $NH_4F$ ; (c)  $KHC_6H_6O_6$ .

**18.14B** Determine whether solutions of the following salts are acidic, basic, or neutral at 25°C: (a)  $NaHCO_3$ ; (b)  $C_6H_5NH_3NO_2$ ; (c)  $NaH_2PO_4$ .

**SOME SIMILAR PROBLEMS** 18.121(b), 18.121(c), 18.123(c), 18.125(a), 18.125(b), 18.126(a), 18.127(a), and 18.127(b)

## Summary of Section 18.7

- › Salts that yield a neutral solution consist of ions that do not react with water.
- › Salts that yield an acidic solution contain an unreactive anion (from a strong acid) and a cation that releases a proton to water.
- › Salts that yield a basic solution contain an unreactive cation (from a strong base) and an anion that accepts a proton from water.
- › If both cation and anion react with water, the ion that reacts to the greater extent (higher  $K$ ) determines the acidity or basicity of the salt solution.
- › If the anion is amphiprotic (from a polyprotic acid), the strength of the anion as an acid ( $K_a$ ) or as a base ( $K_b$ ) determines the acidity of the salt solution.

## 18.8 GENERALIZING THE BRØNSTED-LOWRY CONCEPT: THE LEVELING EFFECT

In general, in solution, *an acid yields the cation and a base yields the anion that would be produced by autoionization of the solvent*. For example, in  $\text{H}_2\text{O}$ , all Brønsted-Lowry acids yield  $\text{H}_3\text{O}^+$  and all Brønsted-Lowry bases yield  $\text{OH}^-$ , which are the ions that form when water autoionizes.

This information lets us examine a key question: Why are all strong acids and strong bases *equally* strong in water? The answer is that *in water, the strongest acid possible is  $\text{H}_3\text{O}^+$  and the strongest base possible is  $\text{OH}^-$* :

- *For strong acids.* The moment we put gaseous HCl in water, it reacts with the base  $\text{H}_2\text{O}$  to form  $\text{H}_3\text{O}^+$ . The same holds for any strong acid because it dissociates *completely* to form  $\text{H}_3\text{O}^+$ . Thus, we are actually observing the acid strength of  $\text{H}_3\text{O}^+$ .
- *For strong bases.* A strong base, such as  $\text{Ba}(\text{OH})_2$ , dissociates completely in water to yield  $\text{OH}^-$ . Even strong bases that do not contain hydroxide ions in the solid, such as  $\text{K}_2\text{O}$ , do so. The oxide ion, which is a stronger base than  $\text{OH}^-$ , immediately takes a proton from water to form  $\text{OH}^-$ :

Thus, water exerts a **leveling effect** on any strong acid or base by reacting with it to form the products of water's autoionization. Acting as a base, water levels the strength of all strong acids by making them appear equally strong, and acting as an acid, it levels the strength of all strong bases.

Therefore, to rank the relative strengths of strong acids, we must dissolve them in a solvent that is a *weaker* base than water, so it accepts their protons less readily. For example, the hydrohalic acids increase in strength as the halogen becomes larger, as a result of the longer, weaker H—X bond (see Figure 18.9). But, in water, HF is weak, and HCl, HBr, and HI appear equally strong because they dissociate completely. When we dissolve them in pure acetic acid, however, *the acetic acid acts as the base* and accepts a proton:

[The use of “(acet)” instead of “(aq)” indicates solvation by  $\text{CH}_3\text{COOH}$ .] Because acetic acid is a *weaker base* than water, the three acids donate their protons to *different* extents. Measurements show that HI protonates the solvent to a greater extent than HBr, and HBr does so more than HCl; that is, in pure acetic acid,  $K_{\text{HI}} > K_{\text{HBr}} > K_{\text{HCl}}$ . Similarly, the relative strengths of strong bases are determined in a solvent that is a weaker acid than  $\text{H}_2\text{O}$ , such as pure liquid  $\text{NH}_3$ .

### › Summary of Section 18.8

- › Strong acids (or strong bases) dissociate completely to yield  $\text{H}_3\text{O}^+$  (or  $\text{OH}^-$ ) in water; in effect, water equalizes (levels) their strengths.
- › Strong acids show differences in strength when dissolved in a weaker base than water, such as acetic acid.

## 18.9 ELECTRON-PAIR DONATION AND THE LEWIS ACID-BASE DEFINITION

The final acid-base concept we consider was developed by Gilbert N. Lewis, whose contribution to understanding valence electron pairs in bonding we discussed in Chapter 9. Whereas the Brønsted-Lowry concept focuses on the proton in defining a

species as an acid or a base, the Lewis concept highlights the role of the *electron pair*. The **Lewis acid-base definition** holds that

- A *base* is any species that *donates* an electron pair to form a bond.
- An *acid* is any species that *accepts* an electron pair to form a bond.

The Lewis definition, like the Brønsted-Lowry definition, requires that a base have an electron pair to donate, so it does not expand the classes of bases. However, *it greatly expands the classes of acids*. Many species, such as  $\text{CO}_2$  and  $\text{Cu}^{2+}$ , that do not contain H in their formula (and thus cannot be Brønsted-Lowry acids) are Lewis acids because they accept an electron pair in reactions. In fact, the proton itself is a Lewis acid because it accepts the electron pair donated by a base:

Thus, all Brønsted-Lowry acids donate  $\text{H}^+$ , a Lewis acid.

The product of a Lewis acid-base reaction is an **adduct**, a single species that contains a *new covalent bond*:

Thus, the Lewis concept radically broadens the idea of an acid-base reaction:

- To Arrhenius, it is the formation of  $\text{H}_2\text{O}$  from  $\text{H}^+$  and  $\text{OH}^-$ .
- To Brønsted and Lowry, it is  $\text{H}^+$  transfer from a stronger acid to a stronger base to form a weaker base and weaker acid.
- To Lewis, it is *the donation and acceptance of an electron pair to form a covalent bond in an adduct*.

By definition, then,

- A Lewis base must have a lone pair of electrons to donate.
- A Lewis acid must have a vacant orbital (or the ability to rearrange its bonds to form one) to accept a lone electron pair and form a new bond.

In this section, we discuss molecules and positive metal ions that act as Lewis acids.

## Molecules as Lewis Acids

Many molecules act as Lewis acids. In every case, the atom accepting the electron pair has *low electron density* due to either an electron deficiency or a polar multiple bond.

**Lewis Acids with Electron-Deficient Atoms** The most important of the *electron-deficient* Lewis acids are compounds of the Group 3A(13) elements boron and aluminum. Recall from Chapters 10 and 14 that these compounds have fewer than eight electrons around the central atom, so they react to complete that atom's octet. For example, boron trifluoride accepts an electron pair from ammonia to form a covalent bond:

Aluminum chloride, a salt, dissolves freely in relatively nonpolar diethyl ether when the ether's O atom donates an electron pair to Al to form a covalent bond:

This acidic behavior of boron and aluminum halides is often used in organic syntheses. For example, a methyl group is added to the benzene ring by the action of  $\text{CH}_3\text{Cl}$

in the presence of  $\text{AlCl}_3$ . The Lewis acid  $\text{AlCl}_3$  abstracts the Lewis base  $\text{Cl}^-$  from  $\text{CH}_3\text{Cl}$  to form an ionic adduct that has a reactive  $\text{CH}_3^+$  group, which then attacks the electron-rich benzene ring:

**Lewis Acids with Polar Multiple Bonds** Molecules with a polar double bond also function as Lewis acids. An electron pair on the Lewis base approaches the partially positive end of the double bond to form the new bond in the adduct, as the  $\pi$  bond breaks. For example, consider the reaction of  $\text{SO}_2$  in water. The electronegative O atoms in  $\text{SO}_2$  make the central S partially positive. The O atom of water donates a lone pair to the S, thus forming an S—O bond and breaking one of the  $\pi$  bonds. Then, a proton is transferred from water to the O that was part of the  $\pi$  bond. The resulting adduct is sulfurous acid:

The analogous formation of a carbonate from a metal oxide and carbon dioxide occurs in a nonaqueous system. The  $\text{O}^{2-}$  ion (shown coming from  $\text{CaO}$ ) donates an electron pair to the partially positive C in  $\text{CO}_2$ , a  $\pi$  bond breaks, and the  $\text{CO}_3^{2-}$  ion (shown as part of  $\text{CaCO}_3$ ) is the adduct:

## Metal Cations as Lewis Acids

In the Lewis sense, hydration of a metal ion is itself an acid-base reaction. When electron pairs on the O atoms of  $\text{H}_2\text{O}$  molecules form covalent bonds, the hydrated cation is the adduct; thus, *a metal ion acts as a Lewis acid when it dissolves in water*:

Ammonia is a stronger Lewis base than water because, when it is added to the aqueous solution of the hydrated cation, it displaces  $\text{H}_2\text{O}$ , with  $K \gg 1$ :

We discuss the equilibrium nature of these acid-base reactions in greater detail in Chapter 19, and we investigate the structures of these ions in Chapter 23.

Many biomolecules with central metal ions are Lewis adducts. Most often, O and N atoms of organic groups donate their lone pairs as the Lewis bases. Chlorophyll is a Lewis adduct of a central  $\text{Mg}^{2+}$  and the four N atoms of a tetrapyrrole (porphin) ring system (Figure 18.13). Vitamin  $\text{B}_{12}$  has a similar structure with a central  $\text{Co}^{3+}$ , and so does heme with a central  $\text{Fe}^{2+}$ . Several other metal ions, such as  $\text{Zn}^{2+}$ ,  $\text{Mo}^{2+}$ , and  $\text{Cu}^{2+}$ , are bound at the active sites of enzymes and function as Lewis acids in the catalytic process (see the Chemical Connections at the end of Section 23.4).

**Figure 18.13** The  $\text{Mg}^{2+}$  ion as a Lewis acid in chlorophyll.

## SAMPLE PROBLEM 18.15

## Identifying Lewis Acids and Bases

**Problem** Identify the Lewis acids and Lewis bases in the following reactions:

**Plan** We examine the formulas to see which species accepts the electron pair (Lewis acid) and which donates it (Lewis base) in forming the adduct. The Lewis base must have a lone pair of electrons.

**Solution** (a) The  $\text{H}^+$  ion accepts an electron pair from the  $\text{OH}^-$  ion in forming a bond.  $\text{H}^+$  is the Lewis acid and  $\text{OH}^-$  is the Lewis base.

(b) The  $\text{Cl}^-$  ion has four lone pairs and uses one to form a new bond to the central B.  $\text{BCl}_3$  is the Lewis acid and  $\text{Cl}^-$  is the Lewis base.

(c) The  $\text{K}^+$  ion does not have any valence electrons to provide, so the bond is formed when electron pairs from O atoms of water enter empty orbitals on  $\text{K}^+$ .  $\text{K}^+$  is the Lewis acid and  $\text{H}_2\text{O}$  is the Lewis base.

**Check** The Lewis acids ( $\text{H}^+$ ,  $\text{BCl}_3$ , and  $\text{K}^+$ ) each have an unfilled valence shell that can accept an electron pair from the Lewis base ( $\text{OH}^-$ ,  $\text{Cl}^-$ , or  $\text{H}_2\text{O}$ ).

## FOLLOW-UP PROBLEMS

**18.15A** Identify the Lewis acids and Lewis bases:

**18.15B** Identify the Lewis acids and Lewis bases:

**SOME SIMILAR PROBLEMS** 18.142 and 18.143

## An Overview of Acid-Base Definitions

From a broader chemical perspective, the diversity of acid-base reactions takes on more unity. Chemists see a common theme in reactions as diverse as a standardized base being used to analyze an unknown fatty acid, baking soda being used in bread-making, and even oxygen binding to hemoglobin in a blood cell. Let's see how the three acid-base definitions fit together.

1. The *Arrhenius definition*, which was the first attempt at describing acids and bases on the molecular level, is the most limited and narrow of the three. It applies only to species with an H atom or an OH group that is released as an ion when the species dissolves in water. Because relatively few species have these structural prerequisites, Arrhenius acid-base reactions are relatively few in number, and all occur in  $\text{H}_2\text{O}$  and result in the formation of  $\text{H}_2\text{O}$ .

2. The *Brønsted-Lowry definition* sees acid-base reactions as proton-transfer processes that need not occur in water. A Brønsted-Lowry acid, like an Arrhenius acid, must have an H, but a Brønsted-Lowry base is any species with an electron pair available to accept a proton. This definition includes many more species as bases, including  $\text{OH}^-$ . It defines the acid-base reaction in terms of conjugate acid-base pairs, with an acid and a base on both sides of the reaction. The system reaches equilibrium based on the relative strengths of the acid, the base, and their conjugates.

3. The *Lewis definition* has the widest scope and includes the other two. The defining event of a Lewis acid-base reaction is the donation and acceptance of an electron pair to form a new covalent bond in an adduct. Lewis bases still must have an electron pair to donate, but Lewis acids—the electron-pair acceptors—include many species not encompassed by the other definitions, including molecules with electron-deficient atoms or with polar double bonds, metal ions, and even  $\text{H}^+$  itself.

## › Summary of Section 18.9

- › The Lewis acid-base definition focuses on the donation or acceptance of an electron pair to form a new covalent bond in an adduct, the product of an acid-base reaction. Lewis bases donate the electron pair, and Lewis acids accept it.
- › Thus, many species that do not contain H are Lewis acids. Molecules with polar double bonds act as Lewis acids, as do those with electron-deficient atoms.
- › Metal ions act as Lewis acids when they dissolve in water, which acts as a Lewis base, to form a hydrated cation as the adduct.
- › Many metal ions function as Lewis acids in biomolecules.

## CHAPTER REVIEW GUIDE

### Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

#### Understand These Concepts

1. Why the proton is bonded to a water molecule, as  $\text{H}_3\text{O}^+$ , in all aqueous acid-base systems (§18.1)
2. The Arrhenius definitions of an acid and a base (§18.1)
3. Why all reactions of a strong acid and a strong base have the same  $\Delta H_{\text{rxn}}^\circ$  (§18.1)
4. How the strength of an acid (or base) relates to the extent of its dissociation into ions in water (§18.1)
5. How relative acid strength is expressed by the acid-dissociation constant  $K_a$  (§18.1)
6. How the autoionization of water is expressed by  $K_w$  (§18.2)
7. Why  $[\text{H}_3\text{O}^+]$  is inversely related to  $[\text{OH}^-]$  in any aqueous solution (§18.2)
8. How the relative magnitudes of  $[\text{H}_3\text{O}^+]$  and  $[\text{OH}^-]$  define whether a solution is acidic, basic, or neutral (§18.2)
9. The Brønsted-Lowry definitions of an acid and a base and how an acid-base reaction can be viewed as a proton-transfer process (§18.3)
10. How water acts as a base (or as an acid) when an acid (or a base) dissolves in it (§18.3)
11. How a conjugate acid-base pair differs by one proton (§18.3)
12. How a Brønsted-Lowry acid-base reaction involves two conjugate acid-base pairs (§18.3)
13. Why a stronger acid and base react ( $K_c > 1$ ) to form a weaker base and acid (§18.3)
14. How the percent dissociation of a weak acid increases as its concentration decreases (§18.4)
15. How a polyprotic acid dissociates in two or more steps and why only the first step supplies significant  $[\text{H}_3\text{O}^+]$  (§18.4)
16. The effects of electronegativity, bond polarity, and bond strength on acid strength (§18.5)
17. Why aqueous solutions of small, highly charged metal ions are acidic (§18.5)
18. How weak bases in water accept a proton rather than dissociate; the meaning of  $K_b$  and  $\text{p}K_b$  (§18.6)
19. How ammonia, amines, and weak-acid anions act as weak bases in water (§18.6)
20. Why relative concentrations of HA and  $\text{A}^-$  determine the acidity or basicity of their solutions (§18.6)

21. The relationship of the  $K_a$  and  $K_b$  of a conjugate acid-base pair to  $K_w$  (§18.6)
22. The various combinations of cations and anions that lead to acidic, basic, or neutral salt solutions (§18.7)
23. Why the strengths of strong acids are leveled in water but differ in a less basic solvent (§18.8)
24. The Lewis definitions of an acid and a base and how a Lewis acid-base reaction involves the donation and acceptance of an electron pair to form a covalent bond (§18.9)
25. How molecules with electron-deficient atoms, molecules with polar multiple bonds, and metal cations act as Lewis acids (§18.9)

#### Master These Skills

1. Classifying strong and weak acids and bases from their formulas (SP 18.1)
2. Using  $K_w$  to calculate  $[\text{H}_3\text{O}^+]$  or  $[\text{OH}^-]$  in an aqueous solution (SP 18.2)
3. Using p-scales to express  $[\text{H}_3\text{O}^+]$ ,  $[\text{OH}^-]$ , and  $K$  (§18.2)
4. Calculating  $[\text{H}_3\text{O}^+]$ , pH,  $[\text{OH}^-]$ , and pOH (SP 18.3)
5. Identifying conjugate acid-base pairs (SP 18.4)
6. Using relative acid strengths to predict the net direction of an acid-base reaction (SPs 18.5, 18.6)
7. Calculating  $K_a$  of a weak acid from pH (SP 18.7)
8. Calculating  $[\text{H}_3\text{O}^+]$  (and, thus, pH) from  $K_a$  and  $[\text{HA}]_{\text{init}}$  (SP 18.8)
9. Applying the quadratic equation to find a concentration (Follow-Up Problem 18.8A)
10. Calculating the percent dissociation of a weak acid (§18.4 and SP 18.9)
11. Calculating  $[\text{H}_3\text{O}^+]$  and other concentrations for a polyprotic acid (SP 18.10)
12. Predicting relative acid strengths of nonmetal hydrides and oxoacids (§18.5)
13. Calculating pH from  $K_b$  and  $[\text{B}]_{\text{init}}$  (SP 18.11)
14. Finding  $K_b$  of  $\text{A}^-$  from  $K_a$  of HA and  $K_w$  (§18.6 and SP 18.12)
15. Calculating pH from  $K_b$  of  $\text{A}^-$  and  $[\text{A}^-]_{\text{init}}$  (SP 18.12)
16. Predicting the relative acidity of a salt solution from the nature of the cation and anion (SPs 18.13, 18.14)
17. Identifying Lewis acids and bases (SP 18.15)

## Key Terms

Page numbers appear in parentheses.

acid-base indicator (803)	autoionization (798)	hydronium ion, $\text{H}_3\text{O}^+$ (794)	neutralization (794)
acid-dissociation (acid-ionization) constant ( $K_a$ ) (796)	base-dissociation (base-ionization) constant ( $K_b$ ) (818)	ion-product constant for water ( $K_w$ ) (799)	pH (800)
adduct (828)	Brønsted-Lowry acid-base definition (803)	leveling effect (827)	polyprotic acid (813)
Arrhenius acid-base definition (794)	conjugate acid-base pair (804)	Lewis acid-base definition (828)	proton acceptor (803)
			proton donor (803)

## Key Equations and Relationships

Page numbers appear in parentheses.

**18.1** Defining the acid-dissociation constant (796):

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$$

**18.2** Defining the ion-product constant for water (799):

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14} \text{ (at } 25^\circ\text{C)}$$

**18.3** Defining pH (800):

$$\text{pH} = -\log [\text{H}_3\text{O}^+]$$

**18.4** Relating  $\text{p}K_w$  to pH and pOH (801):

$$\text{p}K_w = \text{pH} + \text{pOH} = 14.00 \text{ (at } 25^\circ\text{C)}$$

**18.5** Finding the percent dissociation of HA (812):

$$\text{Percent HA dissociated} = \frac{[\text{HA}]_{\text{dissoc}}}{[\text{HA}]_{\text{init}}} \times 100$$

**18.6** Defining the base-dissociation constant (818):

$$K_b = \frac{[\text{BH}^+][\text{OH}^-]}{[\text{B}]}$$

**18.7** Expressing the relationship among  $K_a$ ,  $K_b$ , and  $K_w$  (821):

$$K_a \times K_b = K_w$$

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

**18.1A** (a)  $\text{HClO}_3$ ; number of O atoms exceeds number of H atoms by two.

(b) HCl; one of the strong hydrohalic acids.

(c) NaOH; one of the Group 1A(1) hydroxides.

**18.1B** (a) Weak base; this is an amine with a lone electron pair on the N.

(b) Strong acid; one of the strong hydrohalic acids.

(c) Weak acid; number of O atoms equals the number of H atoms.

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{BrO}^-]}{[\text{HBrO}]}$$

(d) Strong base; Group 2A(2) metal hydroxide with Ca as the metal.

$$\text{18.2A } [\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{6.7 \times 10^{-2}} = 1.5 \times 10^{-13} \text{ M; basic}$$

$$\text{18.2B } [\text{OH}^-] = \frac{K_w}{[\text{H}_3\text{O}^+]} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-10}} = 5.6 \times 10^{-5} \text{ M; basic}$$

**18.3A**  $\text{pH} = 14.00 - \text{pOH} = 14.00 - 4.48 = 9.52$ 

$$[\text{OH}^-] = 10^{-\text{pOH}} = 10^{-4.48} = 3.3 \times 10^{-5} \text{ M}$$

$$[\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{3.3 \times 10^{-5}} = 3.0 \times 10^{-10} \text{ M}$$

**18.3B**  $\text{pOH} = 14.00 - \text{pH} = 14.00 - 2.28 = 11.72$ 

$$[\text{H}_3\text{O}^+] = 10^{-\text{pH}} = 10^{-2.28} = 5.2 \times 10^{-3} \text{ M}$$

$$[\text{OH}^-] = \frac{K_w}{[\text{H}_3\text{O}^+]} = \frac{1.0 \times 10^{-14}}{5.2 \times 10^{-3}} = 1.9 \times 10^{-12} \text{ M}$$

**18.4A** (a)  $\text{CH}_3\text{COOH}/\text{CH}_3\text{COO}^-$  and  $\text{H}_3\text{O}^+/\text{H}_2\text{O}$ (b)  $\text{H}_2\text{O}/\text{OH}^-$  and  $\text{HF}/\text{F}^-$ **18.4B** (a)  $\text{H}_2\text{SO}_3$  (b)  $\text{C}_5\text{H}_5\text{N}$  (c)  $\text{HCO}_3^-$  (d)  $\text{CN}^-$ **18.5A** (a)  $\text{H}_2\text{SO}_3(aq) + \text{CO}_3^{2-}(aq) \rightleftharpoons \text{HSO}_3^-(aq) + \text{HCO}_3^-(aq)$   
stronger acid + stronger base  $\rightarrow$  weaker base + weaker acid**18.5B** (a)  $\text{NH}_3(g) + \text{H}_2\text{O}(l) \rightleftharpoons \text{NH}_4^+(aq) + \text{OH}^-(aq)$ (b)  $\text{NH}_3(g) + \text{H}_3\text{O}^+(aq; \text{from HCl}) \rightarrow \text{NH}_4^+(aq) + \text{H}_2\text{O}(l)$ (c)  $\text{NH}_4^+(aq) + \text{OH}^-(aq; \text{from NaOH}) \rightarrow \text{NH}_3(g) + \text{H}_2\text{O}(l)$ **18.6A** There are more HB molecules than HA, so  $K_c > 1$  and HA is the stronger acid.**18.6B** Since HD is the stronger acid, there should be more  $\text{D}^-$  particles than  $\text{C}^-$  particles: thus,  $\text{D}^-$  is black (5 particles) and  $\text{C}^-$  is green (3 particles).**18.7A**  $\text{NH}_4^+(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{NH}_3(aq) + \text{H}_3\text{O}^+(aq)$ 

$$[\text{H}_3\text{O}^+] = 10^{-\text{pH}} = 10^{-5.0} = 1 \times 10^{-5} \text{ M} = [\text{NH}_3]$$

And,  $[\text{NH}_4^+] = 0.2 \text{ M} - (1 \times 10^{-5} \text{ M}) \approx 0.2 \text{ M}$ 

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{NH}_3]}{[\text{NH}_4^+]} \approx \frac{(1 \times 10^{-5})^2}{0.2} = 5 \times 10^{-10}$$

**18.7B**  $\text{CH}_2\text{CHCOOH}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{CH}_2\text{CHCOO}^-(aq) + \text{H}_3\text{O}^+(aq)$ 

$$[\text{H}_3\text{O}^+] = 10^{-\text{pH}} = 10^{-2.43} = 0.0037 \text{ M} = [\text{CH}_2\text{CHCOO}^-]$$

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{CH}_2\text{CHCOO}^-]}{[\text{CH}_2\text{CHCOOH}]} \approx \frac{(0.0037)^2}{0.30} = 4.6 \times 10^{-5}$$

$$\text{18.8A } \frac{[\text{HOCN}]_{\text{init}}}{K_a} = \frac{0.10}{3.5 \times 10^{-4}} = 286 < 400$$

You must solve a quadratic equation:

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{OCN}^-]}{[\text{HOCN}]} = 3.5 \times 10^{-4} = \frac{(x)(x)}{0.10 - x}$$

$$x^2 + (3.5 \times 10^{-4})x - (3.5 \times 10^{-5}) = 0$$

$$x = [\text{H}_3\text{O}^+] = 5.7 \times 10^{-3} \text{ M}$$

$$\text{pH} = -\log(5.7 \times 10^{-3}) = 2.24$$

$$18.8B \quad K_a = 10^{-pK_a} = 10^{-4.20} = 6.3 \times 10^{-5}$$

$$\frac{[\text{C}_6\text{H}_5\text{COOH}]_{\text{init}}}{K_a} = \frac{0.25}{6.3 \times 10^{-5}} = 3968 > 400$$

You may assume that  $0.25 - x = 0.25 \text{ M}$ :

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{C}_6\text{H}_5\text{COO}^-]}{[\text{C}_6\text{H}_5\text{COOH}]} = 6.3 \times 10^{-5} = \frac{(x)(x)}{0.25 - x} \approx \frac{x^2}{0.25}$$

$$x = [\text{H}_3\text{O}^+] = 4.0 \times 10^{-3} \text{ M}$$

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log [4.0 \times 10^{-3}] = 2.40$$

$$18.9A \quad \frac{[\text{HCN}]_{\text{init}}}{K_a} = \frac{0.75}{6.2 \times 10^{-10}} = 1.2 \times 10^9 > 400$$

You may assume that  $0.75 - x = 0.75$ :

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{CN}^-]}{[\text{HCN}]} = 6.2 \times 10^{-10} = \frac{(x)(x)}{0.75 - x} \approx \frac{x^2}{0.75}$$

$$x = 2.2 \times 10^{-5} \text{ M} = [\text{HCN}]_{\text{dissoc}}$$

$$\text{Percent dissociation} = \frac{[\text{HCN}]_{\text{dissoc}}}{[\text{HCN}]_{\text{init}}} \times 100 = \frac{2.2 \times 10^{-5}}{0.75} \times 100 = 0.0029\%$$

$$18.9B \quad 3.16\% = \frac{[\text{HA}]_{\text{dissoc}}}{[\text{HA}]_{\text{init}}} \times 100 = \frac{x}{1.5} \times 100$$

$$x = 0.047 \text{ M} = [\text{HA}]_{\text{dissoc}} = [\text{H}_3\text{O}^+] = [\text{A}^-]$$

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} = \frac{(0.047)(0.047)}{1.5 - 0.047} = 1.5 \times 10^{-3}$$

$$18.10A \quad \frac{[\text{H}_2\text{C}_2\text{O}_4]_{\text{init}}}{K_{a1}} = \frac{0.150}{5.6 \times 10^{-2}} = 2.7 < 400$$

You must solve a quadratic equation:

$$K_{a1} = \frac{[\text{H}_3\text{O}^+][\text{HC}_2\text{O}_4^-]}{[\text{H}_2\text{C}_2\text{O}_4]} = 5.6 \times 10^{-2} = \frac{(x)(x)}{0.150 - x}$$

$$x^2 + (5.6 \times 10^{-2})x - (8.4 \times 10^{-3}) = 0$$

$$x = [\text{H}_3\text{O}^+] = 0.068 \text{ M}; \text{pH} = -\log (0.068) = 1.17$$

$$x = [\text{HC}_2\text{O}_4^-] = 0.068 \text{ M}; [\text{H}_2\text{C}_2\text{O}_4] = 0.150 \text{ M} - x = 0.082 \text{ M}$$

$$K_{a2} = \frac{[\text{H}_3\text{O}^+][\text{C}_2\text{O}_4^{2-}]}{[\text{HC}_2\text{O}_4^-]}$$

$$[\text{C}_2\text{O}_4^{2-}] = \frac{K_{a2}[\text{HC}_2\text{O}_4^-]}{[\text{H}_3\text{O}^+]} = \frac{(5.4 \times 10^{-5})(0.068)}{0.068} = 5.4 \times 10^{-5} \text{ M}$$

$$18.10B \quad \frac{[\text{H}_2\text{CO}_3]_{\text{init}}}{K_{a1}} = \frac{0.075}{4.5 \times 10^{-7}} = 1.7 \times 10^5 > 400$$

You may assume that  $0.075 - x = 0.075 \text{ M}$ :

$$K_{a1} = \frac{[\text{H}_3\text{O}^+][\text{HCO}_3^-]}{[\text{H}_2\text{CO}_3]} = 4.5 \times 10^{-7} = \frac{(x)(x)}{0.075 - x} \approx \frac{x^2}{0.075}$$

$$x = [\text{H}_3\text{O}^+] = 1.8 \times 10^{-4} \text{ M}; \text{pH} = 3.74$$

$$x = [\text{HCO}_3^-] = 1.8 \times 10^{-4} \text{ M}; [\text{H}_2\text{CO}_3] = 0.075 \text{ M} - x = 0.075 \text{ M}$$

$$K_{a2} = \frac{[\text{H}_3\text{O}^+][\text{CO}_3^{2-}]}{[\text{HCO}_3^-]}$$

$$[\text{CO}_3^{2-}] = \frac{K_{a2}[\text{HCO}_3^-]}{[\text{H}_3\text{O}^+]} = \frac{(4.7 \times 10^{-11})(1.8 \times 10^{-4})}{1.8 \times 10^{-4}} = 4.7 \times 10^{-11} \text{ M}$$

$$18.11A \quad K_b = 10^{-pK_b} = 10^{-8.77} = 1.7 \times 10^{-9}$$

$$\frac{[\text{C}_5\text{H}_5\text{N}]_{\text{init}}}{K_b} = \frac{0.10}{1.7 \times 10^{-9}} = 5.9 \times 10^7 > 400$$

You may assume that  $0.10 - x = 0.10 \text{ M}$ :

$$K_b = \frac{[\text{C}_5\text{H}_5\text{NH}^+][\text{OH}^-]}{[\text{C}_5\text{H}_5\text{N}]} = 1.7 \times 10^{-9} = \frac{(x)(x)}{0.10 - x} \approx \frac{x^2}{0.10}$$

$$x = [\text{OH}^-] = 1.3 \times 10^{-5} \text{ M};$$

$$[\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{1.3 \times 10^{-5}} = 7.7 \times 10^{-10} \text{ M}$$

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log (7.7 \times 10^{-10}) = 9.11$$

$$18.11B \quad \frac{[\text{C}_6\text{H}_5\text{CH}_2\text{CH}(\text{CH}_3)\text{NH}_2]_{\text{init}}}{K_b} = \frac{0.075}{6.3 \times 10^{-5}} = 1200 > 400$$

You may assume that  $0.075 - x = 0.075 \text{ M}$ :

$$K_b = \frac{[\text{C}_6\text{H}_5\text{CH}_2\text{CH}(\text{CH}_3)\text{NH}_3^+][\text{OH}^-]}{[\text{C}_6\text{H}_5\text{CH}_2\text{CH}(\text{CH}_3)\text{NH}_2]} = 6.3 \times 10^{-5}$$

$$= \frac{(x)(x)}{0.075 - x} \approx \frac{x^2}{0.075}$$

$$x = [\text{OH}^-] = 2.2 \times 10^{-3} \text{ M};$$

$$[\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{2.2 \times 10^{-3}} = 4.5 \times 10^{-12} \text{ M}$$

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log (4.5 \times 10^{-12}) = 11.35$$

$$18.12A \quad K_b \text{ of } \text{ClO}^- = \frac{K_w}{K_a \text{ of HClO}} = \frac{1.0 \times 10^{-14}}{2.9 \times 10^{-8}} = 3.4 \times 10^{-7}$$

Assuming  $0.20 \text{ M} - x \approx 0.20 \text{ M}$ ,

$$K_b = \frac{[\text{HClO}][\text{OH}^-]}{[\text{ClO}^-]} = 3.4 \times 10^{-7} = \frac{(x)(x)}{0.20 - x} \approx \frac{x^2}{0.20}$$

$$x = [\text{OH}^-] = 2.6 \times 10^{-4} \text{ M}; [\text{H}_3\text{O}^+] = 3.8 \times 10^{-11} \text{ M}; \text{pH} = 10.42$$

$$18.12B \quad K_b \text{ of } \text{NO}_2^- = \frac{K_w}{K_a \text{ of HNO}_2} = \frac{1.0 \times 10^{-14}}{7.1 \times 10^{-4}} = 1.4 \times 10^{-11}$$

Assuming  $0.80 \text{ M} - x \approx 0.80 \text{ M}$ ,

$$K_b = \frac{[\text{HNO}_2][\text{OH}^-]}{[\text{NO}_2^-]} = 1.4 \times 10^{-11} = \frac{(x)(x)}{0.80 - x} \approx \frac{x^2}{0.80}$$

$$x = [\text{OH}^-] = 3.3 \times 10^{-6} \text{ M}; [\text{H}_3\text{O}^+] = 3.0 \times 10^{-9} \text{ M}; \text{pH} = 8.52$$

18.13A (a) Basic:  $\text{K}^+$  is from the strong base KOH, so it does not react with water;  $\text{ClO}_2^-$  is the anion of the weak acid HClO<sub>2</sub> and reacts with water to produce  $\text{OH}^-$ :

(b) Acidic:  $\text{NO}_3^-$  is from the strong acid HNO<sub>3</sub>, so it does not react with water;  $\text{CH}_3\text{NH}_3^+$  is the cation of the weak base CH<sub>3</sub>NH<sub>2</sub> and reacts with water to produce  $\text{H}_3\text{O}^+$ :

(c) Neutral:  $\text{Rb}^+$  is from the strong base RbOH;  $\text{Br}^-$  is from the strong acid HBr. Neither ion reacts with water.

18.13B (a) Acidic:  $\text{Br}^-$  is from the strong acid HBr, so it does not react with water; the small, highly charged  $\text{Fe}^{3+}$  ion forms  $\text{Fe}(\text{H}_2\text{O})_6^{3+}$ , which reacts with water to produce  $\text{H}_3\text{O}^+$ :

(b) Basic:  $\text{Ca}^{2+}$  is from the strong base Ca(OH)<sub>2</sub>, so it does not react with water;  $\text{NO}_2^-$  is the anion of the weak acid HNO<sub>2</sub> and reacts with water to produce  $\text{OH}^-$ :

(c) Acidic:  $\text{I}^-$  is from the strong acid HI, so it does not react with water;  $\text{C}_6\text{H}_5\text{NH}_3^+$  is the cation of the weak base C<sub>6</sub>H<sub>5</sub>NH<sub>2</sub> and reacts with water to produce  $\text{H}_3\text{O}^+$ :

18.14A (a) From Appendix C,  $K_a$  of Cu(H<sub>2</sub>O)<sub>6</sub><sup>2+</sup> =  $3 \times 10^{-8}$

$$K_b \text{ of } \text{CH}_3\text{COO}^- = \frac{K_w}{K_a \text{ of } \text{CH}_3\text{COOH}} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

Since  $K_a > K_b$ , Cu(CH<sub>3</sub>COO)<sub>2</sub>(aq) is acidic.

$$(b) K_a \text{ of } \text{NH}_4^+ = \frac{K_w}{K_b \text{ of } \text{NH}_3} = \frac{1.0 \times 10^{-14}}{1.76 \times 10^{-5}} = 5.7 \times 10^{-10}$$

$$K_b \text{ of } \text{F}^- = \frac{K_w}{K_a \text{ of } \text{HF}} = \frac{1.0 \times 10^{-14}}{6.8 \times 10^{-4}} = 1.5 \times 10^{-11}$$

Because  $K_a > K_b$ , NH<sub>4</sub>F(aq) is acidic.

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

(continued)

(c) From Appendix C,  $K_a$  of  $\text{HC}_6\text{H}_6\text{O}_6^- = 5 \times 10^{-12}$   

$$K_b \text{ of } \text{HC}_6\text{H}_6\text{O}_6^- = \frac{K_w}{K_a \text{ of } \text{H}_2\text{C}_6\text{H}_6\text{O}_6} = \frac{1.0 \times 10^{-14}}{1.0 \times 10^{-5}} = 1.0 \times 10^{-9}$$

Because  $K_b > K_a$ ,  $\text{KHC}_6\text{H}_6\text{O}_6(aq)$  is basic.

**18.14B** (a) From Appendix C,  $K_a$  of  $\text{HCO}_3^- = 4.7 \times 10^{-11}$   

$$K_b \text{ of } \text{HCO}_3^- = \frac{K_w}{K_a \text{ of } \text{H}_2\text{CO}_3} = \frac{1.0 \times 10^{-14}}{4.5 \times 10^{-7}} = 2.2 \times 10^{-8}$$

Because  $K_b > K_a$ ,  $\text{NaHCO}_3(aq)$  is basic.

(b)  $K_a$  of  $\text{C}_6\text{H}_5\text{NH}_3^+ = \frac{K_w}{K_b \text{ of } \text{C}_6\text{H}_5\text{NH}_2} = \frac{1.0 \times 10^{-14}}{4.0 \times 10^{-10}} = 2.5 \times 10^{-5}$

$K_b$  of  $\text{NO}_2^- = \frac{K_w}{K_a \text{ of } \text{HNO}_2} = \frac{1.0 \times 10^{-14}}{7.1 \times 10^{-4}} = 1.4 \times 10^{-11}$

Because  $K_a > K_b$ ,  $\text{C}_6\text{H}_5\text{NH}_3\text{NO}_2(aq)$  is acidic.(c) From Appendix C,  $K_a$  of  $\text{H}_2\text{PO}_4^- = 6.3 \times 10^{-8}$ 

$$K_b \text{ of } \text{H}_2\text{PO}_4^- = \frac{K_w}{K_a \text{ of } \text{H}_3\text{PO}_4} = \frac{1.0 \times 10^{-14}}{7.2 \times 10^{-3}} = 1.4 \times 10^{-12}$$

Because  $K_a > K_b$ ,  $\text{NaH}_2\text{PO}_4(aq)$  is acidic.**18.15A** (a)  $\text{OH}^-$  is the Lewis base;  $\text{Al}(\text{OH})_3$  is the Lewis acid.(b)  $\text{H}_2\text{O}$  is the Lewis base;  $\text{SO}_3$  is the Lewis acid.(c)  $\text{NH}_3$  is the Lewis base;  $\text{Co}^{3+}$  is the Lewis acid.**18.15B** (a)  $\text{H}_2\text{O}$  is the Lewis base;  $\text{B}(\text{OH})_3$  is the Lewis acid.(b)  $\text{I}^-$  is the Lewis base;  $\text{Cd}^{2+}$  is the Lewis acid.(c)  $\text{F}^-$  is the Lewis base;  $\text{SiF}_4$  is the Lewis acid.

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

**Note:** Unless stated otherwise, all problems refer to aqueous solutions at 298 K (25°C).

## Acids and Bases in Water

(Sample Problem 18.1)

## Concept Review Questions

**18.1** What is the role of water in the Arrhenius acid-base definition?

**18.2** What do Arrhenius acids have in common? What do Arrhenius bases have in common? Explain neutralization in terms of the Arrhenius acid-base definition. What data led Arrhenius to propose this idea of neutralization?

**18.3** Why is the Arrhenius acid-base definition too limited? Give an example for which the Arrhenius definition does not apply.

**18.4** What do “strong” and “weak” mean for acids and bases? The  $K_a$  values of weak acids vary over more than 10 orders of magnitude. What do the acids have in common that makes them “weak”?

## Skill-Building Exercises (grouped in similar pairs)

**18.5** Which of the following are Arrhenius acids?

(a)  $\text{H}_2\text{O}$  (b)  $\text{Ca}(\text{OH})_2$  (c)  $\text{H}_3\text{PO}_3$  (d)  $\text{HI}$ 

**18.6** Which of the following are Arrhenius acids?

(a)  $\text{NaHSO}_4$  (b)  $\text{CH}_4$  (c)  $\text{NaH}$  (d)  $\text{H}_3\text{N}$ 

**18.7** Which of the following are Arrhenius bases?

(a)  $\text{H}_3\text{AsO}_4$  (b)  $\text{Ba}(\text{OH})_2$  (c)  $\text{HClO}$  (d)  $\text{KOH}$ 

**18.8** Which of the following are Arrhenius bases?

(a)  $\text{CH}_3\text{COOH}$  (b)  $\text{HOH}$  (c)  $\text{CH}_3\text{OH}$  (d)  $\text{H}_2\text{NNH}_2$ 

**18.9** Write the  $K_a$  expression for each of the following in water:

(a)  $\text{HCN}$  (b)  $\text{HCO}_3^-$  (c)  $\text{HCOOH}$ 

**18.10** Write the  $K_a$  expression for each of the following in water:

(a)  $\text{CH}_3\text{NH}_3^+$  (b)  $\text{HClO}$  (c)  $\text{H}_2\text{S}$ 

**18.11** Write the  $K_a$  expression for each of the following in water:

(a)  $\text{HNO}_2$  (b)  $\text{CH}_3\text{COOH}$  (c)  $\text{HBrO}_2$ 

**18.12** Write the  $K_a$  expression for each of the following in water:

(a)  $\text{H}_2\text{PO}_4^-$  (b)  $\text{H}_3\text{PO}_2$  (c)  $\text{HSO}_4^-$ 

**18.13** Use Appendix C to rank the following in order of *increasing* acid strength:  $\text{HIO}_3$ ,  $\text{HI}$ ,  $\text{CH}_3\text{COOH}$ ,  $\text{HF}$ .

**18.14** Use Appendix C to rank the following in order of *decreasing* acid strength:  $\text{HClO}$ ,  $\text{HCl}$ ,  $\text{HCN}$ ,  $\text{HNO}_2$ .

**18.15** Classify each as a strong or weak acid or base:

(a)  $\text{H}_3\text{AsO}_4$  (b)  $\text{Sr}(\text{OH})_2$  (c)  $\text{HIO}$  (d)  $\text{HClO}_4$ 

**18.16** Classify each as a strong or weak acid or base:

(a)  $\text{CH}_3\text{NH}_2$  (b)  $\text{K}_2\text{O}$  (c)  $\text{HI}$  (d)  $\text{HCOOH}$ 

**18.17** Classify each as a strong or weak acid or base:

(a)  $\text{RbOH}$  (b)  $\text{HBr}$  (c)  $\text{H}_2\text{Te}$  (d)  $\text{HClO}$ 

**18.18** Classify each as a strong or weak acid or base:

(a)  $\text{HOCH}_2\text{CH}_2\text{NH}_2$  (b)  $\text{H}_2\text{SeO}_4$  (c)  $\text{HS}^-$  (d)  $\text{B}(\text{OH})_3$ 

## Autoionization of Water and the pH Scale

(Sample Problems 18.2 and 18.3)

## Concept Review Questions

**18.19** What is an autoionization reaction? Write equations for the autoionization reactions of  $\text{H}_2\text{O}$  and of  $\text{H}_2\text{SO}_4$ .

**18.20** What is the difference between  $K_c$  and  $K_w$  for the autoionization of water?

**18.21** (a) What is the change in pH when  $[\text{OH}^-]$  increases by a factor of 10? (b) What is the change in  $[\text{H}_3\text{O}^+]$  when the pH decreases by 3 units?

**18.22** Which solution has the higher pH? Explain.

- (a) A 0.1 *M* solution of an acid with  $K_a = 1 \times 10^{-4}$  or one with  $K_a = 4 \times 10^{-5}$   
 (b) A 0.1 *M* solution of an acid with  $pK_a = 3.0$  or one with  $pK_a = 3.5$   
 (c) A 0.1 *M* solution or a 0.01 *M* solution of a weak acid  
 (d) A 0.1 *M* solution of a weak acid or a 0.1 *M* solution of a strong acid  
 (e) A 0.1 *M* solution of an acid or a 0.01 *M* solution of a base  
 (f) A solution of pOH 6.0 or one of pOH 8.0

### Skill-Building Exercises (grouped in similar pairs)

**18.23** (a) What is the pH of 0.0111 *M* NaOH? Is the solution neutral, acidic, or basic? (b) What is the pOH of  $1.35 \times 10^{-3}$  *M* HCl? Is the solution neutral, acidic, or basic?

**18.24** (a) What is the pH of 0.0333 *M* HNO<sub>3</sub>? Is the solution neutral, acidic, or basic? (b) What is the pOH of 0.0347 *M* KOH? Is the solution neutral, acidic, or basic?

**18.25** (a) What is the pH of  $6.14 \times 10^{-3}$  *M* HI? Is the solution neutral, acidic, or basic? (b) What is the pOH of 2.55 *M* Ba(OH)<sub>2</sub>? Is the solution neutral, acidic, or basic?

**18.26** (a) What is the pH of  $7.52 \times 10^{-4}$  *M* CsOH? Is the solution neutral, acidic, or basic? (b) What is the pOH of  $1.59 \times 10^{-3}$  *M* HClO<sub>4</sub>? Is the solution neutral, acidic, or basic?

**18.27** (a) What are [H<sub>3</sub>O<sup>+</sup>], [OH<sup>-</sup>], and pOH in a solution with a pH of 9.85? (b) What are [H<sub>3</sub>O<sup>+</sup>], [OH<sup>-</sup>], and pH in a solution with a pOH of 9.43?

**18.28** (a) What are [H<sub>3</sub>O<sup>+</sup>], [OH<sup>-</sup>], and pOH in a solution with a pH of 3.47? (b) What are [H<sub>3</sub>O<sup>+</sup>], [OH<sup>-</sup>], and pH in a solution with a pOH of 4.33?

**18.29** (a) What are [H<sub>3</sub>O<sup>+</sup>], [OH<sup>-</sup>], and pOH in a solution with a pH of 4.77? (b) What are [H<sub>3</sub>O<sup>+</sup>], [OH<sup>-</sup>], and pH in a solution with a pOH of 5.65?

**18.30** (a) What are [H<sub>3</sub>O<sup>+</sup>], [OH<sup>-</sup>], and pOH in a solution with a pH of 8.97? (b) What are [H<sub>3</sub>O<sup>+</sup>], [OH<sup>-</sup>], and pH in a solution with a pOH of 11.27?

**18.31** How many moles of H<sub>3</sub>O<sup>+</sup> or OH<sup>-</sup> must you add to a liter of strong acid solution to adjust its pH from 3.15 to 3.65? Assume a negligible volume change.

**18.32** How many moles of H<sub>3</sub>O<sup>+</sup> or OH<sup>-</sup> must you add to a liter of strong base solution to adjust its pH from 9.33 to 9.07? Assume a negligible volume change.

**18.33** How many moles of H<sub>3</sub>O<sup>+</sup> or OH<sup>-</sup> must you add to 5.6 L of strong acid solution to adjust its pH from 4.52 to 5.25? Assume a negligible volume change.

**18.34** How many moles of H<sub>3</sub>O<sup>+</sup> or OH<sup>-</sup> must you add to 87.5 mL of strong base solution to adjust its pH from 8.92 to 8.45? Assume a negligible volume change.

### Problems in Context

**18.35** The two molecular scenes shown depict the relative concentrations of H<sub>3</sub>O<sup>+</sup> (purple) in solutions of the same volume (with counter ions and solvent molecules omitted for clarity). If the pH in scene A is 4.8, what is the pH in scene B?

**18.36** Like any equilibrium constant,  $K_w$  changes with temperature. (a) Given that autoionization is endothermic, how does  $K_w$  change with rising  $T$ ? Explain with a reaction that includes heat as reactant or product. (b) In many medical applications, the value of  $K_w$  at 37°C (body temperature) may be more appropriate than the value at 25°C,  $1.0 \times 10^{-14}$ . The pH of pure water at 37°C is 6.80. Calculate  $K_w$ , pOH, and [OH<sup>-</sup>] at this temperature.

### Proton Transfer and the Brønsted-Lowry Acid-Base Definition (Sample Problems 18.4 to 18.6)

#### Concept Review Questions

**18.37** How are the Arrhenius and Brønsted-Lowry acid-base definitions different? How are they similar? Name two Brønsted-Lowry bases that are not Arrhenius bases. Can you do the same for acids? Explain.

**18.38** What is a conjugate acid-base pair? What is the relationship between the two members of the pair?

**18.39** (a) A Brønsted-Lowry acid-base reaction proceeds in the net direction in which a stronger acid and stronger base form a weaker acid and weaker base. Explain.

(b) The molecular scene at right depicts an aqueous solution of two conjugate acid-base pairs: HA/A<sup>-</sup> and HB/B<sup>-</sup>. The base in the first pair is represented by red spheres, and the base in the second pair by green spheres; solvent molecules are omitted for clarity. Which is the stronger acid? The stronger base? Explain.

**18.40** What is an amphiprotic species? Name one and write balanced equations that show why it is amphiprotic.

### Skill-Building Exercises (grouped in similar pairs)

**18.41** Write balanced equations and  $K_a$  expressions for these Brønsted-Lowry acids in water:

- (a) H<sub>3</sub>PO<sub>4</sub>      (b) C<sub>6</sub>H<sub>5</sub>COOH      (c) HSO<sub>4</sub><sup>-</sup>

**18.42** Write balanced equations and  $K_a$  expressions for these Brønsted-Lowry acids in water:

- (a) HCOOH      (b) HClO<sub>3</sub>      (c) H<sub>2</sub>AsO<sub>4</sub><sup>-</sup>

**18.43** Give the formula of the conjugate base:

- (a) HCl      (b) H<sub>2</sub>CO<sub>3</sub>      (c) H<sub>2</sub>O

**18.44** Give the formula of the conjugate base:

- (a) HPO<sub>4</sub><sup>2-</sup>      (b) NH<sub>4</sub><sup>+</sup>      (c) HS<sup>-</sup>

**18.45** Give the formula of the conjugate acid:

- (a) NH<sub>3</sub>      (b) NH<sub>2</sub><sup>-</sup>      (c) nicotine, C<sub>10</sub>H<sub>14</sub>N<sub>2</sub>

**18.46** Give the formula of the conjugate acid:

- (a) O<sup>2-</sup>      (b) SO<sub>4</sub><sup>2-</sup>      (c) H<sub>2</sub>O

**18.47** In each equation, label the acids, bases, and conjugate pairs:

- (a)  $\text{HCl} + \text{H}_2\text{O} \rightleftharpoons \text{Cl}^- + \text{H}_3\text{O}^+$   
 (b)  $\text{HClO}_4 + \text{H}_2\text{SO}_4 \rightleftharpoons \text{ClO}_4^- + \text{H}_3\text{SO}_4^+$   
 (c)  $\text{HPO}_4^{2-} + \text{H}_2\text{SO}_4 \rightleftharpoons \text{H}_2\text{PO}_4^- + \text{HSO}_4^-$

**18.48** In each equation, label the acids, bases, and conjugate pairs:

- (a)  $\text{NH}_3 + \text{HNO}_3 \rightleftharpoons \text{NH}_4^+ + \text{NO}_3^-$   
 (b)  $\text{O}^{2-} + \text{H}_2\text{O} \rightleftharpoons \text{OH}^- + \text{OH}^-$   
 (c)  $\text{NH}_4^+ + \text{BrO}_3^- \rightleftharpoons \text{NH}_3 + \text{HBrO}_3$

**18.49** In each equation, label the acids, bases, and conjugate pairs:

- (a)  $\text{NH}_3 + \text{H}_3\text{PO}_4 \rightleftharpoons \text{NH}_4^+ + \text{H}_2\text{PO}_4^-$   
 (b)  $\text{CH}_3\text{O}^- + \text{NH}_3 \rightleftharpoons \text{CH}_3\text{OH} + \text{NH}_2^-$   
 (c)  $\text{HPO}_4^{2-} + \text{HSO}_4^- \rightleftharpoons \text{H}_2\text{PO}_4^- + \text{SO}_4^{2-}$

**18.50** In each equation, label the acids, bases, and conjugate pairs:

- (a)  $\text{NH}_4^+ + \text{CN}^- \rightleftharpoons \text{NH}_3 + \text{HCN}$   
 (b)  $\text{H}_2\text{O} + \text{HS}^- \rightleftharpoons \text{OH}^- + \text{H}_2\text{S}$   
 (c)  $\text{HSO}_3^- + \text{CH}_3\text{NH}_2 \rightleftharpoons \text{SO}_3^{2-} + \text{CH}_3\text{NH}_3^+$

**18.51** Write balanced net ionic equations for the following reactions, and label the conjugate acid-base pairs:

- (a)  $\text{NaOH}(aq) + \text{NaH}_2\text{PO}_4(aq) \rightleftharpoons \text{H}_2\text{O}(l) + \text{Na}_2\text{HPO}_4(aq)$   
 (b)  $\text{KHSO}_4(aq) + \text{K}_2\text{CO}_3(aq) \rightleftharpoons \text{K}_2\text{SO}_4(aq) + \text{KHCO}_3(aq)$

**18.52** Write balanced net ionic equations for the following reactions, and label the conjugate acid-base pairs:

- (a)  $\text{HNO}_3(aq) + \text{Li}_2\text{CO}_3(aq) \rightleftharpoons \text{LiNO}_3(aq) + \text{LiHCO}_3(aq)$   
 (b)  $2\text{NH}_4\text{Cl}(aq) + \text{Ba}(\text{OH})_2(aq) \rightleftharpoons 2\text{H}_2\text{O}(l) + \text{BaCl}_2(aq) + 2\text{NH}_3(aq)$

**18.53** The following aqueous species constitute two conjugate acid-base pairs. Use them to write one acid-base reaction with  $K_c > 1$  and another with  $K_c < 1$ :  $\text{HS}^-$ ,  $\text{Cl}^-$ ,  $\text{HCl}$ ,  $\text{H}_2\text{S}$ .

**18.54** The following aqueous species constitute two conjugate acid-base pairs. Use them to write one acid-base reaction with  $K_c > 1$  and another with  $K_c < 1$ :  $\text{NO}_3^-$ ,  $\text{F}^-$ ,  $\text{HF}$ ,  $\text{HNO}_3$ .

**18.55** Use Figure 18.8 to determine whether  $K_c > 1$  for

- (a)  $\text{HCl} + \text{NH}_3 \rightleftharpoons \text{NH}_4^+ + \text{Cl}^-$   
 (b)  $\text{H}_2\text{SO}_3 + \text{NH}_3 \rightleftharpoons \text{HSO}_3^- + \text{NH}_4^+$

**18.56** Use Figure 18.8 to determine whether  $K_c > 1$  for

- (a)  $\text{OH}^- + \text{HS}^- \rightleftharpoons \text{H}_2\text{O} + \text{S}^{2-}$   
 (b)  $\text{HCN} + \text{HCO}_3^- \rightleftharpoons \text{H}_2\text{CO}_3 + \text{CN}^-$

**18.57** Use Figure 18.8 to determine whether  $K_c < 1$  for

- (a)  $\text{NH}_4^+ + \text{HPO}_4^{2-} \rightleftharpoons \text{NH}_3 + \text{H}_2\text{PO}_4^-$   
 (b)  $\text{HSO}_3^- + \text{HS}^- \rightleftharpoons \text{H}_2\text{SO}_3 + \text{S}^{2-}$

**18.58** Use Figure 18.8 to determine whether  $K_c < 1$  for

- (a)  $\text{H}_2\text{PO}_4^- + \text{F}^- \rightleftharpoons \text{HPO}_4^{2-} + \text{HF}$   
 (b)  $\text{CH}_3\text{COO}^- + \text{HSO}_4^- \rightleftharpoons \text{CH}_3\text{COOH} + \text{SO}_4^{2-}$

### Solving Problems Involving Weak-Acid Equilibria

(Sample Problems 18.7 to 18.10)

#### Concept Review Questions

**18.59** In each of the following cases, is the concentration of acid before and after dissociation nearly the same or very different? Explain your reasoning: (a) a concentrated solution of a strong acid; (b) a concentrated solution of a weak acid; (c) a dilute solution of a weak acid; (d) a dilute solution of a strong acid.

**18.60** A sample of  $0.0001\text{ M HCl}$  has  $[\text{H}_3\text{O}^+]$  close to that of a sample of  $0.1\text{ M CH}_3\text{COOH}$ . Are acetic acid and hydrochloric acid equally strong in these samples? Explain.

**18.61** A  $0.15\text{ M}$  solution of HA (blue and green) is 33% dissociated. Which of the scenes below represents a sample of that solution after it is diluted with water? (An actual weak acid does not have a percent dissociation this high.)

**18.62** In which of the following solutions will  $[\text{H}_3\text{O}^+]$  be approximately equal to  $[\text{CH}_3\text{COO}^-]$ : (a)  $0.1\text{ M CH}_3\text{COOH}$ ; (b)  $1 \times 10^{-7}\text{ M CH}_3\text{COOH}$ ; (c) a solution containing both  $0.1\text{ M CH}_3\text{COOH}$  and  $0.1\text{ M CH}_3\text{COONa}$ ? Explain.

**18.63** Why do successive  $K_a$ 's decrease for all polyprotic acids?

#### Skill-Building Exercises (grouped in similar pairs)

**18.64** A  $0.15\text{ M}$  solution of butanoic acid,  $\text{CH}_3\text{CH}_2\text{CH}_2\text{COOH}$ , contains  $1.51 \times 10^{-3}\text{ M H}_3\text{O}^+$ . What is the  $K_a$  of butanoic acid?

**18.65** A  $0.035\text{ M}$  solution of a weak acid (HA) has a pH of 4.88. What is the  $K_a$  of the acid?

**18.66** Nitrous acid,  $\text{HNO}_2$ , has a  $K_a$  of  $7.1 \times 10^{-4}$ . What are  $[\text{H}_3\text{O}^+]$ ,  $[\text{NO}_2^-]$ , and  $[\text{OH}^-]$  in  $0.60\text{ M HNO}_2$ ?

**18.67** Hydrofluoric acid, HF, has a  $K_a$  of  $6.8 \times 10^{-4}$ . What are  $[\text{H}_3\text{O}^+]$ ,  $[\text{F}^-]$ , and  $[\text{OH}^-]$  in  $0.75\text{ M HF}$ ?

**18.68** Chloroacetic acid,  $\text{ClCH}_2\text{COOH}$ , has a  $\text{p}K_a$  of 2.87. What are  $[\text{H}_3\text{O}^+]$ , pH,  $[\text{ClCH}_2\text{COO}^-]$ , and  $[\text{ClCH}_2\text{COOH}]$  in  $1.25\text{ M ClCH}_2\text{COOH}$ ?

**18.69** Hypochlorous acid, HClO, has a  $\text{p}K_a$  of 7.54. What are  $[\text{H}_3\text{O}^+]$ , pH,  $[\text{ClO}^-]$ , and  $[\text{HClO}]$  in  $0.115\text{ M HClO}$ ?

**18.70** In a  $0.20\text{ M}$  solution, a weak acid is 3.0% dissociated.

- (a) Calculate the  $[\text{H}_3\text{O}^+]$ , pH,  $[\text{OH}^-]$ , and pOH of the solution.  
 (b) Calculate  $K_a$  of the acid.

**18.71** In a  $0.735\text{ M}$  solution, a weak acid is 12.5% dissociated.

- (a) Calculate the  $[\text{H}_3\text{O}^+]$ , pH,  $[\text{OH}^-]$ , and pOH of the solution.  
 (b) Calculate  $K_a$  of the acid.

**18.72** A  $0.250\text{-mol}$  sample of HX is dissolved in enough  $\text{H}_2\text{O}$  to form  $655\text{ mL}$  of solution. If the pH of the solution is 3.54, what is the  $K_a$  of HX?

**18.73** A  $4.85 \times 10^{-3}\text{-mol}$  sample of HY is dissolved in enough  $\text{H}_2\text{O}$  to form  $0.095\text{ L}$  of solution. If the pH of the solution is 2.68, what is the  $K_a$  of HY?

**18.74** The weak acid HZ has a  $K_a$  of  $2.55 \times 10^{-4}$ .

- (a) Calculate the pH of  $0.075\text{ M HZ}$ .  
 (b) Calculate the pOH of  $0.045\text{ M HZ}$ .

**18.75** The weak acid HQ has a  $\text{p}K_a$  of 4.89.

- (a) Calculate the  $[\text{H}_3\text{O}^+]$  of  $3.5 \times 10^{-2}\text{ M HQ}$ .  
 (b) Calculate the  $[\text{OH}^-]$  of  $0.65\text{ M HQ}$ .

**18.76** (a) Calculate the pH of  $0.175\text{ M HY}$ , if  $K_a = 1.50 \times 10^{-4}$ .  
 (b) Calculate the pOH of  $0.175\text{ M HX}$ , if  $K_a = 2.00 \times 10^{-2}$ .

**18.77** (a) Calculate the pH of  $0.55\text{ M HCN}$ , if  $K_a = 6.2 \times 10^{-10}$ .  
 (b) Calculate the pOH of  $0.044\text{ M HIO}_3$ , if  $K_a = 0.16$ .

**18.78** Use Appendix C to calculate the percent dissociation of 0.55 *M* benzoic acid, C<sub>6</sub>H<sub>5</sub>COOH.

**18.79** Use Appendix C to calculate the percent dissociation of 0.050 *M* CH<sub>3</sub>COOH.

**18.80** Use Appendix C to calculate [H<sub>2</sub>S], [HS<sup>-</sup>], [S<sup>2-</sup>], [H<sub>3</sub>O<sup>+</sup>], pH, [OH<sup>-</sup>], and pOH in a 0.10 *M* solution of the diprotic acid hydrosulfuric acid.

**18.81** Use Appendix C to calculate [H<sub>2</sub>C<sub>3</sub>H<sub>2</sub>O<sub>4</sub>], [HC<sub>3</sub>H<sub>2</sub>O<sub>4</sub><sup>-</sup>], [C<sub>3</sub>H<sub>2</sub>O<sub>4</sub><sup>2-</sup>], [H<sub>3</sub>O<sup>+</sup>], pH, [OH<sup>-</sup>], and pOH in a 0.200 *M* solution of the diprotic acid malonic acid.

### Problems in Context

**18.82** Acetylsalicylic acid (aspirin), HC<sub>9</sub>H<sub>7</sub>O<sub>4</sub>, is the most widely used pain reliever and fever reducer. Find the pH of 0.018 *M* aqueous aspirin at body temperature (*K*<sub>a</sub> at 37°C = 3.6 × 10<sup>-4</sup>).

**18.83** Formic acid, HCOOH, the simplest carboxylic acid, is used in the textile and rubber industries and is secreted as a defense by many species of ants (family *Formicidae*). Calculate the percent dissociation of 0.75 *M* HCOOH.

### Molecular Properties and Acid Strength

#### Concept Review Questions

**18.84** Across a period, how does the electronegativity of a non-metal affect the acidity of its binary hydride?

**18.85** How does the atomic size of a nonmetal affect the acidity of its binary hydride?

**18.86** A strong acid has a weak bond to its acidic proton, whereas a weak acid has a strong bond to its acidic proton. Explain.

**18.87** Perchloric acid, HClO<sub>4</sub>, is the strongest of the halogen oxoacids, and hypiodous acid, HIO, is the weakest. What two factors govern this difference in acid strength?

#### Skill-Building Exercises (grouped in similar pairs)

**18.88** Choose the *stronger* acid in each of the following pairs:  
(a) H<sub>2</sub>SeO<sub>3</sub> or H<sub>2</sub>SeO<sub>4</sub> (b) H<sub>3</sub>PO<sub>4</sub> or H<sub>3</sub>AsO<sub>4</sub> (c) H<sub>2</sub>S or H<sub>2</sub>Te

**18.89** Choose the *weaker* acid in each of the following pairs:  
(a) HBr or H<sub>2</sub>Se (b) HClO<sub>4</sub> or H<sub>2</sub>SO<sub>4</sub> (c) H<sub>2</sub>SO<sub>3</sub> or H<sub>2</sub>SO<sub>4</sub>

**18.90** Choose the *stronger* acid in each of the following pairs:  
(a) H<sub>2</sub>Se or H<sub>3</sub>As (b) B(OH)<sub>3</sub> or Al(OH)<sub>3</sub> (c) HBrO<sub>2</sub> or HBrO

**18.91** Choose the *weaker* acid in each of the following pairs:  
(a) HI or HBr (b) H<sub>3</sub>AsO<sub>4</sub> or H<sub>2</sub>SeO<sub>4</sub> (c) HNO<sub>3</sub> or HNO<sub>2</sub>

**18.92** Use Appendix C to choose the solution with the *lower* pH:  
(a) 0.5 *M* CuBr<sub>2</sub> or 0.5 *M* AlBr<sub>3</sub>  
(b) 0.3 *M* ZnCl<sub>2</sub> or 0.3 *M* SnCl<sub>2</sub>

**18.93** Use Appendix C to choose the solution with the *lower* pH:  
(a) 0.1 *M* FeCl<sub>3</sub> or 0.1 *M* AlCl<sub>3</sub>  
(b) 0.1 *M* BeCl<sub>2</sub> or 0.1 *M* CaCl<sub>2</sub>

**18.94** Use Appendix C to choose the solution with the *higher* pH:  
(a) 0.2 *M* Ni(NO<sub>3</sub>)<sub>2</sub> or 0.2 *M* Co(NO<sub>3</sub>)<sub>2</sub>  
(b) 0.35 *M* Al(NO<sub>3</sub>)<sub>3</sub> or 0.35 *M* Cr(NO<sub>3</sub>)<sub>3</sub>

**18.95** Use Appendix C to choose the solution with the *higher* pH:  
(a) 0.1 *M* NiCl<sub>2</sub> or 0.1 *M* NaCl  
(b) 0.1 *M* Sn(NO<sub>3</sub>)<sub>2</sub> or 0.1 *M* Co(NO<sub>3</sub>)<sub>2</sub>

### Weak Bases and Their Relation to Weak Acids

(Sample Problems 18.11 and 18.12)

#### Concept Review Questions

**18.96** What is the key structural feature of all Brønsted-Lowry bases? How does this feature function in an acid-base reaction?

**18.97** Why are most anions basic in H<sub>2</sub>O? Give formulas of four anions that are not basic.

**18.98** Except for the Na<sup>+</sup> spectator ion, aqueous solutions of CH<sub>3</sub>COOH and CH<sub>3</sub>COONa contain the same species. (a) What are the species (other than H<sub>2</sub>O)? (b) Why is 0.1 *M* CH<sub>3</sub>COOH acidic and 0.1 *M* CH<sub>3</sub>COONa basic?

#### Skill-Building Exercises (grouped in similar pairs)

**18.99** Write balanced equations and *K*<sub>b</sub> expressions for these Brønsted-Lowry bases in water:

(a) Pyridine, C<sub>5</sub>H<sub>5</sub>N (b) CO<sub>3</sub><sup>2-</sup>

**18.100** Write balanced equations and *K*<sub>b</sub> expressions for these Brønsted-Lowry bases in water:

(a) Benzoate ion, C<sub>6</sub>H<sub>5</sub>COO<sup>-</sup> (b) (CH<sub>3</sub>)<sub>3</sub>N

**18.101** Write balanced equations and *K*<sub>b</sub> expressions for these Brønsted-Lowry bases in water:

(a) Hydroxylamine, HO—NH<sub>2</sub> (b) HPO<sub>4</sub><sup>2-</sup>

**18.102** Write balanced equations and *K*<sub>b</sub> expressions for these Brønsted-Lowry bases in water:

(a) Guanidine, (H<sub>2</sub>N)<sub>2</sub>C=NH (the double-bonded N is more basic)  
(b) Acetylide ion, HC≡C<sup>-</sup>

**18.103** What is the pH of 0.070 *M* dimethylamine?

**18.104** What is the pH of 0.12 *M* diethylamine?

**18.105** What is the pH of 0.25 *M* ethanolamine?

**18.106** What is the pH of 0.26 *M* aniline?

**18.107** (a) What is the *K*<sub>b</sub> of the acetate ion?

(b) What is the *K*<sub>a</sub> of the anilinium ion, C<sub>6</sub>H<sub>5</sub>NH<sub>3</sub><sup>+</sup>?

**18.108** (a) What is the *K*<sub>b</sub> of the benzoate ion, C<sub>6</sub>H<sub>5</sub>COO<sup>-</sup>?

(b) What is the *K*<sub>a</sub> of the 2-hydroxyethylammonium ion, HOCH<sub>2</sub>CH<sub>2</sub>NH<sub>3</sub><sup>+</sup> (*pK*<sub>b</sub> of HOCH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub> = 4.49)?

**18.109** (a) What is the *pK*<sub>b</sub> of ClO<sub>2</sub><sup>-</sup>?

(b) What is the *pK*<sub>a</sub> of the dimethylammonium ion, (CH<sub>3</sub>)<sub>2</sub>NH<sub>2</sub><sup>+</sup>?

**18.110** (a) What is the *pK*<sub>b</sub> of NO<sub>2</sub><sup>-</sup>?

(b) What is the *pK*<sub>a</sub> of the hydrazinium ion, H<sub>2</sub>N—NH<sub>3</sub><sup>+</sup> (*K*<sub>b</sub> of hydrazine = 8.5 × 10<sup>-7</sup>)?

**18.111** (a) What is the pH of 0.150 *M* KCN?

(b) What is the pH of 0.40 *M* triethylammonium chloride, (CH<sub>3</sub>CH<sub>2</sub>)<sub>3</sub>NHCl?

**18.112** (a) What is the pH of 0.100 *M* sodium phenolate, C<sub>6</sub>H<sub>5</sub>ONa, the sodium salt of phenol?

(b) What is the pH of 0.15 *M* methylammonium bromide, CH<sub>3</sub>NH<sub>3</sub>Br (*K*<sub>b</sub> of CH<sub>3</sub>NH<sub>2</sub> = 4.4 × 10<sup>-4</sup>)?

**18.113** (a) What is the pH of 0.65 *M* potassium formate, HCOOK?

(b) What is the pH of 0.85 *M* NH<sub>4</sub>Br?

**18.114** (a) What is the pH of 0.75 *M* NaF?

(b) What is the pH of 0.88 *M* pyridinium chloride, C<sub>5</sub>H<sub>5</sub>NHCl?

**Problems in Context**

**18.115** Sodium hypochlorite solution, sold as chlorine bleach, is potentially dangerous because of the basicity of  $\text{ClO}^-$ , the active bleaching ingredient. What is  $[\text{OH}^-]$  in an aqueous solution that is 6.5%  $\text{NaClO}$  by mass? What is the pH of the solution? (Assume that  $d$  of the solution is 1.0 g/mL.)

**18.116** Codeine ( $\text{C}_{18}\text{H}_{21}\text{NO}_3$ ) is a narcotic pain reliever that forms a salt with  $\text{HCl}$ . What is the pH of 0.050  $M$  codeine hydrochloride ( $\text{p}K_b$  of codeine = 5.80)?

**Acid-Base Properties of Salt Solutions**

(Sample Problems 18.13 and 18.14)

**Concept Review Questions**

**18.117** What determines whether an aqueous solution of a salt will be acidic, basic, or neutral? Give an example of each type of salt.

**18.118** Why is aqueous  $\text{NaF}$  basic but aqueous  $\text{NaCl}$  neutral?

**18.119** The  $\text{NH}_4^+$  ion forms acidic solutions, and the  $\text{CH}_3\text{COO}^-$  ion forms basic solutions. However, a solution of ammonium acetate is almost neutral. Do all of the ammonium salts of weak acids form neutral solutions? Explain your answer.

**Skill-Building Exercises (grouped in similar pairs)**

**18.120** Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a)  $\text{KBr}$ ; (b)  $\text{NH}_4\text{I}$ ; (c)  $\text{KCN}$ .

**18.121** Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a)  $\text{SnCl}_2$ ; (b)  $\text{NaHS}$ ; (c)  $\text{Zn}(\text{CH}_3\text{COO})_2$ .

**18.122** Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a)  $\text{Na}_2\text{CO}_3$ ; (b)  $\text{CaCl}_2$ ; (c)  $\text{Cu}(\text{NO}_3)_2$ .

**18.123** Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a)  $\text{CH}_3\text{NH}_3\text{Cl}$ ; (b)  $\text{LiClO}_4$ ; (c)  $\text{CoF}_2$ .

**18.124** Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a)  $\text{SrBr}_2$ ; (b)  $\text{Ba}(\text{CH}_3\text{COO})_2$ ; (c)  $(\text{CH}_3)_2\text{NH}_2\text{Br}$ .

**18.125** Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a)  $\text{Fe}(\text{HCOO})_3$ ; (b)  $\text{KHCO}_3$ ; (c)  $\text{K}_2\text{S}$ .

**18.126** Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a)  $(\text{NH}_4)_3\text{PO}_4$ ; (b)  $\text{Na}_2\text{SO}_4$ ; (c)  $\text{LiClO}$ .

**18.127** Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a)  $\text{Pb}(\text{CH}_3\text{COO})_2$ ; (b)  $\text{Cr}(\text{NO}_2)_3$ ; (c)  $\text{CsI}$ .

**18.128** Rank the following salts in order of increasing pH of their 0.1  $M$  aqueous solutions:

- (a)  $\text{KNO}_3$ ,  $\text{K}_2\text{SO}_3$ ,  $\text{K}_2\text{S}$ ,  $\text{Fe}(\text{NO}_3)_2$   
 (b)  $\text{NH}_4\text{NO}_3$ ,  $\text{NaHSO}_4$ ,  $\text{NaHCO}_3$ ,  $\text{Na}_2\text{CO}_3$

**18.129** Rank the following salts in order of decreasing pH of their 0.1  $M$  aqueous solutions:

- (a)  $\text{FeCl}_2$ ,  $\text{FeCl}_3$ ,  $\text{MgCl}_2$ ,  $\text{KClO}_2$   
 (b)  $\text{NH}_4\text{Br}$ ,  $\text{NaBrO}_2$ ,  $\text{NaBr}$ ,  $\text{NaClO}_2$

**Generalizing the Brønsted-Lowry Concept: The Leveling Effect****Concept Review Questions**

**18.130** Methoxide ion,  $\text{CH}_3\text{O}^-$ , and amide ion,  $\text{NH}_2^-$ , are very strong bases that are “leveled” by water. What does this mean? Write the reactions that occur in the leveling process. What species do the two leveled solutions have in common?

**18.131** Explain the differing extents of dissociation of  $\text{H}_2\text{SO}_4$  in  $\text{CH}_3\text{COOH}$ ,  $\text{H}_2\text{O}$ , and  $\text{NH}_3$ .

**18.132** In  $\text{H}_2\text{O}$ ,  $\text{HF}$  is weak and the other hydrohalic acids are equally strong. In  $\text{NH}_3$ , however, all the hydrohalic acids are equally strong. Explain.

**Electron-Pair Donation and the Lewis Acid-Base Definition**

(Sample Problem 18.15)

**Concept Review Questions**

**18.133** What feature must a molecule or ion have in order to act as a Lewis base? A Lewis acid? Explain the roles of these features.

**18.134** How do Lewis acids differ from Brønsted-Lowry acids? How are they similar? Do Lewis bases differ from Brønsted-Lowry bases? Explain.

**18.135** (a) Is a weak Brønsted-Lowry base necessarily a weak Lewis base? Explain with an example.

(b) Identify the Lewis bases in the following reaction:

(c) Given that  $K_c > 1$  for the reaction in part (b), which Lewis base is stronger?

**18.136** In which of the three acid-base concepts can water be a product of an acid-base reaction? In which is it the only product?

**18.137** (a) Give an example of a *substance* that is a base in two of the three acid-base definitions, but not in the third.

(b) Give an example of a *substance* that is an acid in one of the three acid-base definitions, but not in the other two.

**Skill-Building Exercises (grouped in similar pairs)**

**18.138** Which are Lewis acids and which are Lewis bases?

- (a)  $\text{Cu}^{2+}$       (b)  $\text{Cl}^-$       (c)  $\text{SnCl}_2$       (d)  $\text{OF}_2$

**18.139** Which are Lewis acids and which are Lewis bases?

- (a)  $\text{Na}^+$       (b)  $\text{NH}_3$       (c)  $\text{CN}^-$       (d)  $\text{BF}_3$

**18.140** Which are Lewis acids and which are Lewis bases?

- (a)  $\text{BF}_3$       (b)  $\text{S}^{2-}$       (c)  $\text{SO}_3^{2-}$       (d)  $\text{SO}_3$

**18.141** Which are Lewis acids and which are Lewis bases?

- (a)  $\text{Mg}^{2+}$       (b)  $\text{OH}^-$       (c)  $\text{SiF}_4$       (d)  $\text{BeCl}_2$

**18.142** Identify the Lewis acid and Lewis base in each reaction:

- (a)  $\text{Na}^+ + 6\text{H}_2\text{O} \rightleftharpoons \text{Na}(\text{H}_2\text{O})_6^+$       (b)  $\text{CO}_2 + \text{H}_2\text{O} \rightleftharpoons \text{H}_2\text{CO}_3$   
 (c)  $\text{F}^- + \text{BF}_3 \rightleftharpoons \text{BF}_4^-$

**18.143** Identify the Lewis acid and Lewis base in each reaction:

- (a)  $\text{Fe}^{3+} + 2\text{H}_2\text{O} \rightleftharpoons \text{FeOH}^{2+} + \text{H}_3\text{O}^+$   
 (b)  $\text{H}_2\text{O} + \text{H}^- \rightleftharpoons \text{OH}^- + \text{H}_2$   
 (c)  $4\text{CO} + \text{Ni} \rightleftharpoons \text{Ni}(\text{CO})_4$

**18.144** Classify the following as Arrhenius, Brønsted-Lowry, or Lewis acid-base reactions. A reaction may fit all, two, one, or none of the categories:

- (a)  $\text{Ag}^+ + 2\text{NH}_3 \rightleftharpoons \text{Ag}(\text{NH}_3)_2^+$   
 (b)  $\text{H}_2\text{SO}_4 + \text{NH}_3 \rightleftharpoons \text{HSO}_4^- + \text{NH}_4^+$   
 (c)  $2\text{HCl} \rightleftharpoons \text{H}_2 + \text{Cl}_2$   
 (d)  $\text{AlCl}_3 + \text{Cl}^- \rightleftharpoons \text{AlCl}_4^-$

**18.145** Classify the following as Arrhenius, Brønsted-Lowry, or Lewis acid-base reactions. A reaction may fit all, two, one, or none of the categories:

- (a)  $\text{Cu}^{2+} + 4\text{Cl}^- \rightleftharpoons \text{CuCl}_4^{2-}$   
 (b)  $\text{Al}(\text{OH})_3 + 3\text{HNO}_3 \rightleftharpoons \text{Al}^{3+} + 3\text{H}_2\text{O} + 3\text{NO}_3^-$   
 (c)  $\text{N}_2 + 3\text{H}_2 \rightleftharpoons 2\text{NH}_3$   
 (d)  $\text{CN}^- + \text{H}_2\text{O} \rightleftharpoons \text{HCN} + \text{OH}^-$

### Comprehensive Problems

**18.146** Chloral ( $\text{Cl}_3\text{C}-\text{CH}=\text{O}$ ) forms a monohydrate, chloral hydrate, the sleep-inducing depressant called “knockout drops” in old movies. (a) Write two possible structures for chloral hydrate, one involving hydrogen bonding and one that is a Lewis adduct. (b) What spectroscopic method could be used to identify the real structure? Explain.

**18.147** In humans, blood pH is maintained within a narrow range: *acidosis* occurs if the blood pH is below 7.35, and *alkalosis* occurs if the pH is above 7.45. Given that the  $\text{p}K_w$  of blood is 13.63 at  $37^\circ\text{C}$  (body temperature), what is the normal range of  $[\text{H}_3\text{O}^+]$  and of  $[\text{OH}^-]$  in blood?

**18.148** The disinfectant phenol,  $\text{C}_6\text{H}_5\text{OH}$ , has a  $\text{p}K_a$  of 10.0 in water, but 14.4 in methanol.

- (a) Why are the values different?  
 (b) Is methanol a stronger or weaker base than water?  
 (c) Write the dissociation reaction of phenol in methanol.  
 (d) Write an expression for the autoionization constant of methanol.

**18.149** When carbon dioxide dissolves in water, it undergoes a multistep equilibrium process, with  $K_{\text{overall}} = 4.5 \times 10^{-7}$ , which is simplified to the following:

- (a) Classify each step as a Lewis or a Brønsted-Lowry reaction.  
 (b) What is the pH of nonpolluted rainwater in equilibrium with clean air ( $P_{\text{CO}_2}$  in clean air =  $4 \times 10^{-4}$  atm; Henry's law constant for  $\text{CO}_2$  at  $25^\circ\text{C}$  is  $0.033$  mol/L·atm)?  
 (c) What is  $[\text{CO}_3^{2-}]$  in rainwater ( $K_a$  of  $\text{HCO}_3^- = 4.7 \times 10^{-11}$ )?  
 (d) If the partial pressure of  $\text{CO}_2$  in clean air doubles in the next few decades, what will the pH of rainwater become?

**18.150** Seashells are mostly calcium carbonate, which reacts with  $\text{H}_3\text{O}^+$  according to the equation

If  $K_w$  increases at higher pressure, will seashells dissolve more rapidly near the surface of the ocean or at great depths? Explain.

**18.151** Many molecules with central atoms from Period 3 or higher take part in Lewis acid-base reactions in which the central atom expands its valence shell.  $\text{SnCl}_4$  reacts with  $(\text{CH}_3)_3\text{N}$  as follows:

- (a) Identify the Lewis acid and the Lewis base in the reaction.  
 (b) Give the *nl* designation of the sublevel of the central atom in the acid before it accepts the lone pair.

**18.152** A chemist makes four successive ten-fold dilutions of  $1.0 \times 10^{-5} M$  HCl. Calculate the pH of the original solution and of each diluted solution (through  $1.0 \times 10^{-9} M$  HCl).

**18.153** Chlorobenzene,  $\text{C}_6\text{H}_5\text{Cl}$ , is a key intermediate in the manufacture of dyes and pesticides. It is made by the chlorination of benzene, catalyzed by  $\text{FeCl}_3$ , in this series of steps:

- (1)  $\text{Cl}_2 + \text{FeCl}_3 \rightleftharpoons \text{FeCl}_5$  (or  $\text{Cl}^+\text{FeCl}_4^-$ )  
 (2)  $\text{C}_6\text{H}_6 + \text{Cl}^+\text{FeCl}_4^- \rightleftharpoons \text{C}_6\text{H}_6\text{Cl}^+ + \text{FeCl}_4^-$   
 (3)  $\text{C}_6\text{H}_6\text{Cl}^+ \rightleftharpoons \text{C}_6\text{H}_5\text{Cl} + \text{H}^+$   
 (4)  $\text{H}^+ + \text{FeCl}_4^- \rightleftharpoons \text{HCl} + \text{FeCl}_3$

- (a) Which of the step(s) is (are) Lewis acid-base reactions?  
 (b) Identify the Lewis acids and bases in each of those steps.

**18.154** The beakers shown below contain 0.300 L of aqueous solutions of a moderately weak acid HY. Each particle represents 0.010 mol; solvent molecules are omitted for clarity. (a) The reaction in beaker A is at equilibrium. Calculate  $Q$  for the reactions in beakers B, C, and D to determine which, if any, is also at equilibrium. (b) For any not at equilibrium, in which direction does the reaction proceed? (c) Does dilution affect the extent of dissociation of a weak acid? Explain.

**18.155** The strength of an acid or base is related to its strength as an electrolyte. (a) Is the electrical conductivity of  $0.1 M$  HCl higher, lower, or the same as that of  $0.1 M$   $\text{CH}_3\text{COOH}$ ? Explain.  
 (b) Is the electrical conductivity of  $1 \times 10^{-7} M$  HCl higher, lower, or the same as that of  $1 \times 10^{-7} M$   $\text{CH}_3\text{COOH}$ ? Explain.

**18.156** Esters,  $\text{RCOOR}'$ , are formed by the reaction of carboxylic acids,  $\text{RCOOH}$ , and alcohols,  $\text{R}'\text{OH}$ , where R and R' are hydrocarbon groups. Many esters are responsible for the odors of fruit and, thus, have important uses in the food and cosmetics industries. The first two steps in the mechanism of ester formation are

Identify the Lewis acids and Lewis bases in these two steps.

**18.157** Three beakers contain 100. mL of  $0.10 M$  HCl,  $\text{HClO}_2$ , and HClO, respectively. (a) Find the pH of each. (b) Describe quantitatively how to make the pH equal in the beakers through the addition of water only.

**18.158** Human urine has a normal pH of 6.2. If a person eliminates an average of 1250. mL of urine per day, how many  $\text{H}^+$  ions are eliminated per week?

**18.159** Liquid ammonia autoionizes like water:

where (*am*) represents solvation by  $\text{NH}_3$ .

- (a) Write the ion-product constant expression,  $K_{am}$ .  
 (b) What are the strongest acid and base that can exist in  $\text{NH}_3(l)$ ?  
 (c)  $\text{HNO}_3$  and  $\text{HCOOH}$  are leveled in  $\text{NH}_3(l)$ . Explain with equations.  
 (d) At the boiling point of ammonia ( $-33^\circ\text{C}$ ),  $K_{am} = 5.1 \times 10^{-27}$ . Calculate  $[\text{NH}_4^+]$  at this temperature.  
 (e) Pure sulfuric acid also autoionizes. Write the ion-product constant expression,  $K_{sulf}$ , and find the concentration of the conjugate base at  $20^\circ\text{C}$  ( $K_{sulf} = 2.7 \times 10^{-4}$  at  $20^\circ\text{C}$ ).

**18.160** Thiamine hydrochloride ( $\text{C}_{12}\text{H}_{18}\text{ON}_4\text{SCl}_2$ ) is a water-soluble form of thiamine (vitamin  $\text{B}_1$ ;  $K_a = 3.37 \times 10^{-7}$ ). How many grams of the hydrochloride must be dissolved in 10.00 mL of water to give a pH of 3.50?

**18.161** Tris(hydroxymethyl)aminomethane, known as TRIS or THAM, is a water-soluble base used in synthesizing surfactants and pharmaceuticals, as an emulsifying agent in cosmetics, and in cleaning mixtures for textiles and leather. In biomedical research, solutions of TRIS are used to maintain nearly constant pH for the study of enzymes and other cellular components. Given that the  $pK_b$  is 5.91, calculate the pH of 0.075 M TRIS.

**18.162** When an  $\text{Fe}^{3+}$  salt is dissolved in water, the solution becomes acidic due to formation of  $\text{Fe}(\text{H}_2\text{O})_5\text{OH}^{2+}$  and  $\text{H}_3\text{O}^+$ . The overall process involves both Lewis and Brønsted-Lowry acid-base reactions. Write the equations for the process.

**18.163** What is the pH of a vinegar with 5.0% (w/v) acetic acid in water?

**18.164** The scene below represents a sample of a weak acid HB (*blue and purple*) dissolved in water. Draw a scene that represents the same volume after the solution has been diluted with water.

**18.165** How would you differentiate between a strong and a weak monoprotic acid from the results of the following procedures?  
 (a) Electrical conductivity of an equimolar solution of each acid is measured.  
 (b) Equal molarities of each are tested with pH paper.  
 (c) Zinc metal is added to solutions of equal concentration.

**18.166** The catalytic efficiency of an enzyme, called its *activity*, indicates the rate at which it catalyzes the reaction. Most enzymes have optimum activity over a relatively narrow pH range, which is related to the pH of the local cellular fluid. The pH profiles of three digestive enzymes are shown.

Salivary amylase begins digestion of starches in the mouth and has optimum activity at a pH of 6.8; pepsin begins protein digestion in the stomach and has optimum activity at a pH of 2.0; and trypsin, released in pancreatic juices, continues protein digestion in the small intestine and has optimum activity at a pH of 9.5. Calculate  $[\text{H}_3\text{O}^+]$  in the local cellular fluid for each enzyme.

**18.167** Acetic acid has a  $K_a$  of  $1.8 \times 10^{-5}$ , and ammonia has a  $K_b$  of  $1.8 \times 10^{-5}$ . Find  $[\text{H}_3\text{O}^+]$ ,  $[\text{OH}^-]$ , pH, and pOH for (a) 0.240 M acetic acid and (b) 0.240 M ammonia.

**18.168** The uses of sodium phosphate include clarifying crude sugar, manufacturing paper, removing boiler scale, and washing concrete. What is the pH of a solution containing 33 g of  $\text{Na}_3\text{PO}_4$  per liter? What is  $[\text{OH}^-]$  of this solution?

**18.169** The Group 5A(15) hydrides react with boron trihalides in a reversible Lewis acid-base reaction. When 0.15 mol of  $\text{PH}_3\text{BCl}_3(s)$  is introduced into a 3.0-L container at a certain temperature,  $8.4 \times 10^{-3}$  mol of  $\text{PH}_3$  is present at equilibrium:

- (a) Find  $K_c$  for the reaction at this temperature.  
 (b) Draw a Lewis structure for the reactant.

**18.170** A 1.000 m solution of chloroacetic acid ( $\text{ClCH}_2\text{COOH}$ ) freezes at  $-1.93^\circ\text{C}$ . Find the  $K_a$  of chloroacetic acid. (Assume that the molarities equal the molalities.)

**18.171** Sodium stearate ( $\text{C}_{17}\text{H}_{35}\text{COONa}$ ) is a major component of bar soap. The  $K_a$  of the stearic acid is  $1.3 \times 10^{-5}$ . What is the pH of 10.0 mL of a solution containing 0.42 g of sodium stearate?

**18.172** Calcium propionate [ $\text{Ca}(\text{CH}_3\text{CH}_2\text{COO})_2$ ; calcium propionate] is a mold inhibitor used in food, tobacco, and pharmaceuticals. (a) Use balanced equations to show whether aqueous calcium propionate is acidic, basic, or neutral. (b) Use Appendix C to find the resulting pH when 8.75 g of  $\text{Ca}(\text{CH}_3\text{CH}_2\text{COO})_2$  dissolves in enough water to give 0.500 L of solution.

**18.173** A site in Pennsylvania receives a total annual deposition of 2.688 g/m<sup>2</sup> of sulfate from fertilizer and acid rain. The mass ratio of ammonium sulfate/ammonium bisulfate/sulfuric acid is 3.0/5.5/1.0. (a) How much acid, expressed as kilograms (kg) of sulfuric acid, is deposited over an area of 10. km<sup>2</sup>? (b) How many pounds of  $\text{CaCO}_3$  are needed to neutralize this acid? (c) If 10. km<sup>2</sup> is the area of an unpolluted lake 3 m deep and there is no loss of acid, what pH will the lake water attain by the end of the year? (Assume constant volume.)

**18.174** (a) If  $K_w = 1.139 \times 10^{-15}$  at  $0^\circ\text{C}$  and  $5.474 \times 10^{-14}$  at  $50^\circ\text{C}$ , find  $[\text{H}_3\text{O}^+]$  and pH of water at  $0^\circ\text{C}$  and  $50^\circ\text{C}$ .

(b) The autoionization constant for heavy water (deuterium oxide,  $\text{D}_2\text{O}$ ) is  $3.64 \times 10^{-16}$  at  $0^\circ\text{C}$  and  $7.89 \times 10^{-15}$  at  $50^\circ\text{C}$ . Find  $[\text{D}_3\text{O}^+]$  and pD of heavy water at  $0^\circ\text{C}$  and  $50^\circ\text{C}$ .

(c) Suggest a reason for these differences.

**18.175** HX ( $\mathcal{M} = 150.$  g/mol) and HY ( $\mathcal{M} = 50.0$  g/mol) are weak acids. A solution of 12.0 g/L of HX has the same pH as one containing 6.00 g/L of HY. Which is the stronger acid? Why?

**18.176** The beakers on the facing page depict the aqueous dissociations of weak acids HA (*blue and green*) and HB (*blue and yellow*); solvent molecules are omitted for clarity. If the HA solution is 0.50 L, and the HB solution is 0.25 L, and each particle represents 0.010 mol, find the  $K_a$  of each acid. Which acid, if either, is stronger?

**18.177** In his acid-base studies, Arrhenius discovered an important fact involving reactions like the following:

(a) Complete the reactions and use the data for the individual ions in Appendix B to calculate each  $\Delta H_{\text{rxn}}^\circ$ .

(b) Explain your results and use them to predict  $\Delta H_{\text{rxn}}^\circ$  for

**18.178** Putrescine [ $\text{NH}_2(\text{CH}_2)_4\text{NH}_2$ ], found in rotting animal tissue, is now known to be in all cells and essential for normal and abnormal (cancerous) growth. It also plays a key role in the formation of GABA, a neurotransmitter. A 0.10 M aqueous solution of putrescine has  $[\text{OH}^-] = 2.1 \times 10^{-3}$ . What is the  $K_b$ ?

**18.179** The molecular scene depicts the relative concentrations of  $\text{H}_3\text{O}^+$  (purple) and  $\text{OH}^-$  (green) in an aqueous solution at 25°C. (Counter ions and solvent molecules are omitted for clarity.) (a) Calculate the pH. (b) How many  $\text{H}_3\text{O}^+$  ions would you have to draw for every  $\text{OH}^-$  ion to depict a solution of pH 4?

**18.180** Polymers are not very soluble in water, but their solubility increases if they have charged groups. (a) Casein, a milk protein, contains many  $-\text{COO}^-$  groups on its side chains. How does the solubility of casein vary with pH? (b) Histones are proteins essential to the function of DNA. They are weakly basic due to the presence of side chains with  $-\text{NH}_2$  and  $=\text{NH}$  groups. How does the solubility of a histone vary with pH?

**18.181** Hemoglobin (Hb) transports oxygen in the blood:

In blood,  $[\text{H}_3\text{O}^+]$  is held nearly constant at  $4 \times 10^{-8}$  M.

(a) How does the equilibrium position change in the lungs?

(b) How does it change in  $\text{O}_2$ -deficient cells?

(c) Excessive vomiting may lead to metabolic *alkalosis*, in which  $[\text{H}_3\text{O}^+]$  in blood *decreases*. How does this condition affect the ability of Hb to transport  $\text{O}_2$ ?

(d) Diabetes mellitus may lead to metabolic *acidosis*, in which  $[\text{H}_3\text{O}^+]$  in blood *increases*. How does this condition affect the ability of Hb to transport  $\text{O}_2$ ?

**18.182** Nitrogen is discharged from wastewater treatment facilities into rivers and streams, usually as  $\text{NH}_3$  and  $\text{NH}_4^+$ :

One strategy for removing nitrogen is to raise the pH and “strip” the  $\text{NH}_3$  from solution by bubbling air through the water. (a) At pH 7.00, what fraction of the total nitrogen in solution is  $\text{NH}_3$ , defined as  $[\text{NH}_3]/([\text{NH}_3] + [\text{NH}_4^+])$ ? (b) What is the fraction at pH 10.00? (c) Explain the basis of ammonia stripping.

**18.183** A solution of propanoic acid ( $\text{CH}_3\text{CH}_2\text{COOH}$ ), made by dissolving 7.500 g in sufficient water to make 100.0 mL, has a freezing point of  $-1.890^\circ\text{C}$ .

(a) Calculate the molarity of the solution.

(b) Calculate the molarity of the propanoate ion. (Assume the molarity of the solution equals the molality.)

(c) Calculate the percent dissociation of propanoic acid.

**18.184** The antimalarial properties of quinine ( $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2$ ) saved thousands of lives during construction of the Panama Canal. This substance is a classic example of the medicinal wealth that tropical forests hold. Both N atoms are basic, but the N (colored) of the 3° amine group is far more basic ( $\text{p}K_b = 5.1$ ) than the N within the aromatic ring system ( $\text{p}K_b = 9.7$ ).

(a) A saturated solution of quinine in water is only  $1.6 \times 10^{-3}$  M. What is the pH of this solution?

(b) Show that the aromatic N contributes negligibly to the pH of the solution.

(c) Because of its low solubility, quinine is given as the salt quinine hydrochloride ( $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2 \cdot \text{HCl}$ ), which is 120 times more soluble than quinine. What is the pH of 0.33 M quinine hydrochloride?

(d) An antimalarial concentration in water is 1.5% quinine hydrochloride by mass ( $d = 1.0$  g/mL). What is the pH?

**18.185** Drinking water is often disinfected with  $\text{Cl}_2$ , which hydrolyzes to form  $\text{HClO}$ , a weak acid but powerful disinfectant:

The fraction of  $\text{HClO}$  in solution is defined as

$$\frac{[\text{HClO}]}{[\text{HClO}] + [\text{ClO}^-]}$$

(a) What is the fraction of  $\text{HClO}$  at pH 7.00 ( $K_a$  of  $\text{HClO} = 2.9 \times 10^{-8}$ )?

(b) What is the fraction at pH 10.00?

**18.186** The following scenes represent three weak acids HA (where A = X, Y, or Z) dissolved in water ( $\text{H}_2\text{O}$  is not shown):

(a) Rank the acids in order of increasing  $K_a$ . (b) Rank the acids in order of increasing  $\text{p}K_a$ . (c) Rank the conjugate bases in order of increasing  $\text{p}K_b$ . (d) What is the percent dissociation of HX? (e) If equimolar amounts of the sodium salts of the acids ( $\text{NaX}$ ,  $\text{NaY}$ , and  $\text{NaZ}$ ) were dissolved in water, which solution would have the highest pOH? The lowest pH?

## Concepts and Skills to Review Before You Study This Chapter

- › solubility rules for ionic compounds (Section 4.3)
- › equilibrium nature of a saturated solution (Section 13.4)
- › effect of concentration on equilibrium position (Section 17.6)
- › conjugate acid-base pairs (Section 18.3)
- › calculations for weak-acid and weak-base equilibria (Sections 18.4 and 18.6)
- › acid-base properties of salt solutions (Section 18.7)
- › Lewis acids and bases (Section 18.9)

Continuing our exploration of the universal nature of equilibrium, we now examine aqueous ionic systems. Acid-base and carbonate solubility equilibria are responsible for limestone caves and formations such as those found at Mammoth Hot Springs in Yellowstone National Park (*see photo*). Organisms survive by maintaining cellular pH within narrow limits through complex carbonate and phosphate equilibria. In soils, equilibria involving clays control the availability of ionic nutrients for plants. In industrial settings, the principles of equilibrium govern the softening of water and the purification of products by precipitation of unwanted ions. And they even explain how the weak acids in wine and vinegar influence the delicate taste of a fine sauce.

**IN THIS CHAPTER . . .** We define and quantify three aqueous ionic equilibrium systems—acid-base buffers, slightly soluble salts, and complex ions.

- › We introduce the common-ion effect to explain how buffers work, and see why buffers are important and how to prepare them.
- › We describe several types of acid-base titrations and explore the role buffers play in them.
- › We see that slightly soluble salts have their own equilibrium constant and learn how a common ion and pH influence the solubilities of these compounds.
- › We use concepts of aqueous ionic equilibria to understand how a cave forms.
- › We investigate how complex ions form and change from one type to another.

## 19.1 EQUILIBRIA OF ACID-BASE BUFFERS

Why do some lakes become acidic when showered by acid rain, while others remain unaffected? How does blood maintain a constant pH in contact with countless cellular acid-base reactions? How can a chemist sustain a nearly constant  $[\text{H}_3\text{O}^+]$  in reactions that consume or produce  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$ ? The answer in each case depends on the action of a buffer, and in this section we discuss how buffers work and how to prepare them.

### What a Buffer Is and How It Works: The Common-Ion Effect

In everyday language, a *buffer* is something that lessens the impact of an external force. An **acid-base buffer** is a solution that *lessens the impact on its pH of the addition of acid or base*. Add a small amount of  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$  to an *unbuffered* solution, and the pH changes by several units; thus,  $[\text{H}_3\text{O}^+]$  changes by *several orders of magnitude* (Figure 19.1).

**Figure 19.1** The effect of adding acid or base to an unbuffered solution. **A**, A 100-mL sample of dilute HCl is adjusted to pH 5.00 (*left*). **B**, Adding 1 mL of strong acid (*left*) or of strong base (*right*) changes the pH by several units.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

**Figure 19.2** The effect of adding acid or base to a buffered solution. **A**, A 100-mL sample of an acetate buffer, which was made by mixing 1 M  $\text{CH}_3\text{COOH}$  with 1 M  $\text{CH}_3\text{COONa}$ , is adjusted to pH 5.00. **B**, Adding 1 mL of strong acid (left) or of strong base (right) changes the pH negligibly. Source: © McGraw-Hill Education/Stephen Frisch, photographer

The same addition of strong acid or strong base to a buffered solution causes only a minor change in pH (Figure 19.2). To withstand these additions, a buffer must have an acidic component that reacts with the added  $\text{OH}^-$  and a basic component that reacts with the added  $\text{H}_3\text{O}^+$ . However, these components can't be any acid and base because they would neutralize each other.

- Most often, the components of a buffer are a conjugate acid-base pair (weak acid and conjugate base or weak base and conjugate acid).

The buffer in Figure 19.2, for example, is a mixture of acetic acid ( $\text{CH}_3\text{COOH}$ ) and acetate ion ( $\text{CH}_3\text{COO}^-$ ).

**Presence of a Common Ion** Buffers work through the **common-ion effect**. When you dissolve acetic acid in water, the acid dissociates slightly:

What happens if you now introduce acetate ion by adding the soluble salt sodium acetate? First, we need to recognize that, as a strong electrolyte, sodium acetate dissociates completely in water:

The sodium ion does not interact with water (Section 18.7) and thus is a spectator ion. From Le Châtelier's principle (Section 17.6), we know that adding  $\text{CH}_3\text{COO}^-$  ion will shift the equilibrium position to the left; thus,  $[\text{H}_3\text{O}^+]$  decreases, in effect lowering the extent of acid dissociation:

We get the same result when we add acetic acid to a sodium acetate solution instead of water. The acetate ion already present suppresses the acid from dissociating as much as it does in water, thus keeping the  $[\text{H}_3\text{O}^+]$  lower (and pH higher). In either case, the effect is less acid dissociation. Acetate ion is called *the common ion* because it is "common" to both the acetic acid and sodium acetate solutions. *The common-ion effect occurs when a given ion is added to an equilibrium mixture that already contains that ion, and the position of equilibrium shifts away from forming it.*

Table 19.1 shows that the percent dissociation (and the  $[\text{H}_3\text{O}^+]$ ) of an acetic acid solution decreases as the concentration of acetate ion (supplied by dissolving sodium acetate) increases. Thus, the *common ion*,  $\text{A}^-$ , *suppresses the dissociation of HA*, which makes the solution less acidic (higher pH).

Table 19.1

The Effect of Added Acetate Ion on the Dissociation of Acetic Acid

$[\text{CH}_3\text{COOH}]_{\text{init}}$	$[\text{CH}_3\text{COO}^-]_{\text{added}}$	% Dissociation*	$\text{H}_3\text{O}^+$	pH
0.10	0.00	1.3	$1.3 \times 10^{-3}$	2.89
0.10	0.050	0.036	$3.6 \times 10^{-5}$	4.44
0.10	0.10	0.018	$1.8 \times 10^{-5}$	4.74
0.10	0.15	0.012	$1.2 \times 10^{-5}$	4.92

$$*\% \text{ Dissociation} = \frac{[\text{CH}_3\text{COOH}]_{\text{dissoc}}}{[\text{CH}_3\text{COOH}]_{\text{init}}} \times 100$$

**Relative Concentrations of Buffer Components** A buffer works because a *large amount of the acidic component (HA) of the buffer consumes small amounts of added  $\text{OH}^-$  and a large amount of the basic component ( $\text{A}^-$ ) consumes small amounts of added  $\text{H}_3\text{O}^+$* . Consider what happens in a solution containing high  $[\text{CH}_3\text{COOH}]$  and high  $[\text{CH}_3\text{COO}^-]$  when we add small amounts of strong acid or base. The equilibrium expression for HA dissociation is

$$K_a = \frac{[\text{CH}_3\text{COO}^-][\text{H}_3\text{O}^+]}{[\text{CH}_3\text{COOH}]}$$

Solving for  $[\text{H}_3\text{O}^+]$  gives

$$[\text{H}_3\text{O}^+] = K_a \times \frac{[\text{CH}_3\text{COOH}]}{[\text{CH}_3\text{COO}^-]}$$

Since  $K_a$  is constant, *the  $[\text{H}_3\text{O}^+]$  of the solution depends on the buffer-component concentration ratio,  $\frac{[\text{CH}_3\text{COOH}]}{[\text{CH}_3\text{COO}^-]}$ .*

- If the ratio  $[\text{HA}]/[\text{A}^-]$  goes up (more acid and less conjugate base), then  $[\text{H}_3\text{O}^+]$  goes up.
- If the ratio  $[\text{HA}]/[\text{A}^-]$  goes down (less acid and more conjugate base), then  $[\text{H}_3\text{O}^+]$  goes down.

Let's track this ratio as we add strong acid or strong base to a buffer in which  $[\text{HA}] = [\text{A}^-]$  (Figure 19.3, *middle*):

1. **Strong acid.** When we add a small amount of strong acid, the  $\text{H}_3\text{O}^+$  ions react with an *equal (stoichiometric) amount* of acetate ion, the base component in the buffer, to form more acetic acid:

As a result,  $[\text{CH}_3\text{COO}^-]$  goes down by that small amount and  $[\text{CH}_3\text{COOH}]$  goes up by that amount, which increases the buffer-component concentration ratio (Figure 19.3, *left*). The  $[\text{H}_3\text{O}^+]$  increases *very* slightly.

2. **Strong base.** The addition of a small amount of strong base produces the opposite result. The  $\text{OH}^-$  ions react with an *equal (stoichiometric) amount* of  $\text{CH}_3\text{COOH}$ , the acid component in the buffer, to form that much more  $\text{CH}_3\text{COO}^-$  (Figure 19.3, *right*):

This time, the buffer-component concentration ratio decreases, which decreases  $[\text{H}_3\text{O}^+]$  *very* slightly.

**Figure 19.3** How a buffer works. The relative concentrations of the buffer components, acetic acid ( $\text{CH}_3\text{COOH}$ , red) and acetate ion ( $\text{CH}_3\text{COO}^-$ , blue) are indicated by the heights of the bars.

Thus, the buffer components consume *nearly all* the added  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$ . To reiterate, as long as the amount of added  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$  is small compared with the amounts of the buffer components, *the conversion of one component into the other produces a small change in the buffer-component concentration ratio and, consequently, a small change in  $[\text{H}_3\text{O}^+]$  and in pH.* Sample Problem 19.1 demonstrates how small these pH changes typically are. Note that the latter two parts of the problem combine a stoichiometry portion, like the problems in Chapter 4, and a weak-acid dissociation portion, like those in Chapter 18.

**SAMPLE PROBLEM 19.1**
**Calculating the Effect of Added  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$  on Buffer pH**

**Problem** Calculate the pH: (a) of a buffer solution consisting of 0.50 M HClO ( $K_a = 2.9 \times 10^{-8}$ ) and 0.60 M NaClO; (b) after adding 0.020 mol of solid NaOH to 1.0 L of the buffer solution in part (a); (c) after adding 30.0 mL of 1.5 M HCl to 0.50 L of the buffer solution in part (a). [In part (b), assume that the addition of NaOH causes negligible volume change.]

**Plan** For each part, we know, or can find,  $[\text{HClO}]_{\text{init}}$  and  $[\text{ClO}^-]_{\text{init}}$ . We know the  $K_a$  of HClO ( $2.9 \times 10^{-8}$ ) and need to find  $[\text{H}_3\text{O}^+]$  at equilibrium and convert it to pH. (a) We use the given concentrations of buffer components (0.50 M HClO and 0.60 M  $\text{ClO}^-$ ) as the initial values. As in earlier problems, we assume that  $x$ , the  $[\text{HClO}]$  that dissociates, which equals  $[\text{H}_3\text{O}^+]$ , is so small relative to  $[\text{HClO}]_{\text{init}}$  that it can be neglected. We set up a reaction table, solve for  $x$ , and check the assumption. (b) and (c) We assume that the added  $\text{OH}^-$  or  $\text{H}_3\text{O}^+$  reacts completely with the buffer components to yield new  $[\text{HClO}]_{\text{init}}$  and  $[\text{ClO}^-]_{\text{init}}$ , and then the acid dissociates to an unknown extent. We set up two reaction tables. The first summarizes the stoichiometry of adding strong base or acid. The second summarizes the dissociation of the new  $[\text{HClO}]_{\text{init}}$ , and we proceed as in part (a) to find the new  $[\text{H}_3\text{O}^+]$ . Since there is a volume change due to the added HCl in part (c), we must calculate the new initial concentrations of the buffer components.

**Solution** (a) The original pH:  $[\text{H}_3\text{O}^+]$  in the original buffer. Setting up a reaction table with  $x = [\text{HClO}]_{\text{dissoc}} = [\text{H}_3\text{O}^+]$  (as in Chapter 18, we assume that  $[\text{H}_3\text{O}^+]$  from  $\text{H}_2\text{O}$  is negligible and disregard it):

Concentration (M)	HClO(aq)	+ H <sub>2</sub> O(l)	⇌	ClO <sup>-</sup> (aq)	+ H <sub>3</sub> O <sup>+</sup> (aq)
Initial	0.50	—		0.60	0
Change	-x	—		+x	+x
Equilibrium	0.50 - x	—		0.60 + x	x

Making the assumption and finding the equilibrium  $[\text{HClO}]$  and  $[\text{ClO}^-]$ : With  $K_a$  small,  $x$  is small, so we assume

$$[\text{HClO}] = 0.50 \text{ M} - x \approx 0.50 \text{ M} \quad \text{and} \quad [\text{ClO}^-] = 0.60 \text{ M} + x \approx 0.60 \text{ M}$$

Solving for  $x$  ( $[\text{H}_3\text{O}^+]$  at equilibrium):

$$x = [\text{H}_3\text{O}^+] = K_a \times \frac{[\text{HClO}]}{[\text{ClO}^-]} \approx (2.9 \times 10^{-8}) \times \frac{0.50}{0.60} = 2.4 \times 10^{-8} \text{ M}$$

Checking the assumption:

$$\frac{2.4 \times 10^{-8} \text{ M}}{0.50 \text{ M}} \times 100 = 4.8 \times 10^{-6} \% < 5\%$$

The assumption is justified, and we will use the same assumption in parts (b) and (c). Also, according to the other criterion (see Sample Problem 18.8),

$$\frac{[\text{HA}]_{\text{init}}}{K_a} = \frac{0.50}{2.9 \times 10^{-8}} = 1.7 \times 10^7 > 400$$

Calculating pH:

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log (2.4 \times 10^{-8}) = 7.62$$

(b) The pH after adding base (0.020 mol of NaOH to 1.0 L of buffer). Finding  $[\text{OH}^-]_{\text{added}}$ :

$$[\text{OH}^-]_{\text{added}} = \frac{0.020 \text{ mol OH}^-}{1.0 \text{ L soln}} = 0.020 \text{ M OH}^-$$

Setting up a reaction table for the *stoichiometry* of adding  $\text{OH}^-$  to  $\text{HClO}$  (notice that the reaction between weak acid and strong base goes to completion):

Concentration (M)	$\text{HClO(aq)}$	+	$\text{OH}^- \text{(aq)}$	$\longrightarrow$	$\text{ClO}^- \text{(aq)}$	+	$\text{H}_2\text{O(l)}$
Initial	0.50		0.020		0.60		—
Change	-0.020		-0.020		+0.020		—
Final	0.48		0		0.62		—

Setting up a reaction table for the *acid dissociation*, using these new initial concentrations. As in part (a),  $x = [\text{HClO}]_{\text{dissoc}} = [\text{H}_3\text{O}^+]$ :

Concentration (M)	$\text{HClO(aq)}$	+	$\text{H}_2\text{O(l)}$	$\rightleftharpoons$	$\text{ClO}^- \text{(aq)}$	+	$\text{H}_3\text{O}^+ \text{(aq)}$
Initial	0.48		—		0.62		0
Change	-x		—		+x		+x
Equilibrium	$0.48 - x$		—		$0.62 + x$		x

Making the assumption that  $x$  is small, and solving for  $x$ :

$$[\text{HClO}] = 0.48 \text{ M} - x \approx 0.48 \text{ M} \quad \text{and} \quad [\text{ClO}^-] = 0.62 \text{ M} + x \approx 0.62 \text{ M}$$

$$x = [\text{H}_3\text{O}^+] = K_a \times \frac{[\text{HClO}]}{[\text{ClO}^-]} \approx (2.9 \times 10^{-8}) \times \frac{0.48}{0.62} = 2.2 \times 10^{-8} \text{ M}$$

Calculating the pH:

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log (2.2 \times 10^{-8}) = 7.66$$

The addition of strong base increased the concentration of the basic buffer component at the expense of the acidic buffer component. Note especially that the pH *increased only slightly*, from 7.62 to 7.66.

(c) The pH after adding acid (30.0 mL of 1.5 M HCl to 0.50 L of buffer). Use Equation 4.2 to find the new  $[\text{HClO}]_{\text{init}}$  and  $[\text{ClO}^-]_{\text{init}}$  and  $[\text{H}_3\text{O}^+]_{\text{added}}$  after combining the HCl and buffer solutions; the new volume is 0.50 L + 0.0300 L = 0.53 L:

$$[\text{HClO}]_{\text{init}} = \frac{M_{\text{conc}} \times V_{\text{conc}}}{V_{\text{dil}}} = \frac{0.50 \text{ M} \times 0.50 \text{ L}}{0.53 \text{ L}} = 0.47 \text{ M HClO}$$

$$[\text{ClO}^-]_{\text{init}} = \frac{M_{\text{conc}} \times V_{\text{conc}}}{V_{\text{dil}}} = \frac{0.60 \text{ M} \times 0.50 \text{ L}}{0.53 \text{ L}} = 0.57 \text{ M ClO}^-$$

$$[\text{H}_3\text{O}^+]_{\text{added}} = \frac{M_{\text{conc}} \times V_{\text{conc}}}{V_{\text{dil}}} = \frac{1.5 \text{ M} \times 0.0300 \text{ L}}{0.53 \text{ L}} = 0.085 \text{ M H}_3\text{O}^+$$

Now we proceed as in part (b), by first setting up a reaction table for the *stoichiometry* of adding  $\text{H}_3\text{O}^+$  to  $\text{ClO}^-$  (notice that the reaction between strong acid and weak base goes to completion):

Concentration (M)	$\text{ClO}^- \text{(aq)}$	+	$\text{H}_3\text{O}^+ \text{(aq)}$	$\longrightarrow$	$\text{HClO(aq)}$	+	$\text{H}_2\text{O(l)}$
Initial	0.57		0.085		0.47		—
Change	-0.085		-0.085		+0.085		—
Final	0.48		0		0.56		—

The reaction table for the *acid dissociation*, with  $x = [\text{HClO}]_{\text{dissoc}} = [\text{H}_3\text{O}^+]$  is

Concentration (M)	$\text{HClO(aq)}$	+	$\text{H}_2\text{O(l)}$	$\rightleftharpoons$	$\text{ClO}^- \text{(aq)}$	+	$\text{H}_3\text{O}^+ \text{(aq)}$
Initial	0.56		—		0.48		0
Change	-x		—		+x		+x
Equilibrium	$0.56 - x$		—		$0.48 + x$		x

Making the assumption that  $x$  is small, and solving for  $x$ :

$$[\text{HClO}] = 0.56 \text{ M} - x \approx 0.56 \text{ M} \quad \text{and} \quad [\text{ClO}^-] = 0.48 \text{ M} + x \approx 0.48 \text{ M}$$

$$x = [\text{H}_3\text{O}^+] = K_a \times \frac{[\text{HClO}]}{[\text{ClO}^-]} \approx (2.9 \times 10^{-8}) \times \frac{0.56}{0.48} = 3.4 \times 10^{-8} \text{ M}$$

Calculating the pH:

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log (3.4 \times 10^{-8}) = 7.47$$

The addition of strong acid increased the concentration of the acidic buffer component at the expense of the basic buffer component and *lowered* the pH only slightly, from 7.62 to 7.47.

**Check** The changes in  $[\text{HClO}]$  and  $[\text{ClO}^-]$  occur in opposite directions in parts (b) and (c), which makes sense. The pH increased when base was added in (b) and decreased when acid was added in (c).

**Comment** In part (a), we justified our assumption that  $x$  can be neglected. Therefore, in parts (b) and (c), we could have used the “Final” values from the last line of the stoichiometry reaction tables directly for the ratio of buffer components; that would have allowed us to dispense with a reaction table for the acid dissociation. In subsequent problems in this chapter, we will follow this more straightforward approach.

### FOLLOW-UP PROBLEMS

*Brief Solutions for all Follow-up Problems appear at the end of the chapter.*

**19.1A** Calculate the pH of a buffer consisting of 0.50 M HF and 0.45 M KF (a) before and (b) after addition of 0.40 g of NaOH to 1.0 L of the buffer ( $K_a$  of HF =  $6.8 \times 10^{-4}$ ).

**19.1B** Calculate the pH of a buffer consisting of 0.25 M  $(\text{CH}_3)_2\text{NH}_2\text{Cl}$  and 0.30 M  $(\text{CH}_3)_2\text{NH}$  (a) before and (b) after addition of 50.0 mL of 0.75 M HCl to 1.0 L of the buffer [ $pK_b$  of  $(\text{CH}_3)_2\text{NH} = 3.23$ ].

**SOME SIMILAR PROBLEMS** 19.12–19.21 and 19.28–19.31

Figure 19.4 summarizes the changes in concentrations of buffer components upon addition of strong acid or strong base.

**Figure 19.4** Summary of the effect of added acid or base on the concentrations of buffer components.

## The Henderson-Hasselbalch Equation

For any weak acid, HA, the dissociation equation and  $K_a$  expression are

The key variable that determines  $[\text{H}_3\text{O}^+]$  is the concentration *ratio* of acid species to base species, so, as before, rearranging to isolate  $[\text{H}_3\text{O}^+]$  gives

$$[\text{H}_3\text{O}^+] = K_a \times \frac{[\text{HA}]}{[\text{A}^-]}$$

Taking the negative common (base 10) logarithm of both sides gives

$$\underbrace{-\log [\text{H}_3\text{O}^+]}_{\text{pH}} = \underbrace{-\log K_a}_{\text{p}K_a} - \log \left( \frac{[\text{HA}]}{[\text{A}^-]} \right)$$

which, from definitions, is  $\text{pH} = \text{p}K_a - \log \frac{[\text{HA}]}{[\text{A}^-]}$

Then, because of the nature of logarithms, when we invert the buffer-component concentration ratio, the sign of the logarithm changes, to give  $\text{pH} = \text{p}K_a + \log \left( \frac{[\text{A}^-]}{[\text{HA}]} \right)$ .

Generalizing the previous equation for any conjugate acid-base pair gives the **Henderson-Hasselbalch equation**:

$$\text{pH} = \text{p}K_a + \log \left( \frac{[\text{base}]}{[\text{acid}]} \right) \quad (19.1)$$

This relationship allows us to solve directly for pH instead of having to calculate  $[\text{H}_3\text{O}^+]$  first. For instance, using the Henderson-Hasselbalch equation in part (b) of Sample Problem 19.1, the pH of the buffer after the addition of NaOH is

$$\text{pH} = \text{p}K_a + \log \left( \frac{[\text{ClO}^-]}{[\text{HClO}]} \right) = 7.54 + \log \left( \frac{0.62}{0.48} \right) = 7.65$$

## Buffer Capacity and Buffer Range

Let's consider two key aspects of a buffer—its capacity and the closely related range.

**Buffer Capacity** Buffer capacity is a measure of the “strength” of the buffer, its ability to maintain the pH following addition of strong acid or base. Capacity depends ultimately on component concentrations, both the absolute and relative concentrations:

1. In terms of *absolute* concentrations, *the more concentrated the buffer components, the greater the capacity*. Thus, for a given amount of added  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$ , the pH of a higher capacity buffer changes less than the pH of a lower capacity buffer (Figure 19.5). Note that *buffer pH is independent of buffer capacity*. A buffer made of equal volumes of 1.0 M  $\text{CH}_3\text{COOH}$  and 1.0 M  $\text{CH}_3\text{COO}^-$  has the same pH (4.74) as a buffer made of equal volumes of 0.10 M  $\text{CH}_3\text{COOH}$  and 0.10 M  $\text{CH}_3\text{COO}^-$ , but the more concentrated buffer has a greater capacity.

2. In terms of *relative* concentrations, *the closer the component concentrations are to each other, the greater the capacity*. As a buffer functions, the concentration of one component increases relative to the other. Because the concentration ratio determines the pH, the less the ratio changes, the less the pH changes. Let's compare the percent change in component concentration ratio for a buffer at two different initial ratios:

- Add 0.010 mol of  $\text{OH}^-$  to 1.00 L of buffer with initial concentrations  $[\text{HA}] = [\text{A}^-] = 1.000 \text{ M}$ :  $[\text{A}^-]$  becomes 1.010 M and  $[\text{HA}]$  becomes 0.990 M,

$$\frac{[\text{A}^-]_{\text{final}}}{[\text{HA}]_{\text{final}}} = \frac{1.010 \text{ M}}{0.990 \text{ M}} = 1.02 \quad \frac{[\text{A}^-]_{\text{init}}}{[\text{HA}]_{\text{init}}} = \frac{1.000 \text{ M}}{1.000 \text{ M}} = 1.00$$

$$\text{Percent change} = \frac{1.02 - 1.00}{1.00} \times 100 = 2\%$$

- Add 0.010 mol of  $\text{OH}^-$  to 1.00 L of buffer with initial concentrations  $[\text{HA}] = 0.250 \text{ M}$  and  $[\text{A}^-] = 1.750 \text{ M}$ :  $[\text{A}^-]$  becomes 1.760 M and  $[\text{HA}]$  becomes 0.240 M,

$$\frac{[\text{A}^-]_{\text{final}}}{[\text{HA}]_{\text{final}}} = \frac{1.760 \text{ M}}{0.240 \text{ M}} = 7.33 \quad \frac{[\text{A}^-]_{\text{init}}}{[\text{HA}]_{\text{init}}} = \frac{1.750 \text{ M}}{0.250 \text{ M}} = 7.00$$

$$\text{Percent change} = \frac{7.33 - 7.00}{7.00} \times 100 = 4.7\%$$

Note that the change in the concentration ratio is more than twice as large when the initial component concentrations are different than when they are the same. Thus, *a buffer has the highest capacity when the component concentrations are equal*. In the Henderson-Hasselbalch equation, when  $[\text{A}^-] = [\text{HA}]$ , their ratio is 1, the log term is 0, and so  $\text{pH} = \text{p}K_a$ :

$$\text{pH} = \text{p}K_a + \log \left( \frac{[\text{A}^-]}{[\text{HA}]} \right) = \text{p}K_a + \log 1 = \text{p}K_a + 0 = \text{p}K_a$$

Therefore, *a buffer whose pH is equal to or near the  $\text{p}K_a$  of its acid component has the highest capacity* for a given concentration.

**Buffer Range** Buffer range is the pH range over which the buffer is effective and is also related to the *relative* buffer-component concentrations. The further the concentration ratio is from 1, the less effective the buffer (the lower the buffer capacity). In practice, if the  $[\text{A}^-]/[\text{HA}]$  ratio is greater than 10 or less than 0.1—that is, if one component concentration is more than 10 times the other—buffering action is poor.

### Student Hot Spot

Student data indicate that you may struggle with acid-base buffer calculations. Access the Smartbook to view additional Learning Resources on this topic.

**Figure 19.5** The relation between buffer capacity and pH change. The bars indicate the final pH values, after strong base was added, for four  $\text{CH}_3\text{COOH}/\text{CH}_3\text{COO}^-$  buffers with the same initial pH (4.74) and different component concentrations.

Consider the two extreme concentration ratios for effective buffering:

- For a buffer with  $[A^-]/[HA] = 10$ :  $\text{pH} = \text{p}K_a + \log\left(\frac{10}{1}\right) = \text{p}K_a + 1$ .
- For a buffer with  $[A^-]/[HA] = 0.1$ :  $\text{pH} = \text{p}K_a + \log\left(\frac{1}{10}\right) = \text{p}K_a - 1$ .

Therefore:

- *Buffers have a usable range within  $\pm 1$  pH unit of the  $\text{p}K_a$  of the acid component:*  
 $\text{pH} = \text{p}K_a \pm 1$ .

For example, a buffer consisting of  $\text{CH}_3\text{COOH}$  ( $\text{p}K_a = 4.74$ ) and  $\text{CH}_3\text{COO}^-$  has a usable pH range of  $4.74 \pm 1$ , or from about 3.7 to 5.7.

### SAMPLE PROBLEM 19.2

### Using Molecular Scenes to Examine Buffers

**Problem** The molecular scenes below represent equal-volume samples of four HA/A<sup>-</sup> buffers. (HA is blue and green, and A<sup>-</sup> is green; other ions and water are not shown.)

- Which buffer has the highest pH?
- Which buffer has the greatest capacity?
- Should you add a small amount of concentrated strong acid or strong base to convert sample 1 to sample 2 (assuming no volume change)?

**Plan** The molecular scenes show varying numbers of weak acid molecules (HA) and the conjugate base (A<sup>-</sup>). Because the volumes are equal, the scenes represent molarities as well as numbers. (a) As the pH rises, more HA loses its H<sup>+</sup> and becomes A<sup>-</sup>, so the  $[A^-]/[HA]$  ratio will increase. We examine the scenes to see which has the highest ratio. (b) Buffer capacity depends on buffer-component concentration *and* ratio. We examine the scenes to see which has a high concentration and a ratio close to 1. (c) Adding strong acid converts some A<sup>-</sup> to HA, and adding strong base does the opposite. Comparing the  $[A^-]/[HA]$  ratios in samples 1 and 2 tells which to add.

**Solution** (a) The  $[A^-]/[HA]$  ratios are as follows: For sample 1,  $[A^-]/[HA] = 3/3 = 1$ . Similarly, sample 2 = 0.5; sample 3 = 1; sample 4 = 2. Sample 4 has the highest pH because it has the highest  $[A^-]/[HA]$  ratio.

(b) Samples 1 and 3 have a  $[A^-]/[HA]$  ratio of 1, but sample 3 has the greater capacity because it has a higher concentration.

(c) Sample 2 has a lower  $[A^-]/[HA]$  ratio than sample 1, so you would add strong acid to sample 1 to convert some A<sup>-</sup> to HA.

### FOLLOW-UP PROBLEMS

**19.2A** The molecular scene (*see margin*) shows a sample of an HB/B<sup>-</sup> buffer. (HB is blue and yellow, and B<sup>-</sup> is yellow; other ions and water are not shown.)

- Would you add a small amount of concentrated strong acid or strong base to increase the buffer capacity?
- Assuming no volume change, draw a scene that represents the buffer with the highest possible capacity after the addition in part (a).

**19.2B** The molecular scenes below show three samples of a buffer consisting of HA ( $\text{p}K_a = 4.2$ ) and A<sup>-</sup>. (HA is blue and red, and A<sup>-</sup> is red; other ions and water are not shown.)

- (a) Which buffer has  $\text{pH} > \text{p}K_a$ ?  
 (b) Which buffer can react with the largest amount of added strong base?  
 (c) Is this conjugate acid-base pair suitable for preparing a buffer with a  $\text{pH}$  of 6.1?

**SIMILAR PROBLEMS** 19.10 and 19.11

## Preparing a Buffer

Even though chemical supply-houses offer buffers in a variety of  $\text{pH}$  values and concentrations, you may have to prepare a specific one, for example, in an environmental or biomedical application. Several steps are required to prepare a buffer:

1. *Choose the conjugate acid-base pair.* Deciding on the chemical composition is based to a large extent on the desired  $\text{pH}$ . Suppose that, for a biochemical experiment, you need a buffer whose  $\text{pH}$  is 3.90. Therefore, to maximize the capacity, the  $\text{p}K_a$  of the acid component should be close to 3.90; or  $K_a = 10^{-3.90} = 1.3 \times 10^{-4}$ . A table of  $K_a$  values (see Appendix C) shows that lactic acid ( $\text{p}K_a = 3.86$ ), glycolic acid ( $\text{p}K_a = 3.83$ ), and formic acid ( $\text{p}K_a = 3.74$ ) are possibilities. To avoid substances that are common in biochemical systems, you choose formic acid,  $\text{HCOOH}$ , and formate ion,  $\text{HCOO}^-$ , supplied by a soluble salt, such as sodium formate,  $\text{HCOONa}$ , as the basic component.

2. *Calculate the ratio of buffer component concentrations.* To find the ratio  $[\text{A}^-]/[\text{HA}]$  that gives the desired  $\text{pH}$ , you use Equation 19.1:

$$\begin{aligned} \text{pH} &= \text{p}K_a + \log \left( \frac{[\text{A}^-]}{[\text{HA}]} \right) & \text{or} & & 3.90 &= 3.74 + \log \left( \frac{[\text{HCOO}^-]}{[\text{HCOOH}]} \right) \\ \log \left( \frac{[\text{HCOO}^-]}{[\text{HCOOH}]} \right) &= 0.16 & \text{so} & & \left( \frac{[\text{HCOO}^-]}{[\text{HCOOH}]} \right) &= 10^{0.16} = 1.4 \end{aligned}$$

Thus, for every 1.0 mol of  $\text{HCOOH}$  in a given volume of solution, you need 1.4 mol of  $\text{HCOONa}$ .

3. *Determine the buffer concentration.* For most laboratory-scale applications, concentrations of about 0.5  $M$  are suitable, but the decision is often based on availability of stock solutions. Suppose you have a large stock of 0.40  $M$   $\text{HCOOH}$  and you need approximately 1.0 L of final buffer. First, you find the amount (mol) of sodium formate that will give the needed 1.4/1.0 ratio, and then convert to mass (g):

$$\begin{aligned} \text{Amount (mol) of HCOOH} &= 1.0 \text{ L soln} \times \frac{0.40 \text{ mol HCOOH}}{1.0 \text{ L soln}} = 0.40 \text{ mol HCOOH} \\ \text{Amount (mol) of HCOONa} &= 0.40 \text{ mol HCOOH} \times \frac{1.4 \text{ mol HCOONa}}{1.0 \text{ mol HCOOH}} = 0.56 \text{ mol HCOONa} \\ \text{Mass (g) of HCOONa} &= 0.56 \text{ mol HCOONa} \times \frac{68.01 \text{ g HCOONa}}{1 \text{ mol HCOONa}} = 38 \text{ g HCOONa} \end{aligned}$$

4. *Mix the solution and correct the pH.* You dissolve 38 g of sodium formate in the stock 0.40  $M$   $\text{HCOOH}$  to a total volume of 1.0 L. Because of nonideal behavior (Section 13.6), the buffer may vary slightly from the desired  $\text{pH}$ , so you add strong acid or strong base dropwise, while monitoring the solution with a  $\text{pH}$  meter.

### SAMPLE PROBLEM 19.3

### Preparing a Buffer

**Problem** An environmental chemist needs a carbonate buffer of  $\text{pH}$  10.00 to study the effects of acid rain on limestone-rich soils. How many grams of  $\text{Na}_2\text{CO}_3$  must she add to 1.5 L of 0.20  $M$   $\text{NaHCO}_3$  to make the buffer ( $K_a$  of  $\text{HCO}_3^- = 4.7 \times 10^{-11}$ )?

**Plan** The conjugate pair is  $\text{HCO}_3^-$  (acid) and  $\text{CO}_3^{2-}$  (base), and we know the buffer volume (1.5 L) and the concentration (0.20  $M$ ) of  $\text{HCO}_3^-$ , so we need to find the buffer-component concentration ratio that gives a  $\text{pH}$  of 10.00 and the mass of  $\text{Na}_2\text{CO}_3$  to dissolve. We convert  $K_a$  to  $\text{p}K_a$  and use Equation 19.1 to find the ratio  $[\text{CO}_3^{2-}]/[\text{HCO}_3^-]$  that gives a  $\text{pH}$  of 10.00. Multiplying the given molarity of  $\text{HCO}_3^-$  by the volume of solution gives the amount (mol)

of  $\text{HCO}_3^-$  and the ratio of  $[\text{CO}_3^{2-}]/[\text{HCO}_3^-]$  gives the amount (mol) of  $\text{CO}_3^{2-}$  needed, which we convert to mass (g) of  $\text{Na}_2\text{CO}_3$ .

**Solution** Calculating  $\text{p}K_a$ :

$$\text{p}K_a = -\log K_a = -\log (4.7 \times 10^{-11}) = 10.33$$

Solving for  $[\text{CO}_3^{2-}]/[\text{HCO}_3^-]$ :

$$\begin{aligned} \text{pH} &= \text{p}K_a + \log \left( \frac{[\text{CO}_3^{2-}]}{[\text{HCO}_3^-]} \right) & 10.00 &= 10.33 + \log \left( \frac{[\text{CO}_3^{2-}]}{[\text{HCO}_3^-]} \right) \\ -0.33 &= \log \left( \frac{[\text{CO}_3^{2-}]}{[\text{HCO}_3^-]} \right) & \text{and} & \left( \frac{[\text{CO}_3^{2-}]}{[\text{HCO}_3^-]} \right) = 10^{-0.33} = 0.47 \end{aligned}$$

Calculating the amount (mol) of  $\text{CO}_3^{2-}$  needed for the given volume of solution:

$$\text{Amount (mol) of } \text{HCO}_3^- = 1.5 \text{ L soln} \times \frac{0.20 \text{ mol } \text{HCO}_3^-}{1.0 \text{ L soln}} = 0.30 \text{ mol } \text{HCO}_3^-$$

$$\text{Amount (mol) of } \text{CO}_3^{2-} = 0.30 \text{ mol } \text{HCO}_3^- \times \frac{0.47 \text{ mol } \text{CO}_3^{2-}}{1.0 \text{ mol } \text{HCO}_3^-} = 0.14 \text{ mol } \text{CO}_3^{2-}$$

Calculating the mass (g) of  $\text{Na}_2\text{CO}_3$  needed:

$$\text{Mass (g) of } \text{Na}_2\text{CO}_3 = 0.14 \text{ mol } \text{Na}_2\text{CO}_3 \times \frac{105.99 \text{ g } \text{Na}_2\text{CO}_3}{1 \text{ mol } \text{Na}_2\text{CO}_3} = 15 \text{ g } \text{Na}_2\text{CO}_3$$

The buffer is prepared by dissolving 15 g of  $\text{Na}_2\text{CO}_3$  into about 1.3 L of 0.20 M  $\text{NaHCO}_3$  and adding more 0.20 M  $\text{NaHCO}_3$  to make 1.5 L. Then a pH meter is used to adjust the pH to 10.00 by dropwise addition of concentrated strong acid or base.

**Check** For a useful buffer range, the concentration of the acidic component,  $[\text{HCO}_3^-]$  in this case, must be within a factor of 10 of the concentration of the basic component,  $[\text{CO}_3^{2-}]$ . And we have 0.30 mol of  $\text{HCO}_3^-$ , and 0.14 mol of  $\text{CO}_3^{2-}$ ;  $0.30/0.14 = 2.1$ . Make sure the relative amounts of components are reasonable: we want a pH below the  $\text{p}K_a$  of  $\text{HCO}_3^-$  (10.33), so we want more of the acidic than the basic species.

### FOLLOW-UP PROBLEMS

**19.3A** How would you prepare a benzoic acid/benzoate buffer with a pH of 4.25, starting with 5.0 L of 0.050 M sodium benzoate ( $\text{C}_6\text{H}_5\text{COONa}$ ) solution and adding the acidic component ( $K_a$  of benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ) =  $6.3 \times 10^{-5}$ )?

**19.3B** What is the component concentration ratio,  $[\text{NH}_3]/[\text{NH}_4^+]$  of a buffer that has a pH of 9.18? What mass of  $\text{NH}_4\text{Cl}$  must be added to 750 mL of 0.15 M  $\text{NH}_3$  to prepare the buffer with this pH ( $K_b$  of  $\text{NH}_3$  =  $1.76 \times 10^{-5}$ )?

**SOME SIMILAR PROBLEMS** 19.24–19.27

Another way to prepare a buffer is to form one of the components by *partial neutralization* of the other. For example, you can prepare an  $\text{HCOOH}/\text{HCOO}^-$  buffer by mixing aqueous solutions of  $\text{HCOOH}$  and  $\text{NaOH}$ . As  $\text{OH}^-$  reacts with  $\text{HCOOH}$ , neutralization of some of the  $\text{HCOOH}$  produces the  $\text{HCOO}^-$  needed:

This method is based on the same chemical process that occurs when a weak acid is titrated with a strong base, as you'll see in Section 19.2.

## › Summary of Section 19.1

- › The pH of a buffered solution changes much less than the pH of an unbuffered solution when  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$  is added.
- › A buffer consists of a weak acid and its conjugate base (or a weak base and its conjugate acid). To be effective, the amounts of the components must be *much* greater than the amount of  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$  added.
- › The buffer-component concentration ratio determines the pH; the ratio and the pH are related by the Henderson-Hasselbalch equation.

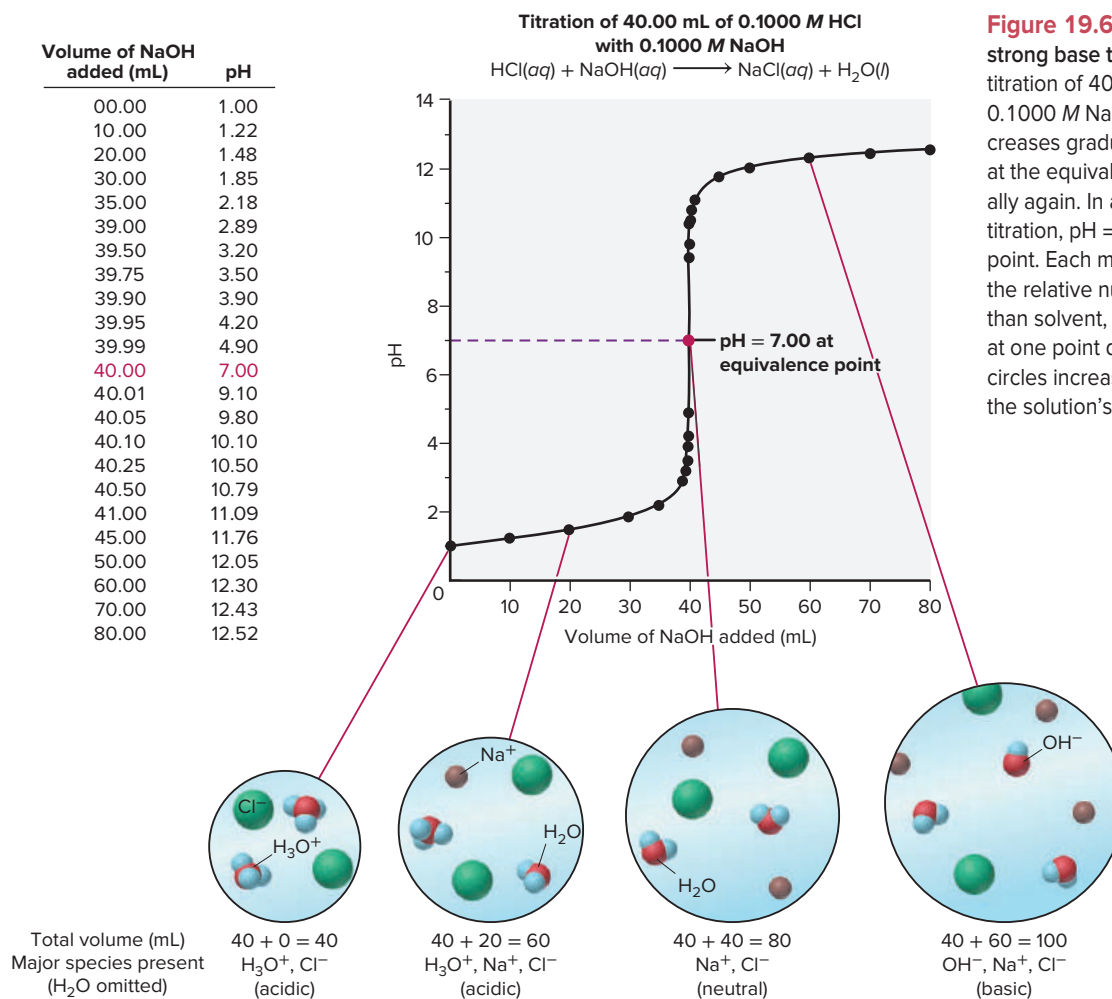

- › When  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$  is added to a buffer, one component reacts to form the other; thus,  $[\text{H}_3\text{O}^+]$  (and pH) changes only slightly.
- › A concentrated (higher capacity) buffer undergoes smaller changes in pH than a dilute buffer. When the buffer pH equals the  $\text{p}K_a$  of the acid component, the buffer has its highest capacity.
- › A buffer has an effective pH range of  $\text{p}K_a \pm 1$  pH unit.
- › To prepare a buffer, choose the conjugate acid-base pair, calculate the ratio of components, determine the buffer concentration, and adjust the final solution to the desired pH.

## 19.2 ACID-BASE TITRATION CURVES

In Chapter 4, we used titrations to quantify acid-base (and redox) reactions. In this section, we focus on the **acid-base titration curve**, a plot of pH vs. volume of titrant added. We discuss curves for strong acid–strong base, weak acid–strong base, weak base–strong acid, and polyprotic acid–strong base titrations. Running a titration is an exercise for the lab, but understanding the role of acid-base indicators and seeing how salt solutions (Section 18.7) and buffers are involved apply key principles of acid-base equilibria.

### Strong Acid–Strong Base Titration Curves

Figure 19.6 shows a typical curve for the titration of a strong acid with a strong base, the data used to construct it, and molecular views of the key species in solution at various points during the titration.

**Figure 19.6** Curve for a strong acid–strong base titration. Data (at left) for the titration of 40.00 mL of 0.1000 M HCl with 0.1000 M NaOH. In the titration, pH increases gradually, then rapidly near and at the equivalence point, and then gradually again. In a strong acid–strong base titration,  $\text{pH} = 7.00$  at the equivalence point. Each molecular-scale view shows the relative numbers of species, other than solvent, in a portion of the solution at one point during the titration. The circles increase in size in proportion to the solution's total volume.

**Features of the Curve** There are three distinct regions of the titration curve, which correspond to three major changes in slope:

1. *The pH starts out low*, reflecting the high  $[\text{H}_3\text{O}^+]$  of the strong acid, and increases slowly as acid is gradually neutralized by the added base.
2. *The pH rises 6 to 8 units very rapidly*. This steep increase begins when the amount (mol) of  $\text{OH}^-$  added nearly equals the amount (mol) of  $\text{H}_3\text{O}^+$  originally present in the acid. One or two more drops of base neutralize the remaining tiny excess of acid and introduce a tiny excess of base.

The **equivalence point** occurs when the *number of moles of added  $\text{OH}^-$  equals the number of moles of  $\text{H}_3\text{O}^+$  originally present*. The solution consists of the anion of the strong acid and the cation of the strong base. Recall from Chapter 18 that these ions do not react with water, so the solution is neutral:  $\text{pH} = 7.00$ .

3. *The pH increases slowly beyond the steep rise as more base is added*.

**Calculating the pH During This Titration** By knowing the chemical species present during the titration, we can calculate the pH at various points along the way:

1. *Initial solution of strong HA*. In Figure 19.6, 40.00 mL of 0.1000 M HCl is titrated with 0.1000 M NaOH. Because a strong acid is completely dissociated,  $[\text{HCl}] = [\text{H}_3\text{O}^+] = 0.1000 \text{ M}$ . Therefore, the initial pH is\*

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log (0.1000) = 1.00$$

2. *Before the equivalence point*. As we start adding base, some acid is neutralized and the volume of solution increases. To find the pH at various points up to the equivalence point, we find the *initial* amount (mol) of  $\text{H}_3\text{O}^+$  and amount (mol) of added  $\text{OH}^-$ ; next, we set up a reaction table and subtract the amount of  $\text{H}_3\text{O}^+$  reacted, which equals the amount (mol) of  $\text{OH}^-$  added ( $\text{OH}^-$  is the limiting reactant), to find the amount (mol) of  $\text{H}_3\text{O}^+$  remaining. Then, we use the *total* volume to calculate  $[\text{H}_3\text{O}^+]$  and convert to pH. For example, after adding 20.00 mL of 0.1000 M NaOH:

- *Find the amount (mol) of  $\text{H}_3\text{O}^+$  remaining*.

$$\text{Initial amount (mol) of } \text{H}_3\text{O}^+ = 0.04000 \text{ L} \times 0.1000 \text{ M} = 0.004000 \text{ mol } \text{H}_3\text{O}^+$$

$$\text{Amount (mol) of } \text{OH}^- \text{ added} = 0.02000 \text{ L} \times 0.1000 \text{ M} = 0.002000 \text{ mol } \text{OH}^-$$

Amount (mol)	$\text{H}_3\text{O}^+(\text{aq})$	+	$\text{OH}^-(\text{aq})$	→	$\text{H}_2\text{O}(\text{l})$
Initial	0.004000		0.002000		—
Change	-0.002000		-0.002000		—
Final	0.002000		0		—

- *Calculate  $[\text{H}_3\text{O}^+]$* . We divide by the *total volume* because one solution dilutes the ions in the other:

$$\begin{aligned} [\text{H}_3\text{O}^+] &= \frac{\text{amount (mol) of } \text{H}_3\text{O}^+ \text{ remaining}}{\text{original volume of acid} + \text{volume of added base}} \\ &= \frac{0.002000 \text{ mol } \text{H}_3\text{O}^+}{0.04000 \text{ L} + 0.02000 \text{ L}} = 0.03333 \text{ M} \quad \text{pH} = -\log (0.03333) = 1.48 \end{aligned}$$

Given the amount of  $\text{OH}^-$  added, we are halfway to the equivalence point; but we are still on the initial slow rise of the curve, so the pH is still very low. Similar calculations give values up to the equivalence point.

3. *At the equivalence point*. After 40.00 mL of 0.1000 M NaOH (0.004000 mol of  $\text{OH}^-$ ) has been added to the initial 0.004000 mol of  $\text{H}_3\text{O}^+$ , the equivalence point is reached. The solution contains only  $\text{Na}^+$  and  $\text{Cl}^-$ , neither of which reacts with water. Because of the autoionization of water, however,

$$[\text{H}_3\text{O}^+] = 1.0 \times 10^{-7} \text{ M} \quad \text{pH} = 7.00$$

\*In acid-base titrations, volumes and concentrations are usually known to four significant figures, but pH is reported to no more than two digits to the right of the decimal point.

4. *After the equivalence point.* From the equivalence point on, the pH calculation is based on the amount (mol) of *excess*  $\text{OH}^-$  present. Find the amount (mol) of added  $\text{OH}^-$  and set up a reaction table with the *original* amount of  $\text{HCl}$ ; subtract the amount of  $\text{OH}^-$  reacted, which equals the amount (mol) of initial  $\text{H}_3\text{O}^+$  ( $\text{H}_3\text{O}^+$  is now the *limiting reactant*), to find the amount (mol) of  $\text{OH}^-$  remaining. Then, we use the *total* volume to calculate  $[\text{OH}^-]$  and convert to pOH and then to pH. For example, after adding 50.00 mL of  $\text{NaOH}$  to the 40.00 mL of  $\text{HCl}$ :

- Find the amount (mol) of  $\text{OH}^-$  remaining.

Total amount (mol) of  $\text{OH}^-$  added =  $0.05000 \text{ L} \times 0.1000 \text{ M} = 0.005000 \text{ mol OH}^-$

Amount (mol)	$\text{H}_3\text{O}^+(\text{aq})$	+	$\text{OH}^-(\text{aq})$	→	$\text{H}_2\text{O}(\text{l})$
Initial	0.004000		0.005000		—
Change	-0.004000		-0.004000		—
Final	0		0.001000		—

- Calculate  $[\text{OH}^-]$ .

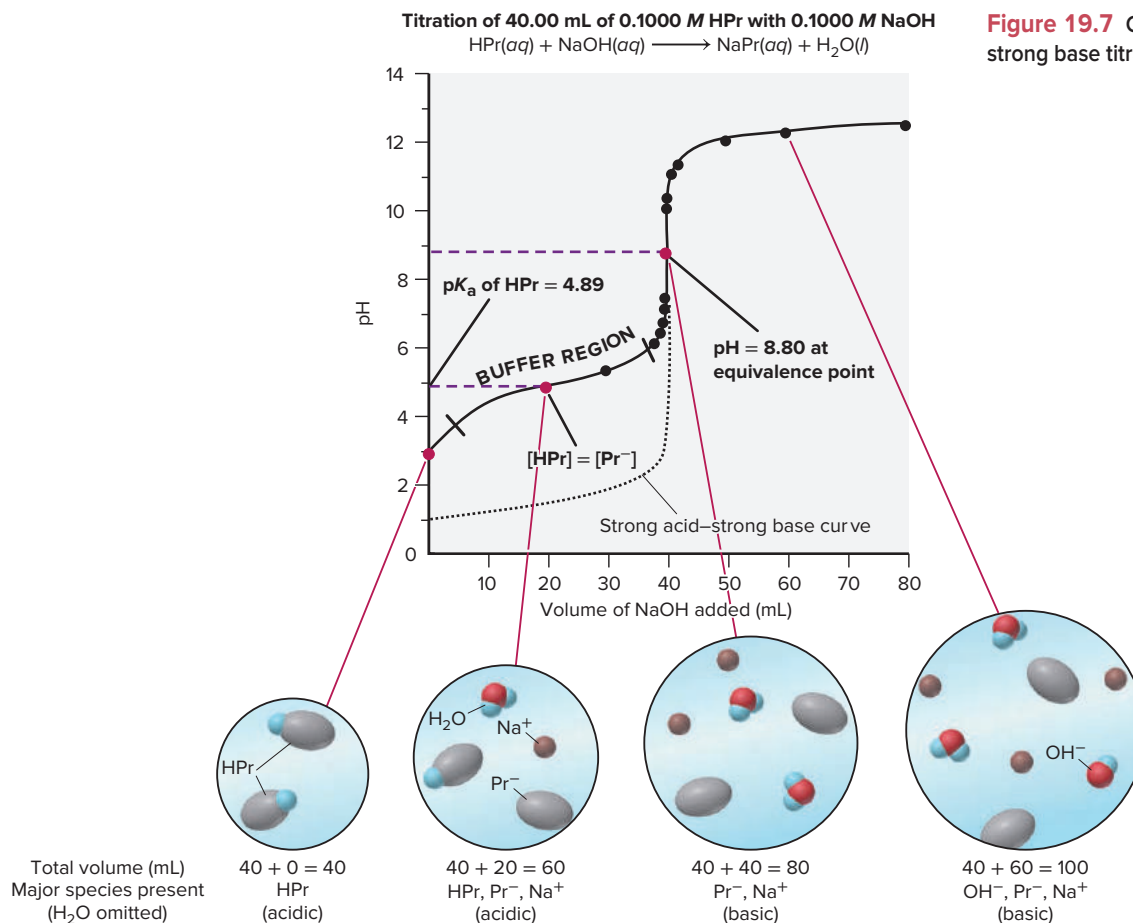

$$[\text{OH}^-] = \frac{\text{amount (mol) of OH}^- \text{ remaining}}{\text{original volume of acid} + \text{volume of added base}}$$

$$= \frac{0.001000 \text{ mol OH}^-}{0.04000 \text{ L} + 0.05000 \text{ L}} = 0.01111 \text{ M} \quad \text{pOH} = -\log(0.01111) = 1.95$$

$$\text{pH} = \text{p}K_w - \text{pOH} = 14.00 - 1.95 = 12.05$$

## Weak Acid–Strong Base Titration Curves

Figure 19.7 shows a curve for the titration of a weak acid with strong base: 40.00 mL of 0.1000 M propanoic acid ( $K_a = 1.3 \times 10^{-5}$ ) titrated with 0.1000 M  $\text{NaOH}$ . (We abbreviate the acid,  $\text{CH}_3\text{CH}_2\text{COOH}$ , as  $\text{HPr}$  and the conjugate base,  $\text{CH}_3\text{CH}_2\text{COO}^-$ , as  $\text{Pr}^-$ .)

**Figure 19.7** Curve for a weak acid–strong base titration.

**Features of the Curve** The dotted portion of the curve in Figure 19.7 corresponds to the bottom half of the strong acid–strong base curve (Figure 19.6). There are four key points to note for the weak acid curve (the first three differ from the points about the strong acid curve):

1. *The initial pH is higher.* Because the weak acid (HPr) dissociates slightly, much less  $\text{H}_3\text{O}^+$  is present than with the strong acid.
2. *The curve rises gradually in the so-called buffer region before the steep rise to the equivalence point.* As HPr reacts with strong base, more  $\text{Pr}^-$  forms, which creates an HPr/ $\text{Pr}^-$  buffer. At the midpoint of the buffer region, half the initial HPr has reacted (that is, half of the  $\text{OH}^-$  needed to reach the equivalence point has been added), so  $[\text{HPr}] = [\text{Pr}^-]$ , or  $[\text{Pr}^-]/[\text{HPr}] = 1$ . Therefore, at this point, *the pH equals the  $\text{p}K_a$ :*

$$\text{pH} = \text{p}K_a + \log \left( \frac{[\text{Pr}^-]}{[\text{HPr}]} \right) = \text{p}K_a + \log 1 = \text{p}K_a + 0 = \text{p}K_a$$

The pH observed at this point, halfway through the titration, is used to estimate the  $\text{p}K_a$  of an unknown acid.

3. *The pH at the equivalence point is above 7.00.* The solution contains the strong-base cation  $\text{Na}^+$ , which does not react with water, and  $\text{Pr}^-$ , the conjugate base of HPr, which, as a weak base, accepts a proton from  $\text{H}_2\text{O}$  and yields  $\text{OH}^-$ .
4. *The pH increases slowly beyond the equivalence point as excess  $\text{OH}^-$  is added.*

**Calculating the pH During This Titration** During the weak acid–strong base titration we must take into account the partial dissociation of the weak acid, the presence of the buffer, and the reaction of the conjugate base with water. Thus, each of four regions of the curve requires its own calculation to find  $[\text{H}_3\text{O}^+]$ :

1. *Initial HA solution.* Before base is added, a weak acid dissociates:

We find  $[\text{H}_3\text{O}^+]$  as in Section 18.4 by setting up a reaction table with  $x = [\text{HPr}]_{\text{dissoc}}$ , assuming  $[\text{H}_3\text{O}^+]$  (and  $[\text{Pr}^-]$ ) =  $[\text{HPr}]_{\text{dissoc}} \ll [\text{HPr}]_{\text{init}}$ , and solving for  $x$ :

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{Pr}^-]}{[\text{HPr}]} \approx \frac{x^2}{[\text{HPr}]_{\text{init}}} \quad \text{therefore,} \quad x = [\text{H}_3\text{O}^+] \approx \sqrt{K_a \times [\text{HPr}]_{\text{init}}}$$

2. *Solution of HA and added base.* As we add NaOH, HPr forms  $\text{Pr}^-$ . Thus, for much of the titration up to the equivalence point, we have an HPr/ $\text{Pr}^-$  buffer. Therefore, we find pH from the Henderson-Hasselbalch equation:

$$\text{pH} = \text{p}K_a + \log \frac{[\text{Pr}^-]}{[\text{HPr}]}$$

Because *volumes cancel in the concentration ratio*, that is,  $[\text{Pr}^-]/[\text{HPr}] = \text{amount (mol) of } \text{Pr}^-/\text{amount (mol) of HPr}$ , we don't need volumes or need to calculate concentrations.

3. *Equivalent amounts of HA and added base.* At the equivalence point, all of the HPr has reacted, so the solution contains  $\text{Pr}^-$ , which reacts with water to form  $\text{OH}^-$ :

This explains why, in a weak acid–strong base titration,  $\text{pH} > 7.00$  at the equivalence point. To calculate  $[\text{H}_3\text{O}^+]$  (see Section 18.6), we first find  $K_b$  of  $\text{Pr}^-$  from  $K_a$  of HPr, set up a reaction table (assume  $[\text{Pr}^-] \gg [\text{Pr}^-]_{\text{reacting}}$ ), and solve for  $[\text{OH}^-]$ . Since we use a single concentration,  $[\text{Pr}^-]$ , to solve for  $[\text{OH}^-]$ , we *do* need the total volume. Then, we convert  $[\text{OH}^-]$  to  $[\text{H}_3\text{O}^+]$ . These two steps are

$$(1) K_b = \frac{[\text{OH}^-][\text{HPr}]}{[\text{Pr}^-]} \approx \frac{x^2}{[\text{Pr}^-]}, \text{ or } x = [\text{OH}^-] \approx \sqrt{K_b \times [\text{Pr}^-]}$$

$$\text{where } K_b = \frac{K_w}{K_a} \quad \text{and} \quad [\text{Pr}^-] = \frac{\text{amount (mol) of HPr}_{\text{init}}}{\text{total volume}}$$

$$(2) [\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]}$$

### Student Hot Spot

Student data indicate that you may struggle with the concept of acid–base titration curves. Access the Smartbook to view additional Learning Resources on this topic.

4. *Solution of excess base.* Beyond the equivalence point, as in the strong acid–strong base titration, we are adding excess  $\text{OH}^-$ ; the very small amount of  $\text{OH}^-$  produced by the reaction of  $\text{Pr}^-$  with water is negligible compared to the amount of  $\text{OH}^-$  from the excess  $\text{NaOH}$ :

$$[\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} \quad \text{where} \quad [\text{OH}^-] = \frac{\text{amount (mol) of excess OH}^-}{\text{total volume}}$$

Sample Problem 19.4 shows the overall approach.

### SAMPLE PROBLEM 19.4

### Finding the pH During a Weak Acid–Strong Base Titration

**Problem** Calculate the pH during the titration of 40.00 mL of 0.1000 *M* propanoic acid (HPr;  $K_a = 1.3 \times 10^{-5}$ ) after each of the following additions of 0.1000 *M* NaOH:

(a) 0.00 mL      (b) 30.00 mL      (c) 40.00 mL      (d) 50.00 mL

**Plan** (a) 0.00 mL: No base has been added yet, so this is a weak-acid dissociation. We calculate the pH as we did in Section 18.4. (b) 30.00 mL: We find the amount (mol) of  $\text{Pr}^-$  and of HPr, and substitute into the Henderson-Hasselbalch equation to solve for pH. (c) 40.00 mL: The amount (mol) of NaOH added equals the initial amount (mol) of HPr, so a solution of  $\text{Na}^+$  and  $\text{Pr}^-$  exists. We calculate the pH as we did in Section 18.6, except that we need *total volume* to find  $[\text{Pr}^-]$ . (d) 50.00 mL: We calculate the amount (mol) of excess  $\text{OH}^-$  in the total volume, convert to  $[\text{H}_3\text{O}^+]$  and then to pH.

**Solution** (a) 0.00 mL of 0.1000 *M* NaOH added. Following the approach used in Sample Problem 18.8 and just described in the text, we obtain

Concentration ( <i>M</i> )	HPr( <i>aq</i> )	+	H <sub>2</sub> O( <i>l</i> )	⇌	H <sub>3</sub> O <sup>+</sup> ( <i>aq</i> )	+	Pr <sup>-</sup> ( <i>aq</i> )
Initial	0.1000		—		0		0
Change	− <i>x</i>		—		+ <i>x</i>		+ <i>x</i>
Equilibrium	0.1000 − <i>x</i>		—		<i>x</i>		<i>x</i>

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{Pr}^-]}{[\text{HPr}]} = 1.3 \times 10^{-5} \approx \frac{(x)(x)}{0.1000}$$

$$[\text{H}_3\text{O}^+] = x \approx \sqrt{K_a \times [\text{HPr}]_{\text{init}}} = \sqrt{(1.3 \times 10^{-5})(0.1000)} = 1.1 \times 10^{-3} \text{ M}$$

$$\text{pH} = 2.96$$

(b) 30.00 mL of 0.1000 *M* NaOH added. Calculating the initial amounts of HPr and  $\text{OH}^-$ :

$$\text{Initial amount (mol) of HPr} = 0.04000 \text{ L} \times 0.1000 \text{ M} = 0.004000 \text{ mol HPr}$$

$$\text{Amount (mol) of NaOH added} = 0.03000 \text{ L} \times 0.1000 \text{ M} = 0.003000 \text{ mol OH}^-$$

For every mole of NaOH, 1 mol of  $\text{Pr}^-$  forms, so we have this stoichiometry reaction table:

Amount (mol)	HPr( <i>aq</i> )	+	OH <sup>-</sup> ( <i>aq</i> )	→	Pr <sup>-</sup> ( <i>aq</i> )	+	H <sub>2</sub> O( <i>l</i> )
Initial	0.004000		0.003000		0		—
Change	−0.003000		−0.003000		+0.003000		—
Final	0.001000		0		0.003000		—

The last line of the table gives the new initial amounts of HPr and  $\text{Pr}^-$  that react to attain a new equilibrium. With *x* very small, we assume that the  $[\text{HPr}]/[\text{Pr}^-]$  ratio at equilibrium is essentially equal to the ratio of these new initial amounts (see Comment in Sample Problem 19.1).

Calculating  $\text{p}K_a$ :

$$\text{p}K_a = -\log K_a = -\log (1.3 \times 10^{-5}) = 4.89$$

Solving for pH using the Henderson-Hasselbalch equation:

$$\text{pH} = \text{p}K_a + \log \frac{[\text{Pr}^-]}{[\text{HPr}]} = 4.89 + \log \frac{0.003000}{0.001000}$$

$$\text{pH} = 5.37$$

(c) 40.00 mL of 0.1000 M NaOH added. Calculating the initial amounts of HPr and OH<sup>-</sup>:

$$\text{Initial amount (mol) of HPr} = 0.04000 \text{ L} \times 0.1000 \text{ M} = 0.004000 \text{ mol HPr}$$

$$\text{Amount (mol) of NaOH added} = 0.04000 \text{ L} \times 0.1000 \text{ M} = 0.004000 \text{ mol OH}^-$$

We have this stoichiometry reaction table:

Amount (mol)	HPr(aq)	+ OH <sup>-</sup> (aq)	→ Pr <sup>-</sup> (aq)	+ H <sub>2</sub> O(l)
Initial	0.004000	0.004000	0	—
Change	0.004000	-0.004000	+0.004000	—
Final	0	0	0.004000	—

Calculating [Pr<sup>-</sup>] after all HPr has reacted:

$$[\text{Pr}^-] = \frac{0.004000 \text{ mol}}{0.04000 \text{ L} + 0.04000 \text{ L}} = 0.05000 \text{ M}$$

Setting up a reaction table for the base dissociation, with  $x = [\text{Pr}^-]_{\text{reacting}} = [\text{OH}^-]$  and assuming  $[\text{Pr}^-]_{\text{reacting}} \ll [\text{Pr}^-]_{\text{init}}$ , calculating  $K_b$ , and solving for  $x$  (see Sample Problem 18.12 for similar steps):

Concentration, M	Pr <sup>-</sup> (aq)	+ H <sub>2</sub> O(l)	⇌ HPr(aq)	+ OH <sup>-</sup>
Initial	0.05000	—	0	0
Change	-x	—	+x	+x
Equilibrium	0.05000 - x	—	x	x

$$K_b = \frac{K_w}{K_a} = \frac{1.0 \times 10^{-14}}{1.3 \times 10^{-5}} = 7.7 \times 10^{-10}$$

$$K_b = \frac{[\text{HPr}][\text{OH}^-]}{[\text{Pr}^-]} = 7.7 \times 10^{-10} \approx \frac{(x)(x)}{0.05000}$$

$$[\text{OH}^-] = x \approx \sqrt{K_b \times [\text{Pr}^-]_{\text{init}}} = \sqrt{(7.7 \times 10^{-10})(0.05000)} = 6.2 \times 10^{-6} \text{ M}$$

$$[\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{6.2 \times 10^{-6}} = 1.6 \times 10^{-9} \text{ M}$$

$$\text{pH} = 8.80$$

(d) 50.00 mL of 0.1000 M NaOH added. Calculating the initial amounts of HPr and OH<sup>-</sup>:

$$\text{Initial amount (mol) of HPr} = 0.04000 \text{ L} \times 0.1000 \text{ M} = 0.004000 \text{ mol HPr}$$

$$\text{Amount (mol) of NaOH added} = 0.05000 \text{ L} \times 0.1000 \text{ M} = 0.005000 \text{ mol OH}^-$$

We have this stoichiometry reaction table:

Amount (mol)	HPr(aq)	+ OH <sup>-</sup> (aq)	→ Pr <sup>-</sup> (aq)	+ H <sub>2</sub> O(l)
Initial	0.004000	0.005000	0	—
Change	-0.004000	-0.004000	+0.004000	—
Final	0	0.001000	0.004000	—

$$[\text{OH}^-] = \frac{\text{amount (mol) of excess OH}^-}{\text{total volume}} = \frac{0.001000 \text{ mol}}{0.04000 \text{ L} + 0.05000 \text{ L}} = 0.01111 \text{ M}$$

$$[\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{0.01111} = 9.0 \times 10^{-13} \text{ M}$$

$$\text{pH} = 12.05$$

**Check** As expected, the pH increases through the four regions of the titration. Be sure to round off and check the arithmetic along the way.

#### FOLLOW-UP PROBLEMS

**19.4A** A chemist titrates 20.00 mL of 0.2000 M HBrO ( $K_a = 2.3 \times 10^{-9}$ ) with 0.1000 M NaOH. What is the pH:

(a) before any base is added?

(b) when  $[\text{HBrO}] = [\text{BrO}^-]$ ?

(c) at the equivalence point?

(d) when the amount (mol) of  $\text{OH}^-$  added is twice the amount of  $\text{HBrO}$  present initially?

(e) Sketch the titration curve, and label the  $\text{p}K_a$  and the equivalence point.

**19.4B** For the titration of 30.00 mL of 0.1000 M benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ;  $K_a = 6.3 \times 10^{-5}$ ) with 0.1500 M NaOH, calculate:

- (a) the initial pH, before the titration begins;  
 (b) the pH after the addition of 12.00 mL of base;  
 (c) the pH at the equivalence point; and  
 (d) the pH after addition of 22.00 mL of base.

**SOME SIMILAR PROBLEMS** 19.51, 19.53(a), and 19.54(a)

### Student Hot Spot

Student data indicate that you may struggle with the calculation of pH during a weak acid-strong base titration. Access the Smartbook to view additional Learning Resources on this topic.

## Weak Base–Strong Acid Titration Curves

The opposite of a weak acid–strong base titration is the titration of a weak base ( $\text{NH}_3$ ) with a strong acid ( $\text{HCl}$ ). This titration curve, shown in Figure 19.8, has the *same shape as the weak acid–strong base curve, but it is inverted*.

Thus, we have the same features as the weak acid–strong base curve, but *the pH decreases* throughout the process:

1. *The initial weak-base solution has a pH well above 7.00* since  $\text{NH}_3$  in water produces  $\text{OH}^-$ :

$[\text{H}_3\text{O}^+]$  can be calculated from the following relationships (see Sample Problem 18.11):

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} \approx \frac{x^2}{[\text{NH}_3]_{\text{init}}} \quad \text{therefore,} \quad x = [\text{OH}^-] \approx \sqrt{K_b \times [\text{NH}_3]_{\text{init}}}$$

$$[\text{H}_3\text{O}^+] \approx \frac{K_w}{[\text{OH}^-]}$$

**Titration of 40.00 mL of 0.1000 M  $\text{NH}_3$  with 0.1000 M  $\text{HCl}$**   
 $\text{NH}_3(\text{aq}) + \text{HCl}(\text{aq}) \longrightarrow \text{NH}_4\text{Cl}(\text{aq})$

**Figure 19.8** Curve for a weak base–strong acid titration.

2. The pH decreases gradually in the buffer region, where significant amounts of  $\text{NH}_3$  and its conjugate acid,  $\text{NH}_4^+$ , are present. At the midpoint of this region, the pH equals the  $pK_a$  of  $\text{NH}_4^+$ :

$$\text{pH} = pK_a + \log \left( \frac{[\text{NH}_3]}{[\text{NH}_4^+]}\right) = pK_a + \log 1 = pK_a + 0 = pK_a$$

3. The curve drops steeply at the equivalence point. All the  $\text{NH}_3$  has reacted with added HCl, and the solution contains only  $\text{NH}_4^+$  and  $\text{Cl}^-$ . Note that the pH at the equivalence point is below 7.00 because  $\text{Cl}^-$  does not react with water and  $\text{NH}_4^+$  is acidic:

The pH at the equivalence point is calculated with this relationship:

$$K_a = \frac{[\text{NH}_3][\text{H}_3\text{O}^+]}{[\text{NH}_4^+]} \approx \frac{x^2}{[\text{NH}_4^+]} \quad \text{therefore, } x = [\text{H}_3\text{O}^+] \approx \sqrt{K_a \times [\text{NH}_4^+]}$$

4. The pH decreases slowly beyond the equivalence point as excess  $\text{H}_3\text{O}^+$  is added.

$$[\text{H}_3\text{O}^+] = \frac{\text{amount (mol) of excess } \text{H}_3\text{O}^+}{\text{total volume}}$$

## Monitoring pH with Acid-Base Indicators

An acid-base indicator is a weak organic acid (denoted as HIn) whose color (A) differs from the color (B) of its conjugate base ( $\text{In}^-$ ) because the two species have slightly different structures. For example, the acid form of the very commonly used indicator phenolphthalein is colorless, while the conjugate base form is pink:

The color change between HIn and  $\text{In}^-$  occurs over a specific, narrow pH range. Typically, either HIn or  $\text{In}^-$  or both are highly colored, so only a tiny amount of indicator is needed, far too little to affect the pH during the titration.

**Color Changes of Acid-Base Indicators** Figure 19.9 shows the color change(s) and pH range(s) of some acid-base indicators. To select an indicator, you must know the approximate pH of the titration end point, which means you know the ionic species present. Because the indicator is a weak acid, the  $[\text{In}^-]/[\text{HIn}]$  ratio is governed by the  $[\text{H}_3\text{O}^+]$  of the solution:

During an acid-base titration,  $[\text{H}_3\text{O}^+]$  changes and the indicator equilibrium reaction will shift. Thus, the  $[\text{H}_3\text{O}^+]$  (or pH) of the solution being titrated determines the  $[\text{In}^-]/[\text{HIn}]$  ratio, which determines the color of the indicator in the solution:

- At lower pH,  $[\text{H}_3\text{O}^+]$  is higher and the indicator equilibrium lies to the left, so  $[\text{HIn}] \gg [\text{In}^-]$ . The acid color of the indicator is seen when there is at least ten times more HIn than  $\text{In}^-$  or when  $[\text{In}^-]/[\text{HIn}] \leq 1/10$ .
- As pH increases,  $[\text{H}_3\text{O}^+]$  decreases and, according to Le Châtelier's principle, the indicator equilibrium shifts to the right, decreasing  $[\text{HIn}]$  and increasing  $[\text{In}^-]$ . We see a color that is intermediate between the acid and base colors of the indicator when  $[\text{In}^-]/[\text{HIn}] \approx 1$ .
- At even higher pH,  $[\text{H}_3\text{O}^+]$  decreases until the indicator equilibrium is shifted far enough to the right that  $[\text{In}^-] \gg [\text{HIn}]$ . We see the base color of the indicator when  $[\text{In}^-]/[\text{HIn}] \geq 10/1$ .

**Figure 19.9** Colors and approximate pH ranges of some common acid-base indicators.

The Henderson-Hasselbalch equation relates the ratio of  $[\text{In}^-]/[\text{HIn}]$  to the  $\text{p}K_a$  of the indicator and the pH of the solution:

$$\text{pH} = \text{p}K_a + \log\left(\frac{[\text{In}^-]}{[\text{HIn}]}\right)$$

- When  $\text{pH} = \text{p}K_a - 1$ ,  $\frac{[\text{In}^-]}{[\text{HIn}]} = 1/10$  and the acid (HIn) color is seen.
- When  $\text{pH} = \text{p}K_a$ ,  $\frac{[\text{In}^-]}{[\text{HIn}]} = 1$  and the acid (HIn) and base ( $\text{In}^-$ ) colors merge into an intermediate hue.
- When  $\text{pH} = \text{p}K_a + 1$ ,  $\frac{[\text{In}^-]}{[\text{HIn}]} = 10/1$  and the base ( $\text{In}^-$ ) color is seen.

Thus, an indicator has a *color range* equal to a  $10^2$ -fold range in the  $[\text{In}^-]/[\text{HIn}]$  ratio (from 1/10, or 0.1, to 10/1, or 10): an *indicator changes color over a range of about 2 pH units approximately centered around its  $\text{p}K_a$* :

$$\text{pH of indicator color change} \approx \text{p}K_a \text{ of indicator} \pm 1$$

For example, bromothymol blue ( $\text{p}K_a = 7.0$ ) has a pH range of about 6.0 to 7.6. As Figure 19.10 shows, it is yellow below a pH of 6.0 (*left*), blue above a pH of 7.6 (*right*), and greenish in between (*center*).

**Choosing an Acid-Base Indicator** During an acid-base titration, we are generally interested in the *equivalence point* of the titration, which must be distinguished from the *end point*:

- The equivalence point occurs when the number of moles of added  $\text{OH}^-$  (or  $\text{H}_3\text{O}^+$ ) equals the number of moles of  $\text{H}_3\text{O}^+$  (or  $\text{OH}^-$ ) originally present in the flask.
- The **end point** occurs when the indicator, which we added before the titration began, changes color. *We choose an indicator with a color change close to the pH of the equivalence point because we want the visible end point to signal the invisible equivalence point.*

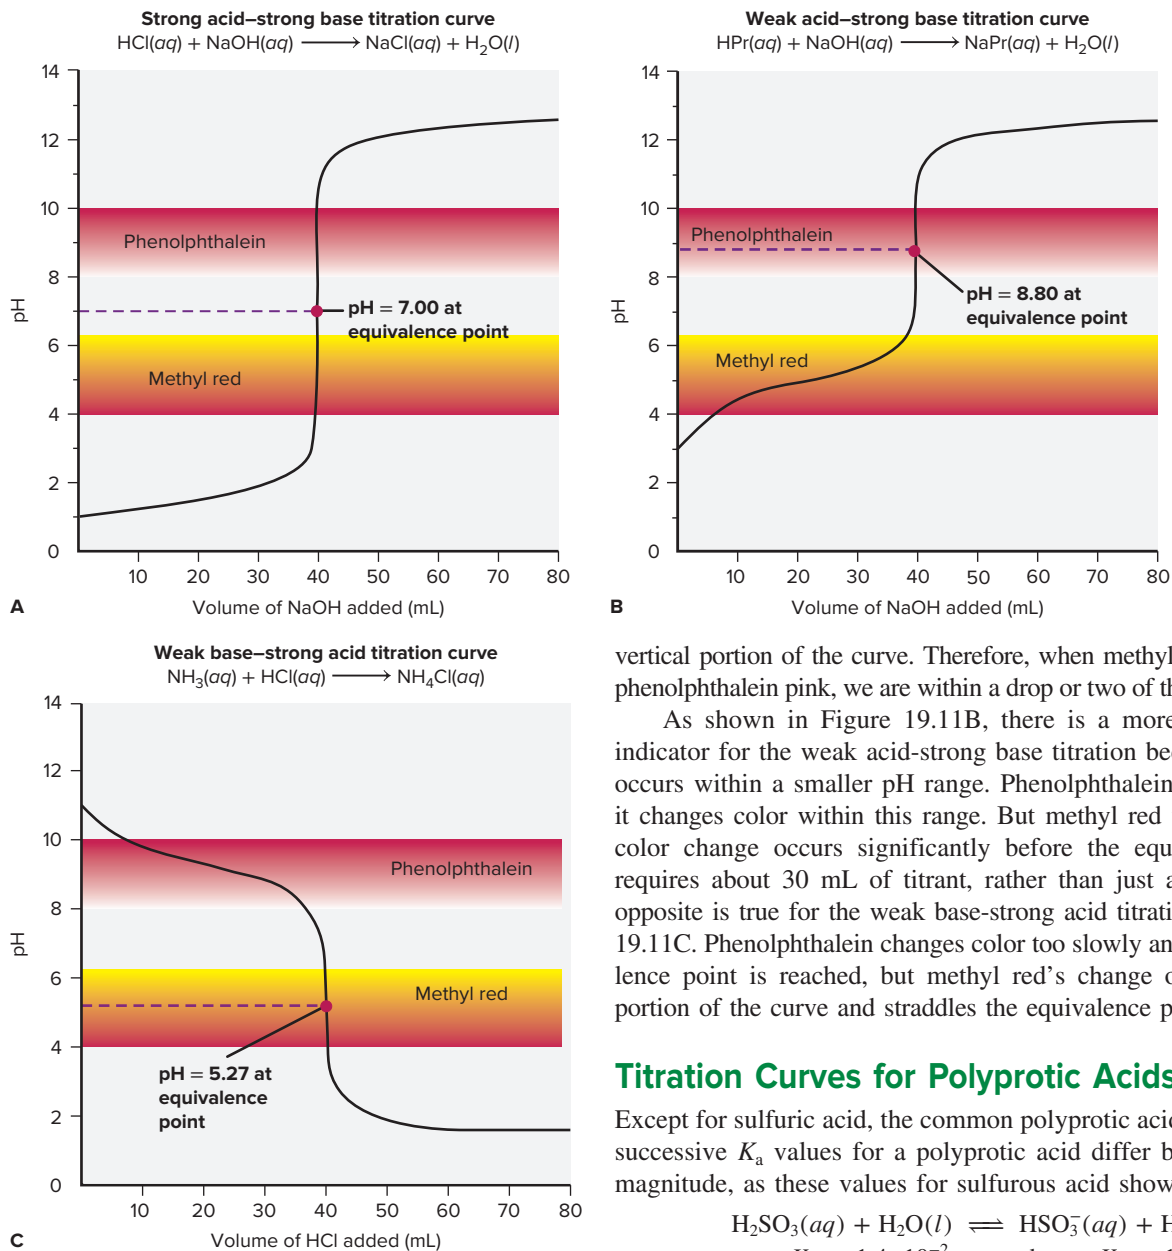

Figure 19.11 on the next page shows titration curves for the three titrations we examined earlier in this section, with the color change of two indicators, methyl red and phenolphthalein, superimposed on the curves. Figure 19.11A shows that both indicators are suitable for a strong acid-strong base titration. Methyl red changes from red at pH 4.2 to yellow at pH 6.3, and phenolphthalein changes from colorless at pH 8.3 to pink at pH 10.0. Neither change occurs at the equivalence point (pH = 7.00), but both occur on the

**Figure 19.10** The color change of the indicator bromothymol blue.

**Figure 19.11** Acid-base indicator selection for different acid-base titrations.

vertical portion of the curve. Therefore, when methyl red turns yellow or phenolphthalein pink, we are within a drop or two of the equivalence point.

As shown in Figure 19.11B, there is a more limited choice of indicator for the weak acid–strong base titration because the steep rise occurs within a smaller pH range. Phenolphthalein will work because it changes color within this range. But methyl red will not because its color change occurs significantly before the equivalence point and requires about 30 mL of titrant, rather than just a drop or two. The opposite is true for the weak base–strong acid titration shown in Figure 19.11C. Phenolphthalein changes color too slowly and before the equivalence point is reached, but methyl red's change occurs on the steep portion of the curve and straddles the equivalence point.

## Titration Curves for Polyprotic Acids

Except for sulfuric acid, the common polyprotic acids are all weak. The successive  $K_a$  values for a polyprotic acid differ by several orders of magnitude, as these values for sulfurous acid show:

In a titration of a diprotic acid such as  $\text{H}_2\text{SO}_3$ , two  $\text{OH}^-$  ions are required to react with the two  $\text{H}^+$  ions of each acid molecule. Figure 19.12 shows the titration curve for sulfurous acid with strong base. Because of the large difference in  $K_a$  values, each mole of  $\text{H}^+$  is titrated separately, so  $\text{H}_2\text{SO}_3$  molecules lose one  $\text{H}^+$  before any  $\text{HSO}_3^-$  ions do:

Several features of the curve are

- The same amount of base ( $0.004000 \text{ mol OH}^-$ ) is required per mole of  $\text{H}^+$ .
- There are two equivalence points and two buffer regions. The pH at the midpoint of each buffer region is equal to the  $\text{p}K_a$  of the acidic species present then.
- The pH of the first equivalence point is below 7.00, because  $\text{HSO}_3^-$  is a stronger acid than it is a base ( $K_a$  of  $\text{HSO}_3^- = 6.5 \times 10^{-8}$ ;  $K_b$  of  $\text{HSO}_3^- = 7.1 \times 10^{-13}$ ).
- The pH of the second equivalence point is above 7.00, because  $\text{SO}_3^{2-}$  acts as a weak base and accepts a proton from  $\text{H}_2\text{O}$  to yield  $\text{OH}^-$ .

**Figure 19.12** Curve for the titration of a weak polyprotic acid.

## Amino Acids as Biological Polyprotic Acids

Amino acids have the general formula  $NH_2-CH(R)-COOH$ , where R can be one of about 20 different groups (Sections 13.2 and 15.6). In essence, amino acids contain a weak base ( $-NH_2$ ) and a weak acid ( $-COOH$ ) on the same molecule. Both the amino and carboxylic acid groups are protonated at low pH:  $^+NH_3-CH(R)-COOH$ . Thus, in this form, the amino acid behaves like a polyprotic acid. For glycine, the simplest amino acid ( $R = H$ ), the dissociation reactions and  $pK_a$  values are

These values show that the  $-COOH$  group is *much* more acidic than the  $-NH_3^+$  group. As we saw with  $H_2SO_3$ , the acidic protons (*black circles*) are titrated separately, so all the  $-COOH$  protons are removed before any  $-NH_3^+$  protons are:

Thus, at physiological pH ( $\sim 7$ ), which is between the two  $pK_a$  values, *an amino acid exists as a zwitterion* (German *zwitter*, “double”), a species with opposite charges on the same molecule; the zwitterion of glycine is  $^+NH_3CH_2COO^-$ .

Of the 20 different R groups of amino acids, several have *additional*  $-COO^-$  or  $-NH_3^+$  groups at pH 7 (see Figure 15.30). When amino acids link to form a protein, their charged R groups give the protein its overall charge, which is often related to its function. A widely studied example of this relationship occurs in the hereditary disease sickle cell anemia. Normal red blood cells contain hemoglobin molecules that have two glutamic acid R groups ( $-CH_2CH_2COO^-$ ), each providing a negative charge at a critical region. Abnormal hemoglobin molecules in sickle cell anemia have two valine R groups ( $-CH_3$ ), which are uncharged, at the same region. This change in just 2 of hemoglobin’s 574 amino acids lowers charge repulsions between the hemoglobin molecules. As a result, they clump together in fiber-like structures, which leads to the sickle shape of the red blood cells (Figure 19.13). The misshapen cells block capillaries, and the painful course of sickle cell anemia usually ends in early death.

**Figure 19.13** Abnormal shape of red blood cells in sickle cell anemia.

### › Summary of Section 19.2

- › In a strong acid–strong base titration, the pH starts out low, rises slowly, then shoots up near the equivalence point ( $\text{pH} = 7$ ).
- › In a weak acid–strong base titration, the pH starts out higher, rises slowly in the buffer region ( $\text{pH} = \text{p}K_a$  at the midpoint), and then rises quickly near the equivalence point ( $\text{pH} > 7$ ).
- › A weak base–strong acid titration curve has a shape that is the inverse of the weak acid–strong base case, with the pH decreasing to the equivalence point ( $\text{pH} < 7$ ).
- › An acid–base (pH) indicator is a weak acid that has a differently colored conjugate base form and changes color over about 2 pH units.
- › Polyprotic acids have two or more acidic protons, each with its own  $K_a$  value. Because the  $K_a$ 's differ by several orders of magnitude, each proton is titrated separately.
- › Amino acids exist in charged forms that depend on the pH of the solution and determine the overall charge of a protein, which can affect the protein's function.

## 19.3 EQUILIBRIA OF SLIGHTLY SOLUBLE IONIC COMPOUNDS

In this section, we explore an equilibrium system that involves the solubility of ionic compounds. Recall from Chapter 13 that most solutes, even those called “soluble,” have a limited solubility in a particular solvent. In a saturated solution at a particular temperature, equilibrium exists between dissolved and undissolved solute. Slightly soluble ionic compounds, which we've been calling “insoluble,” reach equilibrium with very little solute dissolved. In this introductory discussion, we will *assume* that, as with a soluble ionic compound, the small amount of a slightly soluble ionic compound that does dissolve dissociates completely into ions.

### The Ion-Product Expression ( $Q_{\text{sp}}$ ) and the Solubility-Product Constant ( $K_{\text{sp}}$ )

For a slightly soluble ionic compound, *equilibrium exists between solid solute and aqueous ions*. Thus, for example, for a saturated solution of lead(II) fluoride, we have

As for any equilibrium system, we can write a reaction quotient:

$$Q_c = \frac{[\text{Pb}^{2+}][\text{F}^{-}]^2}{[\text{PbF}_2]}$$

And, as in earlier cases, the concentration term for the pure solid,  $[\text{PbF}_2]$  in this case, equals 1, and so we obtain a relationship called the *ion-product expression*,  $Q_{\text{sp}}$ :

$$Q_c \times 1 = Q_{\text{sp}} = [\text{Pb}^{2+}][\text{F}^{-}]^2$$

When the solution is saturated, the numerical value of  $Q_{\text{sp}}$  attains a constant value called the **solubility-product constant**,  $K_{\text{sp}}$ . The  $K_{\text{sp}}$  for  $\text{PbF}_2$  at  $25^\circ\text{C}$ , for example, is  $3.6 \times 10^{-8}$ . Like other equilibrium constants,  $K_{\text{sp}}$  depends *only* on the temperature, not on the individual ion concentrations.

The form of  $Q_{\text{sp}}$  is identical to that of other reaction quotients: each concentration is raised to an exponent equal to the coefficient for that species in the balanced equation, which in this case also *equals the subscript of each ion in the compound's formula*. At saturation, the concentration terms have their equilibrium values. Thus, in general, for a slightly soluble ionic compound,  $M_pX_q$ , composed of the ions  $M^{n+}$  and  $X^{z-}$ , the ion-product expression at equilibrium is

$$Q_{\text{sp}} = [\text{M}^{n+}]^p[\text{X}^{z-}]^q = K_{\text{sp}} \quad (19.2)$$

We'll write  $Q_{\text{sp}}$  directly using the symbol  $K_{\text{sp}}$ .

## SAMPLE PROBLEM 19.5

## Writing Ion-Product Expressions

**Problem** Write the ion-product expression at equilibrium for each compound: (a) magnesium carbonate; (b) iron(II) hydroxide; (c) calcium phosphate; (d) silver sulfide.

**Plan** We write an equation for a saturated solution and then write the ion-product expression at equilibrium,  $K_{sp}$  (Equation 19.2).

**Solution** (a) Magnesium carbonate:

(b) Iron(II) hydroxide:

(c) Calcium phosphate:

(d) Silver sulfide:

**Check** You can check by using the exponents as subscripts to see if you obtain the formula of the compound from  $K_{sp}$ .

**Comment** The  $\text{S}^{2-}$  ion in  $\text{Ag}_2\text{S}$  in part (d) is so basic that it reacts completely with water to form the hydrogen sulfide ion ( $\text{HS}^-$ ) and  $\text{OH}^-$ :

We more correctly write the ion-product expression for  $\text{Ag}_2\text{S}$  (and other metal sulfides) by replacing  $[\text{S}^{2-}]$  with  $[\text{HS}^-][\text{OH}^-]$ :

$$K_{sp} = [\text{Ag}^+]^2[\text{HS}^-][\text{OH}^-]$$

However, as a simplification, we will present the ion-product expression for a metal sulfide in terms of  $[\text{S}^{2-}]$ , as shown in part (d) of this sample problem.

## FOLLOW-UP PROBLEMS

**19.5A** Write the ion-product expression at equilibrium for each compound: (a) calcium sulfate; (b) chromium(III) carbonate; (c) magnesium hydroxide; (d) aluminum hydroxide.

**19.5B** Write the formula and give the name of the compound having each ion-product expression: (a)  $K_{sp} = [\text{Pb}^{2+}][\text{CrO}_4^{2-}]$ ; (b)  $K_{sp} = [\text{Fe}^{2+}][\text{S}^{2-}]$ ; (c)  $K_{sp} = [\text{Sr}^{2+}][\text{F}^-]^2$ ;

(d)  $K_{sp} = [\text{Cu}^{2+}]^3[\text{PO}_4^{3-}]^2$ .

**SOME SIMILAR PROBLEMS** 19.67–19.70

## Calculations Involving the Solubility-Product Constant

In Chapters 17 and 18, we considered two types of equilibrium problems. In one type, we use concentrations (or other quantities) to find  $K$ , and in the other, we use  $K$  to find concentrations. Here we encounter the same two types.

**The Problem with Assuming Complete Dissociation** Before we focus on calculations, let's address a complication that affects accuracy and results in approximate answers. Our assumption that the small dissolved amount of these compounds dissociates completely into separate ions is an oversimplification. Many slightly soluble salts have polar covalent metal-nonmetal bonds (Section 9.5), and partially dissociated or even undissociated species occur in solution. Here are two of many examples:

- With slightly soluble lead(II) chloride, the aqueous solution contains not only the separate  $\text{Pb}^{2+}(aq)$  and  $\text{Cl}^-(aq)$  ions we expect from complete dissociation, but also undissociated  $\text{PbCl}_2(aq)$  molecules and  $\text{PbCl}^+(aq)$  ions.
- In an aqueous solution of  $\text{CaSO}_4$ , undissociated ion pairs,  $\text{Ca}^{2+}\text{SO}_4^{2-}(aq)$ , are present.

These partly dissociated and undissociated species increase the *apparent* solubility of a slightly soluble salt above the value obtained by assuming complete dissociation.

**Solubility-Product Constants ( $K_{sp}$ ) of Selected Ionic Compounds at 25°C**

Table 19.2

Name, Formula	$K_{sp}$
Aluminum hydroxide, $\text{Al}(\text{OH})_3$	$3 \times 10^{-34}$
Cobalt(II) carbonate, $\text{CoCO}_3$	$1.0 \times 10^{-10}$
Iron(II) hydroxide, $\text{Fe}(\text{OH})_2$	$4.1 \times 10^{-15}$
Lead(II) fluoride, $\text{PbF}_2$	$3.6 \times 10^{-8}$
Lead(II) sulfate, $\text{PbSO}_4$	$1.6 \times 10^{-8}$
Mercury(I) iodide, $\text{Hg}_2\text{I}_2$	$4.7 \times 10^{-29}$
Silver sulfide, $\text{Ag}_2\text{S}$	$8 \times 10^{-48}$
Zinc iodate, $\text{Zn}(\text{IO}_3)_2$	$3.9 \times 10^{-6}$

More advanced courses discuss these factors, but we simply mention them in the Comments of several sample problems. Thus, it is best to view the specific results of the calculations as first approximations.

**The Meaning of  $K_{sp}$  and How to Determine It from Solubility Values** The  $K_{sp}$  value indicates *how far the dissolution proceeds at equilibrium (saturation)*. Table 19.2 presents a few  $K_{sp}$  values; Appendix C lists many more. Note that all the values are low, but they range over many orders of magnitude. In Sample Problem 19.6, we find the  $K_{sp}$  from the solubility of a compound.

## SAMPLE PROBLEM 19.6

Determining  $K_{sp}$  from Solubility

**Problem** (a) Lead(II) sulfate ( $\text{PbSO}_4$ ) is a key component in lead-acid car batteries. Its solubility in water at 25°C is  $4.25 \times 10^{-3}$  g/100. mL solution. What is the  $K_{sp}$  of  $\text{PbSO}_4$ ? (b) When lead(II) fluoride ( $\text{PbF}_2$ ) is shaken with pure water at 25°C, the solubility is found to be 0.64 g/L. Calculate the  $K_{sp}$  of  $\text{PbF}_2$ .

**Plan** We are given solubilities in various units and must find  $K_{sp}$  values. As always, we write the dissolution equation and ion-product expression for each compound, which show the number of moles of each ion. We use the molar mass to convert the solubility of the compound from the given mass units to *molar solubility* (molarity), then use that value to find the molarity of each ion, and substitute into the ion-product expression to calculate  $K_{sp}$ .

**Solution** (a) For  $\text{PbSO}_4$ . Writing the equation and ion-product ( $K_{sp}$ ) expression:

Converting solubility to molar solubility:

$$\begin{aligned} \text{Molar solubility of PbSO}_4 &= \frac{0.00425 \text{ g PbSO}_4}{100. \text{ mL soln}} \times \frac{1000 \text{ mL}}{1 \text{ L}} \times \frac{1 \text{ mol PbSO}_4}{303.3 \text{ g PbSO}_4} \\ &= 1.40 \times 10^{-4} \text{ M PbSO}_4 \end{aligned}$$

Determining molarities of the ions: Because 1 mol of  $\text{Pb}^{2+}$  and 1 mol of  $\text{SO}_4^{2-}$  form when 1 mol of  $\text{PbSO}_4$  dissolves,  $[\text{Pb}^{2+}] = [\text{SO}_4^{2-}] = 1.40 \times 10^{-4} \text{ M}$ .

Substituting these values into the ion-product expression to calculate  $K_{sp}$ :

$$K_{sp} = [\text{Pb}^{2+}][\text{SO}_4^{2-}] = (1.40 \times 10^{-4})^2 = 1.96 \times 10^{-8}$$

(b) For  $\text{PbF}_2$ . Writing the equation and  $K_{sp}$  expression:

Converting solubility to molar solubility:

$$\text{Molar solubility of PbF}_2 = \frac{0.64 \text{ g PbF}_2}{1 \text{ L soln}} \times \frac{1 \text{ mol PbF}_2}{245.2 \text{ g PbF}_2} = 2.6 \times 10^{-3} \text{ M PbF}_2$$

Determining molarities of the ions: Since 1 mol of  $\text{Pb}^{2+}$  and 2 mol of  $\text{F}^-$  form when 1 mol of  $\text{PbF}_2$  dissolves, we have

$$[\text{Pb}^{2+}] = 2.6 \times 10^{-3} \text{ M} \quad \text{and} \quad [\text{F}^-] = 2(2.6 \times 10^{-3} \text{ M}) = 5.2 \times 10^{-3} \text{ M}$$

Substituting these values into the ion-product expression to calculate  $K_{sp}$ :

$$K_{sp} = [\text{Pb}^{2+}][\text{F}^-]^2 = (2.6 \times 10^{-3})(5.2 \times 10^{-3})^2 = 7.0 \times 10^{-8}$$

**Check** The low solubilities are consistent with  $K_{sp}$  values being small. (a) The molar solubility seems about right:  $\sim \frac{4 \times 10^{-2} \text{ g/L}}{3 \times 10^2 \text{ g/mol}} \approx 1.3 \times 10^{-4} \text{ M}$ . Squaring this number gives

$1.7 \times 10^{-8}$ , close to the calculated  $K_{sp}$ . (b) Let's check the math in the final step as follows:  $\sim (3 \times 10^{-3})(5 \times 10^{-3})^2 = 7.5 \times 10^{-8}$ , close to the calculated  $K_{sp}$ .

**Comment 1.** In part (b), the formula  $\text{PbF}_2$  means that  $[\text{F}^-]$  is twice  $[\text{Pb}^{2+}]$ . We follow the ion-product expression exactly and square this value of  $[\text{F}^-]$ .

**2.** The tabulated  $K_{sp}$  values for these compounds (Table 19.2) are lower than our calculated values. For  $\text{PbF}_2$ , for instance, the tabulated value is  $3.6 \times 10^{-8}$ , but we calculated  $7.0 \times 10^{-8}$  from solubility data. The discrepancy arises because we assumed that  $\text{PbF}_2$  in solution dissociates completely to  $\text{Pb}^{2+}$  and  $\text{F}^-$ . Here is an example of the

complication pointed out earlier. Actually, about a third of the  $\text{PbF}_2$  dissolves as  $\text{PbF}^+(aq)$  and a small amount dissolves as undissociated  $\text{PbF}_2(aq)$ . The solubility given in the problem statement (0.64 g/L) is determined experimentally and includes these other species, which we did *not* include in our calculation.

### FOLLOW-UP PROBLEMS

**19.6A** When fluorite ( $\text{CaF}_2$ ; see photo) is pulverized and shaken in water at  $18^\circ\text{C}$ , 10.0 mL of the solution contains  $1.5 \times 10^{-4}$  g of solute. Find the  $K_{\text{sp}}$  of  $\text{CaF}_2$  at  $18^\circ\text{C}$ .

**19.6B** At  $20^\circ\text{C}$ ,  $3.2 \times 10^{-4}$  g of silver phosphate ( $\text{Ag}_3\text{PO}_4$ ) is soluble in 50. mL of solution. Find the  $K_{\text{sp}}$  of  $\text{Ag}_3\text{PO}_4$  at  $20^\circ\text{C}$ .

**SOME SIMILAR PROBLEMS** 19.71–19.74

A sample of fluorite.

Source: © Joel Arem/Science Source

**Determining Solubility from  $K_{\text{sp}}$**  The reverse of Sample Problem 19.6 involves finding the solubility of a compound based on its formula and  $K_{\text{sp}}$  value. We'll use an approach similar to the one we used for weak acids in Sample Problem 18.8: we define the unknown amount dissolved—the molar solubility—as  $S$ , include ion concentrations in terms of this unknown in a reaction table, and solve for  $S$ .

### SAMPLE PROBLEM 19.7

### Determining Solubility from $K_{\text{sp}}$

**Problem** Calcium hydroxide (slaked lime) is a major component of mortar, plaster, and cement, and solutions of  $\text{Ca}(\text{OH})_2$  are used in industry as a strong, inexpensive base. Calculate the molar solubility of  $\text{Ca}(\text{OH})_2$  in water given that the  $K_{\text{sp}}$  is  $6.5 \times 10^{-6}$ .

**Plan** We write the dissolution equation and the ion-product expression. We know  $K_{\text{sp}}$  ( $6.5 \times 10^{-6}$ ), so to find molar solubility ( $S$ ), we set up a reaction table that expresses  $[\text{Ca}^{2+}]$  and  $[\text{OH}^-]$  in terms of  $S$ , substitute into the ion-product expression, and solve for  $S$ .

**Solution** Writing the equation and ion-product expression:

Setting up a reaction table, with  $S$  = molar solubility:

Concentration (M)	$\text{Ca}(\text{OH})_2(s)$	$\rightleftharpoons$	$\text{Ca}^{2+}(aq)$	+	$2\text{OH}^-(aq)$
Initial	—		0		0
Change	—		+ $S$		+ $2S$
Equilibrium	—		$S$		$2S$

Substituting into the ion-product expression and solving for  $S$ :

$$K_{\text{sp}} = [\text{Ca}^{2+}][\text{OH}^-]^2 = (S)(2S)^2 = (S)(4S^2) = 4S^3 = 6.5 \times 10^{-6}$$

$$S = \sqrt[3]{\frac{6.5 \times 10^{-6}}{4}} = 1.2 \times 10^{-2} M$$

**Check** We expect a low solubility from a slightly soluble salt. If we reverse the calculation, we should obtain the given  $K_{\text{sp}}$ :  $4(1.2 \times 10^{-2})^3 = 6.9 \times 10^{-6}$ , which is close to  $6.5 \times 10^{-6}$ .

**Comment 1.** Note that we did not double and *then* square  $[\text{OH}^-]$ .  $2S$  is the  $[\text{OH}^-]$ , so we just squared it, as the ion-product expression required.

**2.** Once again, we assumed that the solid dissociates completely. Actually, the solubility is increased to about  $2.0 \times 10^{-2} M$  by the presence of  $\text{CaOH}^+(aq)$  formed in the reaction  $\text{Ca}(\text{OH})_2(s) \rightleftharpoons \text{CaOH}^+(aq) + \text{OH}^-(aq)$ . Our calculated answer is only approximate because we did not take this other species into account.

### FOLLOW-UP PROBLEMS

**19.7A** Milk of magnesia, a suspension of  $\text{Mg}(\text{OH})_2$  in water, relieves indigestion by neutralizing stomach acid. What is the molar solubility of  $\text{Mg}(\text{OH})_2$  ( $K_{\text{sp}} = 6.3 \times 10^{-10}$ ) in water?

**19.7B** Calcium phosphate,  $\text{Ca}_3(\text{PO}_4)_2$ , is used as a dietary supplement to treat low blood calcium. What is the molar solubility of  $\text{Ca}_3(\text{PO}_4)_2$  ( $K_{\text{sp}} = 1.2 \times 10^{-29}$ ) in water?

**SOME SIMILAR PROBLEMS** 19.75(a) and 19.76(a)

3	CaF <sub>2</sub>	1/2	$3.2 \times 10^{-11}$	$2.0 \times 10^{-4}$
3	Ag <sub>2</sub> CrO <sub>4</sub>	2/1	$2.6 \times 10^{-12}$	$8.7 \times 10^{-5}$

**Using  $K_{sp}$  Values to Compare Solubilities** As long as we compare compounds with the *same total number of ions* in their formulas,  $K_{sp}$  values indicate *relative solubility: the higher the  $K_{sp}$ , the greater the solubility* (Table 19.3). Note that for compounds that form three ions, the relationship holds whether the cation/anion ratio is 1/2 or 2/1, because the mathematical expression containing  $S$  is the same ( $4S^3$ ) in the calculation (see Sample Problem 19.7).

### Effect of a Common Ion on Solubility

From Le Châtelier's principle (Section 17.6), we know that *adding a common ion decreases the solubility of a slightly soluble ionic compound*. Consider a saturated solution of lead(II) chromate:

At a given temperature,  $K_{sp}$  depends on the product of the ion concentrations. If the concentration of either ion goes up, the other goes down to maintain  $K_{sp}$ . Suppose we add Na<sub>2</sub>CrO<sub>4</sub>, a soluble salt, to the saturated PbCrO<sub>4</sub> solution. The concentration of the common ion, CrO<sub>4</sub><sup>2-</sup>, increases, and some of it combines with Pb<sup>2+</sup> ion to form more solid PbCrO<sub>4</sub> (Figure 19.14). That is, the equilibrium position shifts to the left:

As a result of the addition, [Pb<sup>2+</sup>] is lower. And, since [Pb<sup>2+</sup>] defines the solubility of PbCrO<sub>4</sub>, in effect, the solubility of PbCrO<sub>4</sub> has decreased. Note that we would get the same result if Na<sub>2</sub>CrO<sub>4</sub> solution were the solvent; that is, PbCrO<sub>4</sub> is more soluble in water than in aqueous Na<sub>2</sub>CrO<sub>4</sub>.

**Figure 19.14** The effect of a common ion on solubility.

## SAMPLE PROBLEM 19.8

## Calculating the Effect of a Common Ion on Solubility

**Problem** In Sample Problem 19.7, we calculated the solubility of  $\text{Ca(OH)}_2$  in water. What is its solubility in  $0.10\text{ M Ca(NO}_3)_2$  ( $K_{\text{sp}}$  of  $\text{Ca(OH)}_2 = 6.5 \times 10^{-6}$ )?

**Plan** Addition of  $\text{Ca}^{2+}$ , the common ion, should lower the solubility. We write the equation and ion-product expression and set up a reaction table, with  $[\text{Ca}^{2+}]_{\text{init}}$  reflecting the  $0.10\text{ M Ca(NO}_3)_2$  and  $S$  equal to  $[\text{Ca}^{2+}]_{\text{from Ca(OH)}_2}$ . To simplify the math, we assume that, because  $K_{\text{sp}}$  is low,  $S$  is so small relative to  $[\text{Ca}^{2+}]_{\text{init}}$  that it can be neglected. Then we solve for  $S$  and check the assumption.

**Solution**  $\text{Ca(NO}_3)_2$  is a soluble salt that dissociates completely in water; in a solution of  $0.10\text{ M Ca(NO}_3)_2$ ,  $[\text{Ca}^{2+}] = 0.10\text{ M}$ , and  $\text{NO}_3^-$  is a spectator ion that does not affect the solubility of  $\text{Ca(OH)}_2$ .

Writing the equation and ion-product expression for  $\text{Ca(OH)}_2$ :

Setting up the reaction table, with  $S = [\text{Ca}^{2+}]_{\text{from Ca(OH)}_2}$ :

Concentration (M)	$\text{Ca(OH)}_2(s)$	$\rightleftharpoons$	$\text{Ca}^{2+}(aq)$	+	$2\text{OH}^-(aq)$
Initial	—		0.10 (from $\text{Ca(NO}_3)_2$ )		0
Change	—		+ $S$ (from $\text{Ca(OH)}_2$ )		+ $2S$
Equilibrium	—		$0.10 + S$		$2S$

Making the assumption:  $K_{\text{sp}}$  is small, so  $S \ll 0.10\text{ M}$ ; thus,  $0.10\text{ M} + S \approx 0.10\text{ M}$ . Substituting into the ion-product expression and solving for  $S$ :

$$K_{\text{sp}} = [\text{Ca}^{2+}][\text{OH}^-]^2 = 6.5 \times 10^{-6} \approx (0.10)(2S)^2$$

Therefore,  $4S^2 \approx \frac{6.5 \times 10^{-6}}{0.10}$  so  $S \approx \sqrt{\frac{6.5 \times 10^{-5}}{4}} = 4.0 \times 10^{-3}\text{ M}$

Checking the assumption by comparing the magnitude of  $S$  to  $0.10\text{ M}$ :

$$\frac{4.0 \times 10^{-3}\text{ M}}{0.10\text{ M}} \times 100 = 4.0\% < 5\%$$

**Check** In Sample Problem 19.7, the solubility of  $\text{Ca(OH)}_2$  was  $0.012\text{ M}$ ; here it is  $0.0040\text{ M}$ , one-third as much. As expected, the solubility *decreased* in the presence of added  $\text{Ca}^{2+}$ , the common ion.

## FOLLOW-UP PROBLEMS

**19.8A** To improve the x-ray image used to diagnose an intestinal disorder, a patient drinks an aqueous suspension of  $\text{BaSO}_4$ , because  $\text{Ba}^{2+}$  is opaque to x-rays (*photo*). However,  $\text{Ba}^{2+}$  is also toxic; thus,  $[\text{Ba}^{2+}]$  is lowered by adding dilute  $\text{Na}_2\text{SO}_4$ . What is the solubility of  $\text{BaSO}_4$  ( $K_{\text{sp}} = 1.1 \times 10^{-10}$ ) in (a) water and (b)  $0.10\text{ M Na}_2\text{SO}_4$ ?

**19.8B** Calculate the solubility of  $\text{CaF}_2$  ( $K_{\text{sp}} = 3.2 \times 10^{-11}$ ) in (a) water, (b)  $0.20\text{ M CaCl}_2$ , and (c)  $0.20\text{ M NiF}_2$ .

**SOME SIMILAR PROBLEMS** 19.75(b), 19.76(b), 19.77, and 19.78

## Effect of pH on Solubility

If a slightly soluble ionic compound contains the anion of a weak acid, *addition of  $\text{H}_3\text{O}^+$  (from a strong acid) increases the compound's solubility*. Once again, Le Châtelier's principle explains why. Consider a saturated solution of calcium carbonate:

Adding strong acid introduces  $\text{H}_3\text{O}^+$ , which reacts with the anion of a weak acid,  $\text{CO}_3^{2-}$ , to form the anion of another weak acid,  $\text{HCO}_3^-$ :

**Figure 19.15** Test for the presence of a carbonate. When a carbonate mineral is treated with HCl, bubbles of CO<sub>2</sub> form.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

If enough H<sub>3</sub>O<sup>+</sup> is added, carbonic acid forms, which decomposes to H<sub>2</sub>O and CO<sub>2</sub>, and the gas escapes the container:

The net effect of adding H<sub>3</sub>O<sup>+</sup> is a shift in the equilibrium position to the right, and more CaCO<sub>3</sub> dissolves:

In fact, this example illustrates a qualitative field test for carbonate minerals because the CO<sub>2</sub> bubbles vigorously (Figure 19.15).

In contrast, adding H<sub>3</sub>O<sup>+</sup> to a saturated solution of a slightly soluble ionic compound that contains a strong-acid anion, such as AgCl, has no effect on its solubility:

The Cl<sup>-</sup> ion can coexist with high [H<sub>3</sub>O<sup>+</sup>], so the equilibrium position is not affected.

### SAMPLE PROBLEM 19.9

### Predicting the Effect on Solubility of Adding Strong Acid

**Problem** Write balanced equations to explain whether addition of H<sub>3</sub>O<sup>+</sup> from a strong acid affects the solubility of each ionic compound:

- (a) Lead(II) bromide                      (b) Copper(II) hydroxide                      (c) Iron(II) sulfide

**Plan** We write the balanced dissolution equation and note the anion:

- Weak-acid anions react with H<sub>3</sub>O<sup>+</sup> and increase solubility when a strong acid is added.
- Strong-acid anions do not react with H<sub>3</sub>O<sup>+</sup>, so addition of a strong acid has no effect.

**Solution** (a)  $\text{PbBr}_2(s) \rightleftharpoons \text{Pb}^{2+}(aq) + 2\text{Br}^-(aq)$

No effect. Br<sup>-</sup> is the anion of HBr, a strong acid, so it does not react with H<sub>3</sub>O<sup>+</sup>.

(b)  $\text{Cu}(\text{OH})_2(s) \rightleftharpoons \text{Cu}^{2+}(aq) + 2\text{OH}^-(aq)$

Increases solubility. OH<sup>-</sup> is the anion of H<sub>2</sub>O, a very weak acid, so it reacts with the added H<sub>3</sub>O<sup>+</sup>:

As OH<sup>-</sup> is removed from solution by this reaction, the solubility equilibrium shifts to the right and additional Cu(OH)<sub>2</sub> dissolves.

(c)  $\text{FeS}(s) \rightleftharpoons \text{Fe}^{2+}(aq) + \text{S}^{2-}(aq)$

Increases solubility. S<sup>2-</sup> is the anion of the weak acid HS<sup>-</sup>, so it reacts with the added H<sub>3</sub>O<sup>+</sup>, removing it from solution; the solubility equilibrium shifts to the right and additional FeS dissolves:

### FOLLOW-UP PROBLEMS

**19.9A** Write balanced equations to show how addition of HNO<sub>3</sub>(aq) affects the solubility of: (a) calcium fluoride; (b) iron(III) hydroxide; (c) silver iodide.

**19.9B** Write balanced equations to show how addition of HBr(aq) affects the solubility of: (a) silver cyanide; (b) copper(I) chloride; (c) magnesium phosphate.

## Applying Ionic Equilibria to the Formation of a Limestone Cave

Limestone caves and the remarkable structures within them provide striking evidence of the results of aqueous ionic equilibria involving carbonate rocks and the carbon dioxide and water that have flowed through them for many hundreds of millennia (Figure 19.16).

**The Cave-Forming Reactions** Limestone is mostly calcium carbonate ( $\text{CaCO}_3$ ;  $K_{\text{sp}} = 3.3 \times 10^{-9}$ ). Two key reactions help us understand how limestone caves form:

1. Gaseous  $\text{CO}_2$  in air is in equilibrium with aqueous  $\text{CO}_2$  in natural waters:

The concentration of aqueous  $\text{CO}_2$  is proportional to the partial pressure of  $\text{CO}_2(g)$  in contact with the water (Henry's law; Section 13.4):

$$[\text{CO}_2(aq)] \propto P_{\text{CO}_2}$$

Due to the continual release of  $\text{CO}_2$  from within Earth (outgassing),  $P_{\text{CO}_2}$  in soil-trapped air is *higher* than  $P_{\text{CO}_2}$  in the atmosphere.

2. The reaction of  $\text{CO}_2$  with water produces  $\text{H}_3\text{O}^+$ :

Thus, since  $\text{CaCO}_3$  contains the anion of a weak acid, this formation of  $\text{H}_3\text{O}^+$  increases the solubility of  $\text{CaCO}_3$ :

**The Cave-Forming Process** Here is an overview of the process that forms most limestone caves:

1. As surface water trickles through cracks in the ground, it meets soil-trapped air with a high  $P_{\text{CO}_2}$ . As a result,  $[\text{CO}_2(aq)]$  increases (equation 1 shifts to the right), and the solution becomes more acidic.
2. When this  $\text{CO}_2$ -rich water contacts  $\text{CaCO}_3$ , more  $\text{CaCO}_3$  dissolves (equation 2 shifts to the right). As a result, more rock is carved out, more water flows in, and so on. Centuries pass, and a cave slowly begins to form.
3. Some of the aqueous solution, dilute  $\text{Ca}(\text{HCO}_3)_2$ , passes through the ceiling of the growing cave. As it drips, it meets air, which has a lower  $P_{\text{CO}_2}$  than the soil, so some  $\text{CO}_2(aq)$  comes out of solution (equation 1 shifts to the left).
4. Consequently, some  $\text{CaCO}_3$  precipitates on the ceiling and on the floor below, where the drops land (equation 2 shifts to the left). After many decades, the ceiling bears a *stalactite*, while a spike, called a *stalagmite*, grows up from the floor. Eventually, they meet to form a column of precipitated limestone.

The same chemical process can lead to different shapes. Standing pools of  $\text{Ca}(\text{HCO}_3)_2$  solution form limestone “lily pads” or “corals.” Cascades of solution form delicate limestone “draperies” on a cave wall, with fabulous colors arising from trace metal ions, such as iron (reddish brown) or copper (bluish green).

### Predicting the Formation of a Precipitate: $Q_{\text{sp}}$ vs. $K_{\text{sp}}$

As in Section 17.4, here we compare the values of  $Q_{\text{sp}}$  and  $K_{\text{sp}}$  to see if a reaction has reached equilibrium and, if not, in which net direction it will progress until it does. Using solutions of *soluble* salts that contain the ions of *slightly* soluble salts, we can calculate the ion concentrations and predict the result when we mix the solutions:

- If  $Q_{\text{sp}} = K_{\text{sp}}$ , the solution is saturated and no change will occur.
- If  $Q_{\text{sp}} > K_{\text{sp}}$ , a precipitate will form until the remaining solution is saturated.
- If  $Q_{\text{sp}} < K_{\text{sp}}$ , no precipitate will form because the solution is unsaturated.

#### SAMPLE PROBLEM 19.10

#### Predicting Whether a Precipitate Will Form

**Problem** A common laboratory method for preparing a precipitate is to mix solutions containing the component ions. Does a precipitate form when 0.100 L of 0.30 M  $\text{Ca}(\text{NO}_3)_2$  is mixed with 0.200 L of 0.060 M NaF?

**Plan** First, we decide which slightly soluble salt could form, look up its  $K_{\text{sp}}$  value in Appendix C, and write a dissolution equation and ion-product expression. To see

Precipitation of  $\text{CaF}_2$ .

Source: © McGraw-Hill Education/  
Stephen Frisch, photographer

whether mixing these solutions forms the precipitate, we find the initial ion concentrations by calculating the amount (mol) of each ion from its concentration and volume, and dividing by the *total* volume because each solution dilutes the other. Finally, we substitute these concentrations to calculate  $Q_{\text{sp}}$ , and compare  $Q_{\text{sp}}$  with  $K_{\text{sp}}$ .

**Solution** The ions present are  $\text{Ca}^{2+}$ ,  $\text{Na}^+$ ,  $\text{F}^-$ , and  $\text{NO}_3^-$ . All sodium and all nitrate salts are soluble (Table 4.1), so the only possible compound that could precipitate is  $\text{CaF}_2$  ( $K_{\text{sp}} = 3.2 \times 10^{-11}$ ). Writing the equation and ion-product expression:

Calculating the ion concentrations:

$$\text{Amount (mol) of } \text{Ca}^{2+} = 0.30 \text{ M } \text{Ca}^{2+} \times 0.100 \text{ L} = 0.030 \text{ mol } \text{Ca}^{2+}$$

$$[\text{Ca}^{2+}]_{\text{init}} = \frac{0.030 \text{ mol } \text{Ca}^{2+}}{0.100 \text{ L} + 0.200 \text{ L}} = 0.10 \text{ M } \text{Ca}^{2+}$$

$$\text{Amount (mol) of } \text{F}^- = 0.060 \text{ M } \text{F}^- \times 0.200 \text{ L} = 0.012 \text{ mol } \text{F}^-$$

$$[\text{F}^-]_{\text{init}} = \frac{0.012 \text{ mol } \text{F}^-}{0.100 \text{ L} + 0.200 \text{ L}} = 0.040 \text{ M } \text{F}^-$$

Substituting into the ion-product expression and comparing  $Q_{\text{sp}}$  with  $K_{\text{sp}}$ :

$$Q_{\text{sp}} = [\text{Ca}^{2+}]_{\text{init}}[\text{F}^-]_{\text{init}}^2 = (0.10)(0.040)^2 = 1.6 \times 10^{-4}$$

Because  $Q_{\text{sp}} > K_{\text{sp}}$ ,  $\text{CaF}_2$  will precipitate until  $Q_{\text{sp}} = 3.2 \times 10^{-11}$ .

**Check** Make sure you round off and quickly check the math. For example,  $Q_{\text{sp}} = (1 \times 10^{-1})(4 \times 10^{-2})^2 = 1.6 \times 10^{-4}$ . With  $K_{\text{sp}}$  so low,  $\text{CaF}_2$  must have a low solubility, and given the sizable concentrations being mixed, we would expect  $\text{CaF}_2$  to precipitate.

### FOLLOW-UP PROBLEMS

**19.10A** As a result of mineral erosion and biological activity, phosphate ion is common in natural waters, where it often precipitates as insoluble salts such as  $\text{Ca}_3(\text{PO}_4)_2$ . If  $[\text{Ca}^{2+}]_{\text{init}} = [\text{PO}_4^{3-}]_{\text{init}} = 1.0 \times 10^{-9} \text{ M}$  in a given river, will  $\text{Ca}_3(\text{PO}_4)_2$  ( $K_{\text{sp}} = 1.2 \times 10^{-29}$ ) precipitate?

**19.10B** Addition of a soluble sulfide compound such as sodium sulfide is an effective way to remove metals such as lead from wastewater. Does a precipitate form when 0.500 L of 0.10 M  $\text{Na}_2\text{S}$  is added to 25 L of wastewater containing 0.015 g  $\text{Pb}^{2+}/\text{L}$ ?

**SOME SIMILAR PROBLEMS** 19.87–19.90

### SAMPLE PROBLEM 19.11

### Using Molecular Scenes to Predict Whether a Precipitate Will Form

**Problem** These four scenes represent solutions of silver (*gray*) and carbonate (*black and red*) ions above solid silver carbonate. (The solid, other ions, and water are not shown.)

- (a) Which scene best represents the solution in equilibrium with the solid?  
 (b) In which, if any, other scene(s) will additional solid silver carbonate form?  
 (c) Explain how, if at all, addition of a small volume of concentrated strong acid affects the  $[\text{Ag}^+]$  in scene 4 and the mass of solid present.

**Plan** (a) The solution of silver and carbonate ions in equilibrium with the solid ( $\text{Ag}_2\text{CO}_3$ ) should have the same relative numbers of cations and anions as in the formula. We examine the scenes to see which has a ratio of 2  $\text{Ag}^+$  to 1  $\text{CO}_3^{2-}$ . (b) A solid forms

if the value of  $Q_{sp}$  exceeds that of  $K_{sp}$ . We write the dissolution equation and  $Q_{sp}$  expression. Then we count ions to calculate  $Q_{sp}$  for each scene and see which  $Q_{sp}$  value, if any, exceeds the value for the scene identified in part (a). (c) The  $\text{CO}_3^{2-}$  ion reacts with added  $\text{H}_3\text{O}^+$ , so adding strong acid will shift the equilibrium to the right. We write the equations and determine how a shift to the right affects  $[\text{Ag}^+]$  and the mass of solid  $\text{Ag}_2\text{CO}_3$ .

**Solution** (a) **Scene 3** is the only one with an  $\text{Ag}^+/\text{CO}_3^{2-}$  ratio of 2/1, as in the solid's formula.

(b) Calculating the ion products:

Scene 1:  $Q_{sp} = (2)^2(4) = 16$       Scene 2:  $Q_{sp} = (3)^2(3) = 27$

Scene 3:  $Q_{sp} = (4)^2(2) = 32$       Scene 4:  $Q_{sp} = (3)^2(4) = 36$

Therefore, for scene 3,  $K_{sp} = 32$ ; the  $Q_{sp}$  value for **scene 4** is the only other one that equals or exceeds 32, so a precipitate of  $\text{Ag}_2\text{CO}_3$  will form there.

(c) Writing the equations:

The  $\text{CO}_2$  leaves as a gas, so adding  $\text{H}_3\text{O}^+$  shifts the equilibrium position of reaction 2 to the right. This change lowers the  $[\text{CO}_3^{2-}]$  in reaction 1, thereby causing more  $\text{CO}_3^{2-}$  to form. As a result, more solid dissolves, which means that the  $[\text{Ag}^+]$  increases and the mass of  $\text{Ag}_2\text{CO}_3$  decreases.

**Check** (a) In scene 1, the formula has two  $\text{CO}_3^{2-}$  per formula unit, not two  $\text{Ag}^+$ .

(b) Even though scene 4 has fewer  $\text{Ag}^+$  ions than scene 3, its  $Q_{sp}$  value is higher and exceeds the  $K_{sp}$ .

### FOLLOW-UP PROBLEMS

**19.11A** The following scenes represent solutions of nickel(II) (*gray*) and hydroxide (*red and blue*) ions that are above solid nickel(II) hydroxide. (The solid, other ions, and water are not shown.)

(a) Which scene best depicts the solution at equilibrium with the solid?

(b) In which, if any, other scene(s) will additional solid form?

(c) Will addition of a small amount of concentrated strong acid or strong base affect the mass of solid present in any scene? Explain.

**19.11B** The following scenes represent solutions of lead(II) (*black*) and chloride (*green*) ions that are above solid lead(II) chloride. (The solid, other ions, and water are not shown.)

(a) Which scene best represents the solution in equilibrium with the solid?

(b) In which, if any, other scene(s) will additional solid form?

(c) Explain how, if at all, addition of a small amount of concentrated  $\text{HCl}(aq)$  will affect the mass of solid present in any scene.

**SOME SIMILAR PROBLEMS** 19.121 and 19.147

## Separating Ions by Selective Precipitation and Simultaneous Equilibria

Let's consider two ways to separate one ion from another by reacting them with a given precipitating ion to form compounds with different solubilities.

**Selective Precipitation** In the process of **selective precipitation**, a solution of one precipitating ion is added to a solution of two ionic compounds until the  $Q_{sp}$  of the *more soluble* compound is almost equal to its  $K_{sp}$ . This method ensures that the  $K_{sp}$  of the *less soluble* compound is exceeded as much as possible. As a result, the maximum amount of the less soluble compound precipitates, but none of the more soluble compound does.

### SAMPLE PROBLEM 19.12

### Separating Ions by Selective Precipitation

**Problem** A solution consists of 0.20 M  $\text{MgCl}_2$  and 0.10 M  $\text{CuCl}_2$ . Calculate the  $[\text{OH}^-]$  needed to separate the metal ions. The  $K_{sp}$  of  $\text{Mg}(\text{OH})_2$  is  $6.3 \times 10^{-10}$ , and the  $K_{sp}$  of  $\text{Cu}(\text{OH})_2$  is  $2.2 \times 10^{-20}$ .

**Plan** Because both compounds have a 1/2 ratio of cation/anion (see the discussion on page 868), when we compare their  $K_{sp}$  values, we find that  $\text{Mg}(\text{OH})_2$  is about  $10^{10}$  times more soluble than  $\text{Cu}(\text{OH})_2$ ; thus,  $\text{Cu}(\text{OH})_2$  precipitates first. We write the dissolution equations and ion-product expressions. We are given both cation concentrations, so we solve for the  $[\text{OH}^-]$  that gives a saturated solution of  $\text{Mg}(\text{OH})_2$ , because this  $[\text{OH}^-]$  will precipitate the most  $\text{Cu}^{2+}$ . Then, we calculate the  $[\text{Cu}^{2+}]$  remaining to see if the separation was accomplished.

**Solution** Writing the equations and ion-product expressions:

Calculating the  $[\text{OH}^-]$  that gives a saturated  $\text{Mg}(\text{OH})_2$  solution:

$$[\text{OH}^-] = \sqrt{\frac{K_{sp}}{[\text{Mg}^{2+}]}} = \sqrt{\frac{6.3 \times 10^{-10}}{0.20}} = 5.6 \times 10^{-5} M$$

This is the maximum  $[\text{OH}^-]$  that will *not* precipitate  $\text{Mg}^{2+}$  ion.

Calculating the  $[\text{Cu}^{2+}]$  remaining in the solution with this  $[\text{OH}^-]$ :

$$[\text{Cu}^{2+}] = \frac{K_{sp}}{[\text{OH}^-]^2} = \frac{2.2 \times 10^{-20}}{(5.6 \times 10^{-5})^2} = 7.0 \times 10^{-12} M$$

Since the initial  $[\text{Cu}^{2+}]$  is 0.10 M, virtually all the  $\text{Cu}^{2+}$  ion is precipitated.

**Check** Rounding, we find that  $[\text{OH}^-]$  seems right:  $\sim \sqrt{(6 \times 10^{-10})/0.2} = 5 \times 10^{-5}$ . The  $[\text{Cu}^{2+}]$  remaining also seems correct:  $(2.2 \times 10^{-20})/(5 \times 10^{-5})^2 = 8 \times 10^{-12}$ .

### FOLLOW-UP PROBLEMS

**19.12A** A solution is 0.050 M  $\text{BaCl}_2$  and 0.025 M  $\text{CaCl}_2$ . What concentration of  $\text{SO}_4^{2-}$  will separate the cations in solution?  $K_{sp}$  of  $\text{BaSO}_4$  is  $1.1 \times 10^{-10}$ , and  $K_{sp}$  of  $\text{CaSO}_4$  is  $2.4 \times 10^{-5}$ .

**19.12B** A solution consists of 0.020 M  $\text{Ba}(\text{NO}_3)_2$  and 0.015 M  $\text{Ca}(\text{NO}_3)_2$ . What concentration of NaF will separate the cations in solution?  $K_{sp}$  of  $\text{BaF}_2$  is  $1.5 \times 10^{-6}$ , and  $K_{sp}$  of  $\text{CaF}_2$  is  $3.2 \times 10^{-11}$ .

**SOME SIMILAR PROBLEMS** 19.92 and 19.140

**Simultaneous Equilibria** Sometimes two or more equilibrium systems are controlled simultaneously to separate one metal ion from another as their sulfides, using  $\text{S}^{2-}$  as the precipitating ion. We control the  $[\text{S}^{2-}]$  in order to exceed the  $K_{sp}$  value of one metal sulfide but not the other, and we do so by shifting  $\text{H}_2\text{S}$  dissociation through adjustments of  $[\text{H}_3\text{O}^+]$ :

- If we add strong acid, the high  $[\text{H}_3\text{O}^+]$  shifts  $\text{H}_2\text{S}$  dissociation to the left, which decreases  $[\text{S}^{2-}]$ , so the *less* soluble sulfide precipitates.
- If we add strong base, the low  $[\text{H}_3\text{O}^+]$  shifts  $\text{H}_2\text{S}$  dissociation to the right, which increases  $[\text{S}^{2-}]$ , so the *more* soluble sulfide precipitates.

Thus, we shift one equilibrium system ( $\text{H}_2\text{S}$  dissociation) by adjusting a second ( $\text{H}_2\text{O}$  ionization) to control a third (metal sulfide solubility).

As the upcoming Chemical Connections essay demonstrates, the principles of ionic equilibria often help us understand the chemical basis of complex environmental problems and may provide ways to solve them.

### › Summary of Section 19.3

- › Only as a first approximation does the dissolved portion of a slightly soluble salt dissociate completely into ions.
- › In a saturated solution, dissolved ions and the undissolved solid salt are in equilibrium. The product of the ion concentrations, each raised to the power of its subscript in the formula, has a constant value ( $Q_{\text{sp}} = K_{\text{sp}}$ ).
- › The value of  $K_{\text{sp}}$  can be obtained from the solubility, and vice versa.
- › Adding a common ion lowers a compound's solubility.
- › Adding  $\text{H}_3\text{O}^+$  (lowering pH) increases an ionic compound's solubility if the anion of the compound is also that of a weak acid.
- › Limestone caves result from shifts in the  $\text{CaCO}_3/\text{CO}_2$  equilibrium system.
- › When two solutions, each containing one of the ions of a slightly soluble ionic compound, are mixed, an ionic solid forms if  $Q_{\text{sp}} > K_{\text{sp}}$ .
- › Ions are precipitated selectively from a solution of two ionic compounds by adding a precipitating ion until the  $K_{\text{sp}}$  of one compound is exceeded as much as possible without exceeding the  $K_{\text{sp}}$  of the other. An extension of this approach uses simultaneous control of three equilibrium systems to separate metal ions as their sulfides.
- › Lakes bounded by limestone-rich soils form buffer systems that prevent acidification.

## CHEMICAL CONNECTIONS TO ENVIRONMENTAL SCIENCE

### The Acid-Rain Problem

**A**cid rain, the deposition of acids in wet form as rain, snow, or fog or in dry form as solid particles, is a global environmental problem. It has been observed in the United States, Canada, Mexico, the Amazon basin, Europe, Russia, many parts of Asia, and even at the North and South Poles. Let's see how it arises and how to prevent some of its harmful effects.

#### Origins of Acid Rain

The strong acids  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$  cause the greatest concern, so let's see how they form (Figure B19.1, on the next page):

1. *Sulfuric acid.* Sulfur dioxide ( $\text{SO}_2$ ), produced mostly by the burning of high-sulfur coal, forms sulfurous acid ( $\text{H}_2\text{SO}_3$ ) in contact with water. The atmospheric pollutants hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) and ozone ( $\text{O}_3$ ) dissolve in the water in clouds and oxidize the sulfurous acid to sulfuric acid:

Alternatively,  $\text{SO}_2$  is oxidized by atmospheric hydroxyl radicals ( $\text{HO}\cdot$ ) to sulfur trioxide ( $\text{SO}_3$ ), which forms  $\text{H}_2\text{SO}_4$  with water.

2. *Nitric acid.* Nitrogen oxides ( $\text{NO}_x$ ) form from  $\text{N}_2$  and  $\text{O}_2$  during high-temperature combustion in car and truck engines and electric power plants.  $\text{NO}$  then forms  $\text{NO}_2$  and  $\text{HNO}_3$  in a process

that creates smog. At night,  $\text{NO}_x$  is converted to  $\text{N}_2\text{O}_5$ , which reacts with water to form  $\text{HNO}_3$ :

Ammonium salts, deposited as  $\text{NH}_4\text{HSO}_4$  or  $\text{NH}_4\text{NO}_3$ , produce  $\text{HNO}_3$  in soil through biochemical oxidation.

#### The pH of Acid Rain

Normal rainwater is weakly acidic from the reaction of atmospheric  $\text{CO}_2$  with water (see Problem 19.141):

Yet, as long ago as 1984, rainfall in the United States had already reached an average pH of 4.2, an increase of about 25 times as much  $\text{H}_3\text{O}^+$ . Rain in Wheeling, West Virginia, has had a pH of 1.8, lower than the pH of lemon juice. And rain in industrial parts of Sweden once had a pH of 2.7, about the same as vinegar.

#### Effects of Acid Rain

Some fish and shellfish die at pH values between 4.5 and 5.0. The young of most species are generally more vulnerable. At pH 5, most fish eggs cannot hatch. With tens of thousands of rivers and lakes around the world becoming or already acidified, the loss of freshwater fish became a major concern long ago.

(continued)

**Figure B19.1** Formation of acidic precipitation. A complex interplay of human activities, atmospheric chemistry, and environmental distribution leads to acidic precipitation and its harmful effects.

In addition, acres of forest have been harmed by the acid, which removes nutrients and releases toxic substances from the soil. The aluminosilicates that make up most soils are extremely insoluble in water. Through a complex series of simultaneous equilibria, contact with water at  $\text{pH} < 5$  causes these materials to release some bound  $\text{Al}^{3+}$ , which is toxic to fish and plants. At the same time, acid rain dissolves  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  ions from the soil, which are nutrients for plants and animals.

Marble and limestone (both primarily  $\text{CaCO}_3$ ) in buildings and monuments react with sulfuric acid to form gypsum ( $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ), which flakes off. Ironically, the same process that destroys these structures rescues lakes that are bounded by limestone-rich soil. Limestone dissolves sufficiently in lake water to form an  $\text{HCO}_3^-/\text{CO}_3^{2-}$  buffer capable of absorbing the incoming  $\text{H}_3\text{O}^+$  and maintaining a mildly basic pH:

Acidified lakes and rivers that are in contact with granite and other weathering-resistant bedrock can be remediated by *liming* (treating with limestone). This approach is expensive and is only a stopgap measure because the lakes are acidic again within several years.

## Preventing Acid Rain

Effective prevention of acid rain has to address the sources of the sulfur and nitrogen pollutants:

1. *Sulfur pollutants.* As was pointed out earlier (Chemical Connections, Chapter 6), the principal means of minimizing sulfur dioxide release is by “scrubbing” power plant emissions with limestone in both dry and wet form. Another method reduces  $\text{SO}_2$  with methane, coal, or  $\text{H}_2\text{S}$ , and the mixture is converted catalytically to sulfur, which is sold as a byproduct:

Although low-sulfur coal is rare and expensive to mine, coal can be converted into gaseous and liquid low-sulfur fuels.

The sulfur is removed (as  $\text{H}_2\text{S}$ ) in an acid-gas scrubber after gasification.

2. *Nitrogen pollutants.* Through the use of a catalytic converter in an auto exhaust system,  $\text{NO}_x$  species are reduced to  $\text{N}_2$ . In power plant emissions,  $\text{NO}_x$  is decreased by adjusting conditions and by treating hot stack gases with ammonia in the presence of a heterogeneous catalyst:

Reducing power plant emissions in North America and Europe has increased the pH of rainfall and some surface waters. Lime ( $\text{CaO}$ ) is routinely used to react with acid rain falling on croplands. Further progress is expected under current legislation, but, in much of eastern North America and northern Europe, additional measures are needed for full recovery.

## Problems

**B19.1** An environmental technician collects a sample of rainwater. Back in her lab, the pH meter isn’t working, so she uses indicator solutions to estimate the pH. A piece of litmus paper turns red, indicating acidity, so she divides the sample into thirds and obtains the following results: thymol blue turns yellow; bromphenol blue turns green; and methyl red turns red. Estimate the pH of the rainwater.

**B19.2** A lake that has a surface area of 10.0 acres (1 acre =  $4.840 \times 10^3 \text{ yd}^2$ ) receives 1.00 in of rain of pH 4.20. (Assume that the acidity of the rain is due to a strong, monoprotic acid.)

(a) How many moles of  $\text{H}_3\text{O}^+$  are in the rain falling on the lake?  
 (b) If the lake is unbuffered and its average depth is 10.0 ft before the rain, find the pH after the rain has been mixed with lake water. (Assume the initial pH is 7.00, and ignore runoff from the surrounding land.)  
 (c) If the lake contains hydrogen carbonate ions ( $\text{HCO}_3^-$ ), what mass of  $\text{HCO}_3^-$  will neutralize the acid in the rain?

## 19.4 EQUILIBRIA INVOLVING COMPLEX IONS

A third kind of aqueous ionic equilibrium involves a type of ion we mentioned briefly in Section 18.9. A *simple ion*, such as  $\text{Na}^+$  or  $\text{CH}_3\text{COO}^-$ , consists of one or a few bonded atoms, with an excess or deficit of electrons. A **complex ion** consists of a central metal ion covalently bonded to two or more anions or molecules, called **ligands**. Hydroxide, chloride, and cyanide ions are examples of ionic ligands; water, carbon monoxide, and ammonia are some molecular ligands. In the complex ion  $\text{Cr}(\text{NH}_3)_6^{3+}$ , for example, the central  $\text{Cr}^{3+}$  is surrounded by six  $\text{NH}_3$  ligands (Figure 19.17). Hydrated metal ions are complex ions with water molecules as ligands (Section 18.5). In Chapter 23, we discuss the transition metals and the structures and properties of the numerous complex ions they form. Here, we focus on equilibria of hydrated ions with ligands other than water.

Figure 19.17  $\text{Cr}(\text{NH}_3)_6^{3+}$ , a typical complex ion.

### Formation of Complex Ions

When a salt dissolves in water, a complex ion forms, with water as ligands around the metal ion. In many cases, when we treat this hydrated cation with a solution of another ligand, the bound water molecules are replaced by the other ligand. For example, a hydrated  $\text{M}^{2+}$  ion,  $\text{M}(\text{H}_2\text{O})_4^{2+}$ , forms the ammoniated ion,  $\text{M}(\text{NH}_3)_4^{2+}$ , in aqueous  $\text{NH}_3$ :

At equilibrium, this system is expressed by a ratio of concentration terms whose form follows that of any other equilibrium expression:

$$K_c = \frac{[\text{M}(\text{NH}_3)_4^{2+}][\text{H}_2\text{O}]^4}{[\text{M}(\text{H}_2\text{O})_4^{2+}][\text{NH}_3]^4}$$

Once again, because  $[\text{H}_2\text{O}]$  is essentially constant, water is treated as a pure liquid, with its concentration term equal to 1. Thus, we obtain the expression for a new equilibrium constant called the **formation constant,  $K_f$** :

$$\frac{K_c}{(1)^4} = K_f = \frac{[\text{M}(\text{NH}_3)_4^{2+}]}{[\text{M}(\text{H}_2\text{O})_4^{2+}][\text{NH}_3]^4}$$

At the molecular level, depicted in Figure 19.18 (*next page*), the actual process is stepwise, with ammonia molecules replacing water molecules one at a time. This process yields a series of intermediate species, each with its own formation constant:

$$K_{f1} = \frac{[\text{M}(\text{H}_2\text{O})_3(\text{NH}_3)^{2+}]}{[\text{M}(\text{H}_2\text{O})_4^{2+}][\text{NH}_3]}$$

$$K_{f2} = \frac{[\text{M}(\text{H}_2\text{O})_2(\text{NH}_3)_2^{2+}]}{[\text{M}(\text{H}_2\text{O})_3(\text{NH}_3)^{2+}][\text{NH}_3]}$$

$$K_{f3} = \frac{[\text{M}(\text{H}_2\text{O})(\text{NH}_3)_3^{2+}]}{[\text{M}(\text{H}_2\text{O})_2(\text{NH}_3)_2^{2+}][\text{NH}_3]}$$

$$K_{f4} = \frac{[\text{M}(\text{NH}_3)_4^{2+}]}{[\text{M}(\text{H}_2\text{O})(\text{NH}_3)_3^{2+}][\text{NH}_3]}$$

The *sum* of the equations gives the overall equation, so the *product* of the individual formation constants gives the overall formation constant:

$$K_f = K_{f1} \times K_{f2} \times K_{f3} \times K_{f4}$$

Recall that *all complex ions are Lewis adducts* (Section 18.9). The metal ion acts as a Lewis acid (accepts an electron pair), and the ligand acts as a Lewis base (donates an electron pair). In the formation of  $\text{M}(\text{NH}_3)_4^{2+}$ , the  $K_f$  for each step is

**Figure 19.18** The stepwise exchange of  $\text{NH}_3$  for  $\text{H}_2\text{O}$  in  $\text{M}(\text{H}_2\text{O})_4^{2+}$ . The molecular views show the first exchange and the fully amoniated ion.

much larger than 1 because ammonia is a stronger Lewis base than water. Therefore, if we add excess ammonia to the  $\text{M}(\text{H}_2\text{O})_4^{2+}$  solution, nearly all the  $\text{M}^{2+}$  ions exist as  $\text{M}(\text{NH}_3)_4^{2+}(\text{aq})$ .

Table 19.4 (and Appendix C) shows  $K_f$  values of some complex ions. Notice that they are all of the order  $10^6$  or greater, which means that these ions form readily from the hydrated ion. Because of this behavior, some uses of complex-ion formation are to retrieve a metal from its ore, eliminate a toxic or unwanted metal ion from a solution, or convert a metal ion to a different form, as Sample Problem 19.13 shows for the zinc ion.

**Table 19.4**

**Formation Constants ( $K_f$ ) of Some Complex Ions at 25°C**

Complex Ion	$K_f$	Complex Ion	$K_f$
$\text{Ag}(\text{CN})_2^-$	$3.0 \times 10^{20}$	$\text{Fe}(\text{CN})_6^{4-}$	$3 \times 10^{35}$
$\text{Ag}(\text{NH}_3)_2^+$	$1.7 \times 10^7$	$\text{Fe}(\text{CN})_6^{3-}$	$4.0 \times 10^{43}$
$\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}$	$4.7 \times 10^{13}$	$\text{Hg}(\text{CN})_4^{2-}$	$9.3 \times 10^{38}$
$\text{AlF}_6^{3-}$	$4 \times 10^{19}$	$\text{Ni}(\text{NH}_3)_6^{2+}$	$2.0 \times 10^8$
$\text{Al}(\text{OH})_4^-$	$3 \times 10^{33}$	$\text{Pb}(\text{OH})_5^-$	$8 \times 10^{13}$
$\text{Be}(\text{OH})_4^{2-}$	$4 \times 10^{18}$	$\text{Sn}(\text{OH})_5^-$	$3 \times 10^{25}$
$\text{CdI}_4^{2-}$	$1 \times 10^6$	$\text{Zn}(\text{CN})_4^{2-}$	$4.2 \times 10^{19}$
$\text{Co}(\text{OH})_4^{2-}$	$5 \times 10^9$	$\text{Zn}(\text{NH}_3)_4^{2+}$	$7.8 \times 10^8$
$\text{Cr}(\text{OH})_4^-$	$8.0 \times 10^{29}$	$\text{Zn}(\text{OH})_4^{2-}$	$3 \times 10^{15}$
$\text{Cu}(\text{NH}_3)_4^{2+}$	$5.6 \times 10^{11}$		

**SAMPLE PROBLEM 19.13**

**Calculating the Concentration of a Complex Ion**

**Problem** An industrial chemist converts  $\text{Zn}(\text{H}_2\text{O})_4^{2+}$  to the more stable  $\text{Zn}(\text{NH}_3)_4^{2+}$  ( $K_f = 7.8 \times 10^8$ ) by mixing 50.0 L of 0.0020 M  $\text{Zn}(\text{H}_2\text{O})_4^{2+}$  and 25.0 L of 0.15 M  $\text{NH}_3$ . What is the  $[\text{Zn}(\text{H}_2\text{O})_4^{2+}]$  at equilibrium?

**Plan** We write the complex-ion formation equation and the  $K_f$  expression and use a reaction table to calculate the equilibrium concentrations. To set up the table, we must first find  $[\text{Zn}(\text{H}_2\text{O})_4^{2+}]_{\text{init}}$ . We are given the individual volumes and molar concentrations, so we find the number of moles and divide by the *total* volume because the solutions are mixed. With the large excess of  $\text{NH}_3$  and the high  $K_f$ , we assume that almost all the  $\text{Zn}(\text{H}_2\text{O})_4^{2+}$  is converted to  $\text{Zn}(\text{NH}_3)_4^{2+}$ . Because  $[\text{Zn}(\text{H}_2\text{O})_4^{2+}]$  at equilibrium is very small, we use  $x$  to represent it.

**Solution** Writing the equation and the  $K_f$  expression:

$$K_f = \frac{[\text{Zn}(\text{NH}_3)_4^{2+}]}{[\text{Zn}(\text{H}_2\text{O})_4^{2+}][\text{NH}_3]^4}$$

Finding the initial reactant concentrations:

$$[\text{Zn}(\text{H}_2\text{O})_4^{2+}]_{\text{init}} = \frac{50.0 \text{ L} \times 0.0020 \text{ M}}{50.0 \text{ L} + 25.0 \text{ L}} = 1.3 \times 10^{-3} \text{ M}$$

$$[\text{NH}_3]_{\text{init}} = \frac{25.0 \text{ L} \times 0.15 \text{ M}}{50.0 \text{ L} + 25.0 \text{ L}} = 5.0 \times 10^{-2} \text{ M}$$

Setting up a reaction table: We assume that nearly all the  $\text{Zn}(\text{H}_2\text{O})_4^{2+}$  is converted to  $\text{Zn}(\text{NH}_3)_4^{2+}$ , so we set up the table with  $x = [\text{Zn}(\text{H}_2\text{O})_4^{2+}]$  at equilibrium. Because 4 mol of  $\text{NH}_3$  is needed per mole of  $\text{Zn}(\text{H}_2\text{O})_4^{2+}$ , the change in  $[\text{NH}_3]$  is

$$[\text{NH}_3]_{\text{reacted}} \approx 4(1.3 \times 10^{-3} \text{ M}) = 5.2 \times 10^{-3} \text{ M} \quad \text{and} \quad [\text{Zn}(\text{NH}_3)_4^{2+}] \approx 1.3 \times 10^{-3} \text{ M}$$

Initial	$1.3 \times 10^{-3}$	$5.0 \times 10^{-2}$	0	—
Change	$\sim(-1.3 \times 10^{-3})$	$\sim(-5.2 \times 10^{-3})$	$\sim(+1.3 \times 10^{-3})$	—
Equilibrium	$x$	$4.5 \times 10^{-2}$	$1.3 \times 10^{-3}$	—

Solving for  $x$ , the  $[\text{Zn}(\text{H}_2\text{O})_4^{2+}]$  remaining at equilibrium:

$$K_f = \frac{[\text{Zn}(\text{NH}_3)_4^{2+}]}{[\text{Zn}(\text{H}_2\text{O})_4^{2+}][\text{NH}_3]^4} = 7.8 \times 10^8 \approx \frac{1.3 \times 10^{-3}}{x(4.5 \times 10^{-2})^4}$$

$$x = [\text{Zn}(\text{H}_2\text{O})_4^{2+}] \approx 4.1 \times 10^{-7} \text{ M}$$

**Check** The  $K_f$  is large, so we expect the  $[\text{Zn}(\text{H}_2\text{O})_4^{2+}]$  remaining to be very low.

### FOLLOW-UP PROBLEMS

**19.13A** Cyanide ion is toxic because it forms stable complex ions with the  $\text{Fe}^{3+}$  ion in certain proteins involved in cellular energy production. To study this effect, a biochemist mixes 25.5 mL of  $3.1 \times 10^{-2} \text{ M}$   $\text{Fe}(\text{H}_2\text{O})_6^{3+}$  with 35.0 mL of 1.5 M NaCN. What is the final  $[\text{Fe}(\text{H}_2\text{O})_6^{3+}]$ ? The  $K_f$  of  $\text{Fe}(\text{CN})_6^{3-}$  is  $4.0 \times 10^{43}$ .

**19.13B** The production of aluminum from its ore utilizes a stable complex ion formed from the reaction of  $\text{Al}(\text{H}_2\text{O})_6^{3+}$  with  $\text{F}^-$ . When 2.4 g of  $\text{AlCl}_3$  is dissolved in 250 mL of 0.560 M NaF, what is the final  $[\text{Al}(\text{H}_2\text{O})_6^{3+}]$ ? The  $K_f$  of  $\text{AlF}_6^{3-}$  is  $4 \times 10^{19}$ .

**SOME SIMILAR PROBLEMS** 19.100, 19.101, 19.104, and 19.105

## Complex Ions and the Solubility of Precipitates

In Section 19.3, you saw that  $\text{H}_3\text{O}^+$  increases the solubility of a slightly soluble ionic compound if its anion is that of a weak acid. Similarly, a ligand increases the solubility of a slightly soluble ionic compound if it forms a complex ion with the compound's cation. For example, iron(II) sulfide is very slightly soluble:

When we add some 1.0 M NaCN, the  $\text{CN}^-$  ions act as ligands and react with the small amount of  $\text{Fe}^{2+}(\text{aq})$  to form the complex ion  $\text{Fe}(\text{CN})_6^{4-}$ :

To see the effect of complex-ion formation on the solubility of FeS, we add the equations and, therefore, multiply their equilibrium constants:

The overall dissociation of FeS into ions increased by more than a factor of  $10^{35}$  in the presence of the ligand.

## SAMPLE PROBLEM 19.14

## Calculating the Effect of Complex-Ion Formation on Solubility

Developing an image in “hypo.”

Source: © McGraw-Hill Education/Mark A. Dierker, photographer

**Problem** In black-and-white film developing (*see photo*), excess AgBr is removed from a film negative with “hypo,” an aqueous solution of sodium thiosulfate ( $\text{Na}_2\text{S}_2\text{O}_3$ ), which causes the formation of the complex ion  $\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}$ . Calculate the solubility of AgBr in (a)  $\text{H}_2\text{O}$ ; (b) 1.0 M hypo.  $K_f$  of  $\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}$  is  $4.7 \times 10^{13}$ , and  $K_{sp}$  of AgBr is  $5.0 \times 10^{-13}$ .

**Plan** (a) After writing the dissolution equation and the ion-product expression, we use the given  $K_{sp}$  to solve for  $S$ , the molar solubility of AgBr. (b) In hypo,  $\text{Ag}^+$  forms a complex ion with  $\text{S}_2\text{O}_3^{2-}$ , which shifts the equilibrium and dissolves more AgBr. We write the complex-ion equation and add it to the equation for dissolving AgBr to obtain the overall equation for dissolving AgBr in hypo. We multiply  $K_{sp}$  by  $K_f$  to find  $K_{\text{overall}}$ . To find the solubility of AgBr in hypo, we set up a reaction table, with  $S = [\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}]$ , substitute into the expression for  $K_{\text{overall}}$ , and solve for  $S$ .

**Solution** (a) Solubility in water. Writing the equation for the saturated solution and the ion-product expression:

Solving for solubility ( $S$ ) directly from the equation: We know that

$$S = [\text{AgBr}]_{\text{dissolved}} = [\text{Ag}^+] = [\text{Br}^-]$$

Thus,

$$K_{sp} = [\text{Ag}^+][\text{Br}^-] = S^2 = 5.0 \times 10^{-13}$$

so

$$S = 7.1 \times 10^{-7} \text{ M}$$

(b) Solubility in 1.0 M hypo. Writing the overall equation:

Calculating  $K_{\text{overall}}$ :

$$K_{\text{overall}} = \frac{[\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}][\text{Br}^-]}{[\text{S}_2\text{O}_3^{2-}]^2} = K_{sp} \times K_f = (5.0 \times 10^{-13})(4.7 \times 10^{13}) = 24$$

Setting up a reaction table, with  $S = [\text{AgBr}]_{\text{dissolved}} = [\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}]$ :

Concentration (M)	AgBr(s)	+ 2S <sub>2</sub> O <sub>3</sub> <sup>2-</sup> (aq)	⇌	Ag(S <sub>2</sub> O <sub>3</sub> ) <sub>2</sub> <sup>3-</sup> (aq)	+ Br <sup>-</sup> (aq)
Initial	—	1.0		0	0
Change	—	-2S		+S	+S
Equilibrium	—	1.0 - 2S		S	S

Substituting the values into the expression for  $K_{\text{overall}}$  and solving for  $S$ :

$$K_{\text{overall}} = \frac{[\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}][\text{Br}^-]}{[\text{S}_2\text{O}_3^{2-}]^2} = \frac{S^2}{(1.0 \text{ M} - 2S)^2} = 24$$

Taking the square root of both sides gives

$$\frac{S}{1.0 \text{ M} - 2S} = \sqrt{24} = 4.9 \quad \text{so} \quad S = 4.9 \text{ M} - 9.8S \quad \text{and} \quad 10.8S = 4.9 \text{ M}$$

$$[\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}] = S = 0.45 \text{ M}$$

**Check** (a) From the number of ions in the formula of AgBr, we know that  $S = \sqrt{K_{sp}}$ , so the order of magnitude seems right:  $\sim \sqrt{10^{-14}} \approx 10^{-7}$ . (b) The  $K_{\text{overall}}$  seems correct: the exponents cancel, and  $5 \times 5 = 25$ . Most importantly, the answer makes sense

because the photographic process requires the remaining AgBr to be washed off the film and the large  $K_{\text{overall}}$  confirms that. We can check  $S$  by rounding and working backward to find  $K_{\text{overall}}$ : from the reaction table, we find that

$$[(\text{S}_2\text{O}_3)^{2-}] = 1.0\text{ M} - 2S = 1.0\text{ M} - 2(0.45\text{ M}) = 1.0\text{ M} - 0.90\text{ M} = 0.1\text{ M}$$

so  $K_{\text{overall}} \approx (0.45)^2/(0.1)^2 = 20$ , within rounding of the calculated value.

### FOLLOW-UP PROBLEMS

**19.14A** How does the solubility of AgBr in 1.0 M NH<sub>3</sub> compare with its solubility in 1.0 M hypo, calculated in part (b) of Sample Problem 19.14? The  $K_f$  of Ag(NH<sub>3</sub>)<sub>2</sub><sup>+</sup> is  $1.7 \times 10^7$ .

**19.14B** Calculate the solubility of PbCl<sub>2</sub> in 0.75 M NaOH. The  $K_f$  of Pb(OH)<sub>3</sub><sup>-</sup> is  $8 \times 10^{13}$ , and the  $K_{\text{sp}}$  of PbCl<sub>2</sub> is  $1.7 \times 10^{-5}$ .

**SOME SIMILAR PROBLEMS** 19.102 and 19.103

## Complex Ions of Amphoteric Hydroxides

Many of the same metals that form amphoteric oxides (Chapter 8, p. 354) also form slightly soluble *amphoteric hydroxides*. These compounds dissolve very little in water, but they dissolve to a much greater extent in both acidic and basic solutions. Aluminum hydroxide is one of several examples:

It is insoluble in water ( $K_{\text{sp}} = 3 \times 10^{-34}$ ), but

- It dissolves in acid because H<sub>3</sub>O<sup>+</sup> reacts with the OH<sup>-</sup> anion [Sample Problem 19.9(b)],

giving the overall equation

- It dissolves in base through the formation of a complex ion:

Let's look more closely at this behavior. When we dissolve a soluble aluminum salt, such as Al(NO<sub>3</sub>)<sub>3</sub>, in water and then slowly add a strong base, a white precipitate first forms and then dissolves as more base is added. What reactions are occurring? The formula for the hydrated Al<sup>3+</sup> ion is Al(H<sub>2</sub>O)<sub>6</sub><sup>3+</sup>(aq). It acts as a weak polyprotic acid and reacts with added OH<sup>-</sup> ions in a stepwise manner. In each step, one of the bound H<sub>2</sub>O molecules loses a proton and becomes a bound OH<sup>-</sup> ion, so the number of bound H<sub>2</sub>O molecules is reduced by 1:

After three protons have been removed from each Al(H<sub>2</sub>O)<sub>6</sub><sup>3+</sup>, the white precipitate has formed, which is the insoluble hydroxide Al(H<sub>2</sub>O)<sub>3</sub>(OH)<sub>3</sub>(s), often written more simply as Al(OH)<sub>3</sub>(s). Now you can see that the precipitate actually consists of the hydrated Al<sup>3+</sup> ion with an H<sup>+</sup> removed from each of three bound H<sub>2</sub>O molecules (Figure 19.19, *next page, center*). Addition of H<sub>3</sub>O<sup>+</sup> protonates the OH<sup>-</sup> ions and reforms the hydrated Al<sup>3+</sup> ion (Figure 19.19, *left*).

Further addition of OH<sup>-</sup> removes a fourth H<sup>+</sup> and the precipitate dissolves as the soluble ion Al(H<sub>2</sub>O)<sub>2</sub>(OH)<sub>4</sub><sup>-</sup>(aq) forms (Figure 19.19, *right*), which we usually write with the formula Al(OH)<sub>4</sub><sup>-</sup>(aq):

In other words, this complex ion is not created by ligands substituting for bound water molecules but through an acid-base reaction in which added OH<sup>-</sup> ions titrate bound water molecules.

**Figure 19.19** The amphoteric behavior of aluminum hydroxide. When solid  $\text{Al}(\text{OH})_3$  is treated with  $\text{H}_3\text{O}^+$  (left) or with  $\text{OH}^-$  (right), it dissolves as a result of the formation of soluble complex ions.

Several other slightly soluble hydroxides, including those of cadmium, chromium(III), cobalt(III), lead(II), tin(II), and zinc, are amphoteric and exhibit similar reactions:

In contrast, the slightly soluble hydroxides of iron(II), iron(III), and calcium dissolve in acid, but do *not* dissolve in base, because the three remaining bound water molecules are not acidic enough to lose any of their protons:

This difference in solubility in base between  $\text{Al}(\text{OH})_3$  and  $\text{Fe}(\text{OH})_3$  is the key to an important separation step in the production of aluminum metal, so we'll consider it again in Section 22.4.

### › Summary of Section 19.4

- › A complex ion consists of a central metal ion covalently bonded to two or more negatively charged or neutral ligands. Its formation is characterized by a formation constant,  $K_f$ .
- › A hydrated metal ion is a complex ion with water molecules as ligands. Other ligands (stronger Lewis bases) can displace the water molecules in a stepwise process. In most cases, the  $K_f$  value for each step is large, so the fully substituted complex ion forms almost completely in the presence of excess ligand.
- › Adding a solution containing a ligand increases the solubility of an ionic precipitate if the cation forms a complex ion with the ligand.
- › Amphoteric metal hydroxides dissolve in acid and base due to reactions that involve complex ions.

## CHAPTER REVIEW GUIDE

### Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

#### Understand These Concepts

- How the presence of a common ion suppresses a reaction that forms it (§19.1)
- Why the concentrations of buffer components must be high to minimize the change in pH due to addition of small amounts of  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$  (§19.1)
- How buffer capacity depends on buffer concentration and on the  $\text{p}K_a$  of the acid component; why buffer range is within  $\pm 1$  pH unit of the  $\text{p}K_a$  (§19.1)
- Why the shapes of strong acid–strong base, weak acid–strong base, and weak base–strong acid titration curves differ (§19.2)
- How the pH at the equivalence point is determined by the species present; why the pH at the midpoint of the buffer region equals the  $\text{p}K_a$  of the acid (§19.2)
- The nature of an acid-base indicator as a conjugate acid-base pair with differently colored acidic and basic forms (§19.2)
- The distinction between equivalence point and end point in an acid-base titration (§19.2)
- How the titration curve of a polyprotic acid has a buffer region and equivalence point for each ionizable proton (§19.2)
- How a slightly soluble ionic compound reaches equilibrium in water, expressed by an equilibrium (solubility-product) constant,  $K_{\text{sp}}$  (§19.3)
- Why incomplete dissociation of an ionic compound means that calculated values for  $K_{\text{sp}}$  and solubility are approximations (§19.3)
- Why a common ion in a solution decreases the solubility of its compounds (§19.3)
- How pH affects the solubility of a compound that contains a weak-acid anion (§19.3)
- How precipitate formation depends on the relative values of  $Q_{\text{sp}}$  and  $K_{\text{sp}}$  (§19.3)
- How selective precipitation and simultaneous equilibria are used to separate ions (§19.3)
- How complex-ion formation occurs in steps and is characterized by an overall equilibrium (formation) constant,  $K_f$  (§19.4)

- Why addition of a ligand increases the solubility of a compound whose metal ion forms a complex ion (§19.4)
- How the aqueous chemistry of amphoteric hydroxides involves precipitation, complex-ion formation, and acid-base equilibria (§19.4)

#### Master These Skills

- Using stoichiometry and equilibrium problem-solving techniques to calculate the effect of added  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$  on buffer pH (SP 19.1)
- Using the Henderson-Hasselbalch equation to calculate buffer pH (§19.1)
- Using molecular scenes to examine buffers (SP 19.2)
- Choosing the components for a buffer with a given pH and calculating their quantities (SP 19.3)
- Calculating the pH at any point in an acid-base titration (§19.2 and SP 19.4)
- Choosing an appropriate indicator based on the pH at various points in a titration (§19.2)
- Writing  $K_{\text{sp}}$  expressions for slightly soluble ionic compounds (SP 19.5)
- Calculating a  $K_{\text{sp}}$  value from solubility data (SP 19.6)
- Calculating solubility from a  $K_{\text{sp}}$  value (SP 19.7)
- Using  $K_{\text{sp}}$  values to compare solubilities for compounds with the same total number of ions (§19.3)
- Calculating the decrease in solubility caused by the presence of a common ion (SP 19.8)
- Predicting the effect of added  $\text{H}_3\text{O}^+$  on solubility (SP 19.9)
- Using ion concentrations to calculate  $Q_{\text{sp}}$  and compare it with  $K_{\text{sp}}$  to predict whether a precipitate forms (SPs 19.10, 19.11)
- Comparing  $K_{\text{sp}}$  values in order to separate ions by selective precipitation (SP 19.12)
- Calculating the equilibrium concentration of a hydrated metal ion after addition of excess ligand forms a complex ion (SP 19.13)
- Using an overall equilibrium constant ( $K_{\text{sp}} \times K_f$ ) to calculate the effect of complex-ion formation on solubility (SP 19.14)

### Key Terms

Page numbers appear in parentheses.

acid-base buffer (843)

acid-base titration curve (853)

buffer capacity (849)

buffer range (849)

common-ion effect (844)

complex ion (877)

end point (861)

equivalence point (854)

formation constant ( $K_f$ ) (877)

Henderson-Hasselbalch equation (849)

ligand (877)

selective precipitation (874)

solubility-product

constant ( $K_{\text{sp}}$ ) (864)

### Key Equations and Relationships

Page numbers appear in parentheses.

**19.1** Finding the pH from known concentrations of a conjugate acid-base pair (Henderson-Hasselbalch equation) (849):

$$\text{pH} = \text{p}K_a + \log \left( \frac{[\text{base}]}{[\text{acid}]} \right)$$

**19.2** Defining the equilibrium condition for a saturated solution of a slightly soluble compound,  $\text{M}_p\text{X}_q$ , composed of  $\text{M}^{n+}$  and  $\text{X}^{z-}$  ions (864):

$$Q_{\text{sp}} = [\text{M}^{n+}]^p [\text{X}^{z-}]^q = K_{\text{sp}}$$

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

**19.1A** (a) Before addition:

Assuming  $x$  is small enough to be neglected,

$$[\text{HF}] = 0.50 \text{ M} \quad \text{and} \quad [\text{F}^-] = 0.45 \text{ M}$$

$$[\text{H}_3\text{O}^+] = K_a \times \frac{[\text{HF}]}{[\text{F}^-]} \approx (6.8 \times 10^{-4}) \left( \frac{0.50}{0.45} \right) = 7.6 \times 10^{-4} \text{ M}$$

$$\text{pH} = 3.12$$

(b) After addition of 0.40 g of NaOH to 1.0 L of buffer: Since 0.40 g of NaOH = 0.010 mol, we have

Concentration (M)	HF(aq)	+	OH <sup>-</sup> (aq)	→	F <sup>-</sup> (aq)	+	H <sub>2</sub> O(l)
Initial	0.50		0.010		0.45		—
Change	-0.010		-0.010		+0.010		—
Equilibrium	0.49		0		0.46		—

$$[\text{HF}] = 0.49 \text{ M} \quad \text{and} \quad [\text{F}^-] = 0.46 \text{ M}$$

$$[\text{H}_3\text{O}^+] \approx (6.8 \times 10^{-4}) \left( \frac{0.49}{0.46} \right) = 7.2 \times 10^{-4} \text{ M}; \text{pH} = 3.14$$

**19.1B** (a) Before addition:

$$K_b \text{ of } (\text{CH}_3)_2\text{NH} = 10^{-\text{p}K_b} = 10^{-3.23} = 5.9 \times 10^{-4}$$

$$K_a \text{ of } (\text{CH}_3)_2\text{NH}_2^+ = \frac{K_w}{K_b \text{ of } (\text{CH}_3)_2\text{NH}} = \frac{1.0 \times 10^{-14}}{5.9 \times 10^{-4}} = 1.7 \times 10^{-11}$$

$$[(\text{CH}_3)_2\text{NH}_2^+] = 0.25 \text{ M} \quad \text{and} \quad [(\text{CH}_3)_2\text{NH}] = 0.30 \text{ M}$$

$$[\text{H}_3\text{O}^+] = K_a \times \frac{[(\text{CH}_3)_2\text{NH}_2^+]}{[(\text{CH}_3)_2\text{NH}]} \approx (1.7 \times 10^{-11}) \left( \frac{0.25}{0.30} \right)$$

$$= 1.4 \times 10^{-11} \text{ M}$$

$$\text{pH} = 10.85$$

(b) After addition of 50.0 mL of 0.75 M HCl to 1.0 L of buffer:

$$[(\text{CH}_3)_2\text{NH}_2^+]_{\text{init}} = \frac{M_{\text{conc}} \times V_{\text{conc}}}{V_{\text{dil}}} = \frac{0.25 \text{ M} \times 1.0 \text{ L}}{1.05 \text{ L}} = 0.24 \text{ M}$$

$$\text{Similarly, } [(\text{CH}_3)_2\text{NH}] = 0.29 \text{ M} \quad \text{and} \quad [\text{H}_3\text{O}^+] = 0.036 \text{ M}$$

$$[\text{H}_3\text{O}^+] \approx (1.7 \times 10^{-11}) \left( \frac{0.28}{0.25} \right) = 1.9 \times 10^{-11} \text{ M}; \text{pH} = 10.72$$

**19.2A** (a) There are more HB molecules than B<sup>-</sup> ions. Strong base would convert HB to B<sup>-</sup>, thereby making the ratio closer to 1.

(b) Enough strong base is added to convert three HB molecules to three B<sup>-</sup> ions, resulting in a buffer with four acid molecules and four conjugate base ions:

**19.2B** (a)  $\text{pH} = \text{p}K_a + \log \left( \frac{[\text{A}^-]}{[\text{HA}]} \right)$ , and sample 3 has  $\frac{[\text{A}^-]}{[\text{HA}]} = \frac{6}{3} = 2$ ;  $\frac{[\text{A}^-]}{[\text{HA}]} > 1$  results in  $\text{pH} > \text{p}K_a$

(b) Added strong base reacts with the acid HA; sample 2 has the largest concentration of HA.

(c)  $\text{pH}$  of buffer =  $\text{p}K_a \pm 1 = 4.2 \pm 1$ , so the buffer  $\text{pH}$  range is 3.2–5.2; the acid-base pair HA/A<sup>-</sup> is not suitable for preparing a buffer with a  $\text{pH}$  of 6.1.

**19.3A**  $\text{p}K_a = -\log K_a = -\log (6.3 \times 10^{-5}) = 4.20$

$$\text{pH} = \text{p}K_a + \log \left( \frac{[\text{C}_6\text{H}_5\text{COO}^-]}{[\text{C}_6\text{H}_5\text{COOH}]} \right)$$

$$4.25 = 4.20 + \log \left( \frac{[\text{C}_6\text{H}_5\text{COO}^-]}{[\text{C}_6\text{H}_5\text{COOH}]} \right)$$

$$\left( \frac{[\text{C}_6\text{H}_5\text{COO}^-]}{[\text{C}_6\text{H}_5\text{COOH}]} \right) = 1.1$$

Amount (mol) C<sub>6</sub>H<sub>5</sub>COOH

$$= 5.0 \text{ L soln} \times \frac{0.050 \text{ mol C}_6\text{H}_5\text{COO}^-}{1 \text{ L soln}} \times \frac{1.0 \text{ mol C}_6\text{H}_5\text{COOH}}{1.1 \text{ mol C}_6\text{H}_5\text{COO}^-}$$

$$= 0.23 \text{ mol C}_6\text{H}_5\text{COOH}$$

Mass (g) of C<sub>6</sub>H<sub>5</sub>COOH

$$= 0.23 \text{ mol C}_6\text{H}_5\text{COOH} \times \frac{122.12 \text{ g C}_6\text{H}_5\text{COOH}}{1 \text{ mol C}_6\text{H}_5\text{COOH}}$$

$$= 28 \text{ g C}_6\text{H}_5\text{COOH}$$

Dissolve 28 g of C<sub>6</sub>H<sub>5</sub>COOH into about 4.8 L of 0.050 M

C<sub>6</sub>H<sub>5</sub>COONa and add more 0.050 M C<sub>6</sub>H<sub>5</sub>COONa for a total volume of 5.0 L. Add strong acid or base dropwise as needed.

**19.3B**  $K_a \text{ of } \text{NH}_4^+ = \frac{K_w}{K_b \text{ of } \text{NH}_3} = \frac{1.0 \times 10^{-14}}{1.76 \times 10^{-5}} = 5.68 \times 10^{-10}$

$$\text{p}K_a = -\log (5.68 \times 10^{-10}) = 9.25$$

$$\text{pH} = \text{p}K_a + \log \left( \frac{[\text{NH}_3]}{[\text{NH}_4^+]}\right)$$

$$9.18 = 9.25 + \log \left( \frac{[\text{NH}_3]}{[\text{NH}_4^+]}\right)$$

$$\left( \frac{[\text{NH}_3]}{[\text{NH}_4^+]}\right) = 0.85 \text{ (buffer-component concentration ratio)}$$

$$\begin{aligned} \text{Mass of NH}_4\text{Cl} &= 0.75 \text{ L soln} \times \frac{0.15 \text{ mol NH}_3}{1 \text{ L soln}} \\ &\times \frac{1 \text{ mol NH}_4\text{Cl}}{0.85 \text{ mol NH}_3} \times \frac{53.49 \text{ g NH}_4\text{Cl}}{1 \text{ mol NH}_4\text{Cl}} \\ &= 7.1 \text{ g NH}_4\text{Cl} \end{aligned}$$

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{Br}^-]}{[\text{HBrO}]} = 2.3 \times 10^{-9} \approx \frac{(x)(x)}{0.2000}$$

$$x \approx [\text{H}_3\text{O}^+] \approx \sqrt{(2.3 \times 10^{-9})(0.2000)} = 2.1 \times 10^{-5} M$$

$$\text{pH} = 4.68$$

(b) When  $[\text{HBrO}] = [\text{BrO}^-]$ ,  $[\text{HBrO}]/[\text{BrO}^-] = 1$ :

$$\text{pH} = \text{p}K_a + \log \frac{[\text{BrO}^-]}{[\text{HBrO}]} = 8.64 + \log 1 = 8.64$$

(c) Initial amount (mol) of  $\text{HBrO} = 0.02000 \text{ L} \times 0.2000 M = 0.004000 \text{ mol}$

Amount (mol) of added  $\text{NaOH}$  at the equivalence point =  $0.004000 \text{ mol}$

Volume (L) of added  $\text{NaOH} = 0.004000 \text{ mol} \times 1 \text{ L}/0.1000 \text{ mol} = 0.04000 \text{ L}$

From the reaction table, there are  $0.004000 \text{ mol}$  of  $\text{BrO}^-$  at the equivalence point.

$$[\text{BrO}^-] = \frac{\text{amount (mol) of } \text{BrO}^-}{\text{total volume (L)}} = \frac{0.004000 \text{ mol}}{0.02000 \text{ L} + 0.04000 \text{ L}} = 0.06667 M$$

$$K_b \text{ of } \text{BrO}^- = \frac{K_w}{K_a \text{ of } \text{HBrO}} = \frac{1.0 \times 10^{-14}}{2.3 \times 10^{-9}} = 4.3 \times 10^{-6}$$

$$K_b = \frac{[\text{HBrO}][\text{OH}^-]}{[\text{BrO}^-]} = 4.3 \times 10^{-6} = \frac{(x)(x)}{0.06667}$$

$$x = [\text{OH}^-] = \sqrt{(4.3 \times 10^{-6})(0.06667)} = 5.3 \times 10^{-4} M$$

$$[\text{H}_3\text{O}^+] = 1.9 \times 10^{-11} M; \text{pH} = 10.72$$

(d) Amount (mol) of  $\text{OH}^-$  added =  $2 \times 0.004000 \text{ mol} = 0.008000 \text{ mol}$

Volume (L) of  $\text{OH}^-$  soln =  $0.008000 \text{ mol} \times 1 \text{ L}/0.1000 \text{ mol} = 0.08000 \text{ L}$

$$[\text{OH}^-] = \frac{\text{amount (mol) of } \text{OH}^- \text{ unreacted}}{\text{total volume (L)}} = \frac{0.008000 \text{ mol} - 0.004000 \text{ mol}}{(0.02000 + 0.08000) \text{ L}} = 0.04000 M$$

$$[\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{0.04000} = 2.5 \times 10^{-13} M$$

$$\text{pH} = 12.60$$

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{C}_6\text{H}_5\text{COO}^-]}{[\text{C}_6\text{H}_5\text{COOH}]} = 6.3 \times 10^{-5} \approx \frac{(x)(x)}{0.1000}$$

$$x \approx [\text{H}_3\text{O}^+] \approx \sqrt{(6.3 \times 10^{-5})(0.1000)} = 2.5 \times 10^{-3} M$$

$$\text{pH} = 2.60$$

(b) Initial amount (mol) of  $\text{C}_6\text{H}_5\text{COOH} = 0.03000 \text{ L} \times 0.1000 M = 0.003000 \text{ mol}$

Amount (mol) of added  $\text{NaOH} = 0.01200 \text{ L} \times 0.1500 M = 0.001800 \text{ mol}$

From the reaction table,  $0.003000 \text{ mol} - 0.001800 \text{ mol} = 0.001200 \text{ mol}$  of  $\text{C}_6\text{H}_5\text{COOH}$  remains and  $0.001800 \text{ mol}$  of  $\text{C}_6\text{H}_5\text{COO}^-$  is produced:

$$\text{pH} = \text{p}K_a + \log \frac{[\text{C}_6\text{H}_5\text{COO}^-]}{[\text{C}_6\text{H}_5\text{COOH}]} = 4.20 + \log \frac{0.001800 \text{ mol}}{0.001200 \text{ mol}} = 4.38$$

(c) Initial amount (mol) of  $\text{C}_6\text{H}_5\text{COOH} = 0.03000 \text{ L} \times 0.1000 M = 0.003000 \text{ mol}$

Amount (mol) of added  $\text{NaOH}$  at the equivalence point =  $0.003000 \text{ mol}$

Volume (L) of added  $\text{NaOH} = 0.003000 \text{ mol} \times 1 \text{ L}/0.1500 \text{ mol} = 0.02000 \text{ L}$

From the reaction table,  $0.003000 \text{ mol}$  of  $\text{C}_6\text{H}_5\text{COO}^-$  is present at the equivalence point.

$$[\text{C}_6\text{H}_5\text{COO}^-] = \frac{\text{amount (mol) of } \text{C}_6\text{H}_5\text{COO}^-}{\text{total volume (L)}} = \frac{0.003000 \text{ mol}}{0.03000 \text{ L} + 0.02000 \text{ L}} = 0.06000 M$$

$$K_b \text{ of } \text{C}_6\text{H}_5\text{COO}^- = \frac{K_w}{K_a \text{ of } \text{C}_6\text{H}_5\text{COOH}} = \frac{1.0 \times 10^{-14}}{6.3 \times 10^{-5}} = 1.6 \times 10^{-10}$$

$$K_b = \frac{[\text{C}_6\text{H}_5\text{COOH}][\text{OH}^-]}{[\text{C}_6\text{H}_5\text{COO}^-]} = 1.6 \times 10^{-10} = \frac{(x)(x)}{0.06000}$$

$$x = [\text{OH}^-] = \sqrt{(1.6 \times 10^{-10})(0.06000)} = 3.1 \times 10^{-6} M$$

$$[\text{H}_3\text{O}^+] = 3.2 \times 10^{-9} M; \text{pH} = 8.49$$

(d) Amount (mol) of  $\text{OH}^-$  added =  $0.02200 \text{ L} \times 0.1500 M = 0.003300 \text{ mol}$

$$[\text{OH}^-] = \frac{\text{amount (mol) of } \text{OH}^- \text{ unreacted}}{\text{total volume (L)}} = \frac{0.003300 \text{ mol} - 0.003000 \text{ mol}}{(0.03000 + 0.02200) \text{ L}} = 0.00577 M$$

$$[\text{H}_3\text{O}^+] = \frac{K_w}{[\text{OH}^-]} = 1.73 \times 10^{-12} M$$

$$\text{pH} = 11.76 \text{ (pH is shown to two decimal places)}$$

**19.5B** (a)  $\text{PbCrO}_4$ , lead(II) chromate; (b)  $\text{FeS}$ , iron(II) sulfide; (c)  $\text{SrF}_2$ , strontium fluoride; (d)  $\text{Cu}_3(\text{PO}_4)_2$ , copper(II) phosphate

$$\text{19.6A } [\text{CaF}_2] = \frac{1.5 \times 10^{-4} \text{ g CaF}_2}{10.0 \text{ mL soln}} \times \frac{1000 \text{ mL}}{1 \text{ L}} \times \frac{1 \text{ mol CaF}_2}{78.08 \text{ g CaF}_2} = 1.9 \times 10^{-4} M$$

$$[\text{Ca}^{2+}] = 1.9 \times 10^{-4} M \text{ and } [\text{F}^-] = 2(1.9 \times 10^{-4} M) = 3.8 \times 10^{-4} M$$

$$K_{sp} = [\text{Ca}^{2+}][\text{F}^-]^2 = (1.9 \times 10^{-4})(3.8 \times 10^{-4})^2 = 2.7 \times 10^{-11}$$

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

(continued)

$$\begin{aligned} \mathbf{19.6B} \quad [\text{Ag}_3\text{PO}_4] &= \frac{3.2 \times 10^{-4} \text{ g Ag}_3\text{PO}_4}{50. \text{ mL soln}} \times \frac{1000 \text{ mL}}{1 \text{ L}} \\ &\quad \times \frac{1 \text{ mol Ag}_3\text{PO}_4}{418.7 \text{ g Ag}_3\text{PO}_4} \\ &= 1.5 \times 10^{-5} \text{ M} \end{aligned}$$

$$[\text{Ag}^+] = 3(1.5 \times 10^{-5} \text{ M}) = 4.5 \times 10^{-5} \text{ M} \quad \text{and} \quad [\text{PO}_4^{3-}] = 1.5 \times 10^{-5} \text{ M}$$

$$K_{\text{sp}} = [\text{Ag}^+]^3[\text{PO}_4^{3-}] = (4.5 \times 10^{-5})^3(1.5 \times 10^{-5}) = 1.4 \times 10^{-18}$$

**19.7A** From the reaction table,  $[\text{Mg}^{2+}] = S$  and  $[\text{OH}^-] = 2S$ .  
 $K_{\text{sp}} = [\text{Mg}^{2+}][\text{OH}^-]^2 = [S][2S]^2 = 4S^3 = 6.3 \times 10^{-10}$ ;  $S = 5.4 \times 10^{-4} \text{ M}$

**19.7B** From the reaction table,  $[\text{Ca}^{2+}] = 3S$  and  $[\text{PO}_4^{3-}] = 2S$ .  
 $K_{\text{sp}} = [\text{Ca}^{2+}]^3[\text{PO}_4^{3-}]^2 = (3S)^3(2S)^2 = 27S^3 \times 4S^2 = 108S^5 = 1.2 \times 10^{-29}$   
 $S = 6.4 \times 10^{-7} \text{ M}$

**19.8A** (a) In water:  $K_{\text{sp}} = [\text{Ba}^{2+}][\text{SO}_4^{2-}] = (S)(S) = S^2 = 1.1 \times 10^{-10}$   
 $S = 1.0 \times 10^{-5} \text{ M}$

(b) In 0.10 M  $\text{Na}_2\text{SO}_4$ :  $[\text{SO}_4^{2-}] = 0.10 \text{ M}$  from  $\text{Na}_2\text{SO}_4$ ;  
 $[\text{SO}_4^{2-}] = S$  from  $\text{BaSO}_4$

Assume  $S + 0.10 \text{ M} \approx 0.10 \text{ M}$

$$K_{\text{sp}} = 1.1 \times 10^{-10} \approx S \times 0.10$$
;  $S = 1.1 \times 10^{-9} \text{ M}$

$S$  decreases in presence of the common ion  $[\text{SO}_4^{2-}]$ .

**19.8B** (a) In water:  $K_{\text{sp}} = [\text{Ca}^{2+}][\text{F}^-]^2 = (S)(2S)^2 = 4S^3 = 3.2 \times 10^{-11}$   
 $S = 2.0 \times 10^{-4} \text{ M}$

(b) In 0.20 M  $\text{CaCl}_2$ :  $[\text{Ca}^{2+}]$  from  $\text{CaCl}_2 = 0.20 \text{ M}$ ;  
 $[\text{Ca}^{2+}]$  from  $\text{CaF}_2 = S$

Assume  $S + 0.20 \text{ M} \approx 0.20 \text{ M}$

$$K_{\text{sp}} = 3.2 \times 10^{-11} \approx 0.20 \times (2S)^2$$
;  $S = 6.3 \times 10^{-6} \text{ M}$

(c) In 0.20 M  $\text{NiF}_2$ :  $[\text{F}^-]$  from  $\text{NiF}_2 = 2(0.20) = 0.40 \text{ M}$ ;  
 $[\text{F}^-]$  from  $\text{CaF}_2 = 2S$

Assume  $2S + 0.40 \text{ M} \approx 0.40 \text{ M}$

$$K_{\text{sp}} = 3.2 \times 10^{-11} \approx S \times (0.40)^2$$
;  $S = 2.0 \times 10^{-10} \text{ M}$

**19.9A** (a) Increases solubility.

(b) Increases solubility.

(c) No effect.  $\text{I}^-(aq)$  is the conjugate base of strong acid  $\text{HI}$ .

**19.9B** (a) Increases solubility.

(b) No effect.  $\text{Cl}^-$  is the conjugate base of strong acid  $\text{HCl}$ .

(c) Increases solubility.

$$\begin{aligned} Q_{\text{sp}} &= [\text{Ca}^{2+}]^3[\text{PO}_4^{3-}]^2 = (1.0 \times 10^{-9})^3(1.0 \times 10^{-9})^2 \\ &= (1.0 \times 10^{-9})^5 = 1.0 \times 10^{-45} \end{aligned}$$

$Q_{\text{sp}} < K_{\text{sp}}$ , so  $\text{Ca}_3(\text{PO}_4)_2$  will not precipitate.

$$\begin{aligned} \text{Amount (mol) of Pb}^{2+} &= 25 \text{ L} \times \frac{0.015 \text{ g Pb}^{2+}}{1.0 \text{ L}} \times \frac{1 \text{ mol Pb}^{2+}}{207.2 \text{ g Pb}^{2+}} \\ &= 1.8 \times 10^{-3} \text{ mol} \end{aligned}$$

$$[\text{Pb}^{2+}] = \frac{1.8 \times 10^{-3} \text{ mol Pb}^{2+}}{25 \text{ L} + 0.500 \text{ L}} = 7.1 \times 10^{-5} \text{ M}$$

Amount (mol) of  $\text{S}^{2-} = 0.10 \text{ M S}^{2-} \times 0.500 \text{ L} = 0.050 \text{ mol}$

$$[\text{S}^{2-}] = \frac{0.050 \text{ mol}}{25 \text{ L} + 0.500 \text{ L}} = 2.0 \times 10^{-3} \text{ M}$$

$$Q_{\text{sp}} = [\text{Pb}^{2+}][\text{S}^{2-}] = (7.1 \times 10^{-5})(2.0 \times 10^{-3}) = 1.4 \times 10^{-7}$$

$Q_{\text{sp}} > K_{\text{sp}}$  (which is  $3 \times 10^{-25}$ ), so  $\text{PbS}$  will precipitate.

**19.11A** (a) Scene 3 has the same relative numbers of ions as in the compound's formula (ratio of 1  $\text{Ni}^{2+}$  to every 2  $\text{OH}^-$ ).

(b) Based on  $\text{Ni}(\text{OH})_2(s) \rightleftharpoons \text{Ni}^{2+}(aq) + 2\text{OH}^-(aq)$  and  $Q_{\text{sp}} = [\text{Ni}^{2+}][\text{OH}^-]^2$ , the ion products are (3)(4)<sup>2</sup> = 48 in scene 1; (4)(2)<sup>2</sup> = 16 in scene 2; and (2)(4)<sup>2</sup> = 32 =  $K_{\text{sp}}$  in scene 3. Since  $Q_{\text{sp}}$  for scene 1 exceeds  $K_{\text{sp}}$  for scene 3, more solid forms.

(c) Addition of acid will decrease the mass of  $\text{Ni}(\text{OH})_2(s)$  by reacting with  $\text{OH}^-$ , thereby causing more solid to dissolve; addition of base will increase the mass of  $\text{Ni}(\text{OH})_2(s)$  due to the common-ion effect.

**19.11B** (a) Scene 1 has the same relative numbers of ions as in the compound's formula (ratio of 1  $\text{Pb}^{2+}$  to every 2  $\text{Cl}^-$ ).

(b) Based on  $\text{PbCl}_2(s) \rightleftharpoons \text{Pb}^{2+}(aq) + 2\text{Cl}^-(aq)$  and  $Q_{\text{sp}} = [\text{Pb}^{2+}][\text{Cl}^-]^2$ , the ion products are (3)(6)<sup>2</sup> = 108 =  $K_{\text{sp}}$  in scene 1; (4)(5)<sup>2</sup> = 100 in scene 2; and (5)(5)<sup>2</sup> = 125 in scene 3. Since  $Q_{\text{sp}}$  for scene 3 exceeds  $K_{\text{sp}}$  for scene 1, more solid forms.

(c) Addition of  $\text{HCl}(aq)$  will increase the mass of  $\text{PbCl}_2$  due to the common-ion effect ( $\text{Cl}^-$  is the common ion).

**19.12A** Both salts have 1/1 ion ratios, and  $K_{\text{sp}}$  values show that  $\text{CaSO}_4$  is more soluble:

$$[\text{SO}_4^{2-}] = \frac{K_{\text{sp}}}{[\text{Ca}^{2+}]} = \frac{2.4 \times 10^{-5}}{0.025} = 9.6 \times 10^{-4} \text{ M}$$

**19.12B** Both salts have 1/2 ion ratios, and  $K_{\text{sp}}$  values show that  $\text{BaF}_2$  is more soluble:

$$[\text{F}^-] = \sqrt{\frac{K_{\text{sp}}}{[\text{Ba}^{2+}]}} = \sqrt{\frac{1.5 \times 10^{-6}}{0.020 \text{ M}}} = 8.7 \times 10^{-3} \text{ M}$$

$$\begin{aligned} \mathbf{19.13A} \quad [\text{Fe}(\text{H}_2\text{O})_6^{3+}]_{\text{init}} &= \frac{(0.0255 \text{ L})(3.1 \times 10^{-2} \text{ M})}{0.0255 \text{ L} + 0.0350 \text{ L}} \\ &= 1.3 \times 10^{-2} \text{ M} \end{aligned}$$

Similarly,  $[\text{CN}^-]_{\text{init}} = 0.87 \text{ M}$ . From the reaction table,

Concentration (M)	$\text{Fe}(\text{H}_2\text{O})_6^{3+}(aq)$	+ $6\text{CN}^-(aq)$	$\rightleftharpoons$	$\text{Fe}(\text{CN})_6^{3-}(aq)$	+ $6\text{H}_2\text{O}(l)$
Initial	$1.3 \times 10^{-2}$	0.87		0	—
Change	$\sim(-1.3 \times 10^{-2})$	$\sim(-6 \times [1.3 \times 10^{-2}])$		$\sim(+1.3 \times 10^{-2})$	—
Equilibrium	$x$	0.79		$1.3 \times 10^{-2}$	—

$$K_f = \frac{[\text{Fe}(\text{CN})_6^{3-}]}{[\text{Fe}(\text{H}_2\text{O})_6^{3+}][\text{CN}^-]^6} = 4.0 \times 10^{43} \approx \frac{1.3 \times 10^{-2}}{x(0.79)^6}$$

$$x = [\text{Fe}(\text{H}_2\text{O})_6^{3+}] \approx 1.3 \times 10^{-45} \text{ M}$$

$$\mathbf{19.13B} \quad [\text{Al}(\text{H}_2\text{O})_6^{3+}]_{\text{init}} = \frac{2.4 \text{ g AlCl}_3 \times \frac{1 \text{ mol AlCl}_3}{133.33 \text{ g AlCl}_3}}{0.250 \text{ L}} = 0.072 \text{ M}$$

$$[\text{F}^-]_{\text{init}} = 0.560 \text{ M}$$

$$K_f = \frac{[\text{AlF}_6^{3-}]}{[\text{Al}(\text{H}_2\text{O})_6^{3+}][\text{F}^-]^6} = 4 \times 10^{19} \approx \frac{0.072}{x(0.128)^6}$$

$$x = [\text{Al}(\text{H}_2\text{O})_6^{3+}] \approx 4 \times 10^{-16} \text{ M}$$

$$K_{\text{overall}} = K_{\text{sp}} \text{ of AgBr} \times K_f \text{ of Ag}(\text{NH}_3)_2^+ = 8.5 \times 10^{-6}$$

From the reaction table,  $[\text{NH}_3] = 1.0 - 2S$  and  $[\text{Ag}(\text{NH}_3)_2^+] = [\text{Br}^-] = S$ .

$$K_{\text{overall}} = \frac{[\text{Ag}(\text{NH}_3)_2^+][\text{Br}^-]}{[\text{NH}_3]^2} = 8.5 \times 10^{-6} = \frac{[S][S]}{(1.0 - 2S)^2}$$

$$\frac{S}{1.0 - 2S} = \sqrt{8.5 \times 10^{-6}} = 2.9 \times 10^{-3}$$

$$S = [\text{Ag}(\text{NH}_3)_2^+] = 2.9 \times 10^{-3} \text{ M}$$

Solubility is greater in 1.0 M hypo than in 1.0 M  $\text{NH}_3$ .

$$K_{\text{overall}} = K_{\text{sp}} \times K_f = 1 \times 10^9$$

From the reaction table,  $[\text{OH}^-] = 0.75 - 3S$  and  $[\text{Pb}(\text{OH})_3^-] = S$ ;  $[\text{Cl}^-] = 2S$ .

$$K_{\text{overall}} = \frac{[\text{Pb}(\text{OH})_3^-][\text{Cl}^-]^2}{[\text{OH}^-]^3} = 1 \times 10^9 = \frac{(S)(2S)^2}{(0.75 - 3S)^3}$$

$$= \frac{4S^3}{(0.75 - 3S)^3}$$

$$\frac{\sqrt[3]{4S}}{0.75 - 3S} = \sqrt[3]{1 \times 10^9}$$

$$S = [\text{Pb}(\text{OH})_3^-] = 0.25 \text{ M}$$

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

**Note:** Unless stated otherwise, all of the problems for this chapter refer to aqueous solutions at 298 K (25°C).

### Equilibria of Acid-Base Buffers

(Sample Problems 19.1 to 19.3)

#### Concept Review Questions

- 19.1** What is the purpose of an acid-base buffer?
- 19.2** How do the acid and base components of a buffer function? Why are they often the conjugate acid-base pair of a weak acid?
- 19.3** What is the common-ion effect? How is it related to Le Châtelier's principle? Explain with equations that include HF and NaF.
- 19.4** What is the difference between buffers with high and low capacities? Will adding 0.01 mol of HCl produce a greater pH change in a buffer with a high or a low capacity? Explain.
- 19.5** Which of these factors influence buffer capacity? How?
- (a) The identity of the conjugate acid-base pair

- (b) pH of the buffer
- (c) Concentration of buffer components
- (d) Buffer range
- (e)  $\text{p}K_a$  of the acid component

**19.6** What is the relationship between the buffer range and the buffer-component concentration ratio?

**19.7** A chemist needs a pH 3.5 buffer. Should she use NaOH with formic acid ( $K_a = 1.8 \times 10^{-4}$ ) or with acetic acid ( $K_a = 1.8 \times 10^{-5}$ )? Why? What is the disadvantage of choosing the other acid? What is the role of the NaOH?

**19.8** State and explain the relative change in the pH and in the buffer-component concentration ratio,  $[\text{NaA}]/[\text{HA}]$ , for each of the following additions:

- (a) Add 0.1 M NaOH to the buffer
- (b) Add 0.1 M HCl to the buffer
- (c) Dissolve pure NaA in the buffer
- (d) Dissolve pure HA in the buffer

**19.9** Does the pH increase or decrease with each of the following additions, and does it do so to a large or small extent in each case?

- (a) 5 drops of 0.1 M NaOH to 100 mL of 0.5 M acetate buffer
- (b) 5 drops of 0.1 M HCl to 100 mL of 0.5 M acetate buffer
- (c) 5 drops of 0.1 M NaOH to 100 mL of 0.5 M HCl
- (d) 5 drops of 0.1 M NaOH to distilled water

**Skill-Building Exercises (grouped in similar pairs)**

**19.10** The scenes below depict solutions of the same HA/A<sup>-</sup> buffer (HA is red and blue and A<sup>-</sup> is red; other ions and water molecules have been omitted for clarity). (a) Which solution has the greatest buffer capacity? (b) Explain how the pH ranges of the buffers compare. (c) Which solution can react with the largest amount of added strong acid?

**19.11** The scenes below show three samples of a buffer consisting of HA and A<sup>-</sup> (HA is green and blue and A<sup>-</sup> is green; other ions and water are not shown). (a) Which buffer can react with the largest amount of added strong base? (b) Which buffer has the highest pH? (c) Which buffer has pH = pK<sub>a</sub>?

**19.12** What are the [H<sub>3</sub>O<sup>+</sup>] and the pH of a propanoic acid–propanoate buffer that consists of 0.35 M CH<sub>3</sub>CH<sub>2</sub>COONa and 0.15 M CH<sub>3</sub>CH<sub>2</sub>COOH (K<sub>a</sub> of propanoic acid = 1.3 × 10<sup>-5</sup>)?

**19.13** What are the [H<sub>3</sub>O<sup>+</sup>] and the pH of a benzoic acid–benzoate buffer that consists of 0.33 M C<sub>6</sub>H<sub>5</sub>COOH and 0.28 M C<sub>6</sub>H<sub>5</sub>COONa (K<sub>a</sub> of benzoic acid = 6.3 × 10<sup>-5</sup>)?

**19.14** What are the [H<sub>3</sub>O<sup>+</sup>] and the pH of a buffer that consists of 0.55 M HNO<sub>2</sub> and 0.75 M KNO<sub>2</sub> (K<sub>a</sub> of HNO<sub>2</sub> = 7.1 × 10<sup>-4</sup>)?

**19.15** What are the [H<sub>3</sub>O<sup>+</sup>] and the pH of a buffer that consists of 0.20 M HF and 0.25 M KF (K<sub>a</sub> of HF = 6.8 × 10<sup>-4</sup>)?

**19.16** Find the pH of a buffer that consists of 0.45 M HCOOH and 0.63 M HCOONa (pK<sub>a</sub> of HCOOH = 3.74).

**19.17** Find the pH of a buffer that consists of 0.95 M HBrO and 0.68 M KBrO (pK<sub>a</sub> of HBrO = 8.64).

**19.18** Find the pH of a buffer that consists of 1.3 M sodium phenolate (C<sub>6</sub>H<sub>5</sub>ONa) and 1.2 M phenol (C<sub>6</sub>H<sub>5</sub>OH) (pK<sub>a</sub> of phenol = 10.00).

**19.19** Find the pH of a buffer that consists of 0.12 M boric acid (H<sub>3</sub>BO<sub>3</sub>) and 0.82 M sodium borate (NaH<sub>2</sub>BO<sub>3</sub>) (pK<sub>a</sub> of boric acid = 9.24).

**19.20** Find the pH of a buffer that consists of 0.25 M NH<sub>3</sub> and 0.15 M NH<sub>4</sub>Cl (pK<sub>b</sub> of NH<sub>3</sub> = 4.75).

**19.21** Find the pH of a buffer that consists of 0.50 M methylamine (CH<sub>3</sub>NH<sub>2</sub>) and 0.60 M CH<sub>3</sub>NH<sub>3</sub>Cl (pK<sub>b</sub> of CH<sub>3</sub>NH<sub>2</sub> = 3.35).

**19.22** A buffer consists of 0.22 M KHCO<sub>3</sub> and 0.37 M K<sub>2</sub>CO<sub>3</sub>. Carbonic acid is a diprotic acid with K<sub>a1</sub> = 4.5 × 10<sup>-7</sup> and K<sub>a2</sub> = 4.7 × 10<sup>-11</sup>. (a) Which K<sub>a</sub> value is more important to this buffer? (b) What is the buffer pH?

**19.23** A buffer consists of 0.50 M NaH<sub>2</sub>PO<sub>4</sub> and 0.40 M Na<sub>2</sub>HPO<sub>4</sub>. Phosphoric acid is a triprotic acid (K<sub>a1</sub> = 7.2 × 10<sup>-3</sup>, K<sub>a2</sub> = 6.3 × 10<sup>-8</sup>, and K<sub>a3</sub> = 4.2 × 10<sup>-13</sup>). (a) Which K<sub>a</sub> value is most important to this buffer? (b) What is the buffer pH?

**19.24** What is the component concentration ratio, [Pr<sup>-</sup>]/[HPr], of a buffer that has a pH of 5.44 (K<sub>a</sub> of HPr = 1.3 × 10<sup>-5</sup>)?

**19.25** What is the component concentration ratio, [NO<sub>2</sub><sup>-</sup>]/[HNO<sub>2</sub>], of a buffer that has a pH of 2.95 (K<sub>a</sub> of HNO<sub>2</sub> = 7.1 × 10<sup>-4</sup>)?

**19.26** What is the component concentration ratio, [BrO<sup>-</sup>]/[HBrO], of a buffer that has a pH of 7.95 (K<sub>a</sub> of HBrO = 2.3 × 10<sup>-9</sup>)?

**19.27** What is the component concentration ratio, [CH<sub>3</sub>COO<sup>-</sup>]/[CH<sub>3</sub>COOH], of a buffer that has a pH of 4.39 (K<sub>a</sub> of CH<sub>3</sub>COOH = 1.8 × 10<sup>-5</sup>)?

**19.28** A buffer containing 0.2000 M of acid, HA, and 0.1500 M of its conjugate base, A<sup>-</sup>, has a pH of 3.35. What is the pH after 0.0015 mol of NaOH is added to 0.5000 L of this solution?

**19.29** A buffer that contains 0.40 M of a base, B, and 0.25 M of its conjugate acid, BH<sup>+</sup>, has a pH of 8.88. What is the pH after 0.0020 mol of HCl is added to 0.25 L of this solution?

**19.30** A buffer that contains 0.110 M HY and 0.220 M Y<sup>-</sup> has a pH of 8.77. What is the pH after 0.0015 mol of Ba(OH)<sub>2</sub> is added to 0.350 L of this solution?

**19.31** A buffer that contains 1.05 M B and 0.750 M BH<sup>+</sup> has a pH of 9.50. What is the pH after 0.0050 mol of HCl is added to 0.500 L of this solution?

**19.32** A buffer is prepared by mixing 204 mL of 0.452 M HCl and 0.500 L of 0.400 M sodium acetate. (See Appendix C.) (a) What is the pH? (b) How many grams of KOH must be added to 0.500 L of the buffer to change the pH by 0.15 units?

**19.33** A buffer is prepared by mixing 50.0 mL of 0.050 M sodium bicarbonate and 10.7 mL of 0.10 M NaOH. (See Appendix C.) (a) What is the pH? (b) How many grams of HCl must be added to 25.0 mL of the buffer to change the pH by 0.07 units?

**19.34** Choose specific acid–base conjugate pairs to make the following buffers: (a) pH ≈ 4.5; (b) pH ≈ 7.0. (See Appendix C.)

**19.35** Choose specific acid–base conjugate pairs to make the following buffers: (a) [H<sub>3</sub>O<sup>+</sup>] ≈ 1 × 10<sup>-9</sup> M; (b) [OH<sup>-</sup>] ≈ 3 × 10<sup>-5</sup> M. (See Appendix C.)

**19.36** Choose specific acid–base conjugate pairs to make the following buffers: (a) pH ≈ 3.5; (b) pH ≈ 5.5. (See Appendix C.)

**19.37** Choose specific acid–base conjugate pairs to make the following buffers: (a) [OH<sup>-</sup>] ≈ 1 × 10<sup>-6</sup> M; (b) [H<sub>3</sub>O<sup>+</sup>] ≈ 4 × 10<sup>-4</sup> M. (See Appendix C.)

**Problems in Context**

**19.38** An industrial chemist studying bleaching and sterilizing prepares several hypochlorite buffers. Find the pH of (a) 0.100 M HClO and 0.100 M NaClO; (b) 0.100 M HClO and 0.150 M NaClO; (c) 0.150 M HClO and 0.100 M NaClO; (d) 1.0 L of the solution in part (a) after 0.0050 mol of NaOH has been added.

**19.39** Oxoanions of phosphorus are buffer components in blood. For a KH<sub>2</sub>PO<sub>4</sub>/Na<sub>2</sub>HPO<sub>4</sub> buffer with pH = 7.40 (pH of normal arterial blood), what is the buffer–component concentration ratio?

**Acid-Base Titration Curves**

(Sample Problem 19.4)

**Concept Review Questions**

**19.40** The scenes below depict the relative concentrations of  $\text{H}_3\text{PO}_4$ ,  $\text{H}_2\text{PO}_4^-$ , and  $\text{HPO}_4^{2-}$  during a titration with aqueous NaOH, but they are out of order. (Phosphate groups are *purple*, hydrogens are *blue*, and  $\text{Na}^+$  ions and water molecules are not shown.) (a) List the scenes in the correct order. (b) What is the pH in the correctly ordered second scene (see Appendix C)? (c) If it requires 10.00 mL of the NaOH solution to reach this scene, how much more is needed to reach the last scene?

**19.41** Explain how *strong acid*–strong base, *weak acid*–strong base, and *weak base*–strong acid titrations using the same concentrations differ in terms of (a) the initial pH and (b) the pH at the equivalence point. (The component in *italics* is in the flask.)

**19.42** What species are in the buffer region of a weak acid–strong base titration? How are they different from the species at the equivalence point? How are they different from the species in the buffer region of a weak base–strong acid titration?

**19.43** Why is the midpoint of the buffer region of a weak acid–strong base titration significant?

**19.44** How can you estimate the pH range of an indicator's color change? Why do some indicators have two separate pH ranges?

**19.45** Why does the color change of an indicator take place over a range of about 2 pH units?

**19.46** Why doesn't the addition of an acid-base indicator affect the pH of a test solution?

**19.47** What is the difference between the end point of a titration and the equivalence point? Is the equivalence point always reached first? Explain.

**19.48** How does the titration curve of a monoprotic acid differ from that of a diprotic acid?

**Skill-Building Exercises (grouped in similar pairs)**

**19.49** Calculate the pH during the titration of 40.00 mL of 0.1000 M HCl with 0.1000 M NaOH solution after each of the following additions of base:

- (a) 0 mL      (b) 25.00 mL      (c) 39.00 mL      (d) 39.90 mL  
(e) 40.00 mL      (f) 40.10 mL      (g) 50.00 mL

**19.50** Calculate the pH during the titration of 30.00 mL of 0.1000 M KOH with 0.1000 M HBr solution after each of the following additions of acid:

- (a) 0 mL      (b) 15.00 mL      (c) 29.00 mL      (d) 29.90 mL  
(e) 30.00 mL      (f) 30.10 mL      (g) 40.00 mL

**19.51** Find the pH during the titration of 20.00 mL of 0.1000 M butanoic acid,  $\text{CH}_3\text{CH}_2\text{CH}_2\text{COOH}$  ( $K_a = 1.54 \times 10^{-5}$ ), with 0.1000 M NaOH solution after the following additions of titrant:

- (a) 0 mL      (b) 10.00 mL      (c) 15.00 mL      (d) 19.00 mL  
(e) 19.95 mL      (f) 20.00 mL      (g) 20.05 mL      (h) 25.00 mL

**19.52** Find the pH during the titration of 20.00 mL of 0.1000 M triethylamine,  $(\text{CH}_3\text{CH}_2)_3\text{N}$  ( $K_b = 5.2 \times 10^{-4}$ ), with 0.1000 M HCl solution after the following additions of titrant:

- (a) 0 mL      (b) 10.00 mL      (c) 15.00 mL      (d) 19.00 mL  
(e) 19.95 mL      (f) 20.00 mL      (g) 20.05 mL      (h) 25.00 mL

**19.53** Find the pH of the equivalence point(s) and the volume (mL) of 0.0372 M NaOH needed to reach the point(s) in titrations of

- (a) 42.2 mL of 0.0520 M  $\text{CH}_3\text{COOH}$   
(b) 28.9 mL of 0.0850 M  $\text{H}_2\text{SO}_3$  (two equivalence points)

**19.54** Find the pH of the equivalence point(s) and the volume (mL) of 0.0588 M KOH needed to reach the point(s) in titrations of

- (a) 23.4 mL of 0.0390 M  $\text{HNO}_2$   
(b) 17.3 mL of 0.130 M  $\text{H}_2\text{CO}_3$  (two equivalence points)

**19.55** Find the pH of the equivalence point(s) and the volume (mL) of 0.125 M HCl needed to reach the point(s) in titrations of

- (a) 65.5 mL of 0.234 M  $\text{NH}_3$   
(b) 21.8 mL of 1.11 M  $\text{CH}_3\text{NH}_2$

**19.56** Find the pH of the equivalence point(s) and the volume (mL) of 0.447 M  $\text{HNO}_3$  needed to reach the point(s) in titrations of

- (a) 2.65 L of 0.0750 M pyridine ( $\text{C}_5\text{H}_5\text{N}$ )  
(b) 0.188 L of 0.250 M ethylenediamine ( $\text{H}_2\text{NCH}_2\text{CH}_2\text{NH}_2$ )

**19.57** The indicator cresol red has  $K_a = 3.5 \times 10^{-9}$ . Over what approximate pH range does it change color?

**19.58** The indicator ethyl red has  $K_a = 3.8 \times 10^{-6}$ . Over what approximate pH range does it change color?

**19.59** Use Figure 19.9 to find an indicator for these titrations:

- (a) 0.10 M HCl with 0.10 M NaOH  
(b) 0.10 M  $\text{HCOOH}$  (see Appendix C) with 0.10 M NaOH

**19.60** Use Figure 19.9 to find an indicator for these titrations:

- (a) 0.10 M  $\text{CH}_3\text{NH}_2$  (see Appendix C) with 0.10 M HCl  
(b) 0.50 M HI with 0.10 M KOH

**19.61** Use Figure 19.9 to find an indicator for these titrations:

- (a) 0.5 M  $(\text{CH}_3)_2\text{NH}$  (see Appendix C) with 0.5 M HBr  
(b) 0.2 M KOH with 0.2 M  $\text{HNO}_3$

**19.62** Use Figure 19.9 to find an indicator for these titrations:

- (a) 0.25 M  $\text{C}_6\text{H}_5\text{COOH}$  (see Appendix C) with 0.25 M KOH  
(b) 0.50 M  $\text{NH}_4\text{Cl}$  (see Appendix C) with 0.50 M NaOH

**Equilibria of Slightly Soluble Ionic Compounds**

(Sample Problems 19.5 to 19.12)

**Concept Review Questions**

**19.63** The molar solubility ( $S$ ) of  $\text{M}_2\text{X}$  is  $5 \times 10^{-5}$  M. Find  $S$  of each ion. How do you set up the calculation to find  $K_{sp}$ ? What assumption must you make about the dissociation of  $\text{M}_2\text{X}$  into ions? Why is the calculated  $K_{sp}$  higher than the actual value?

**19.64** Why does pH affect the solubility of  $\text{BaF}_2$  but not of  $\text{BaCl}_2$ ?

**19.65** A list of  $K_{sp}$  values like that in Appendix C can be used to compare the solubility of silver chloride directly with that of silver bromide but not with that of silver chromate. Explain.

**19.66** In a gaseous equilibrium, the reverse reaction occurs when  $Q_c > K_c$ . What occurs in aqueous solution when  $Q_{sp} > K_{sp}$ ?

**Skill-Building Exercises (grouped in similar pairs)**

**19.67** Write the ion-product expressions for (a) silver carbonate; (b) barium fluoride; (c) copper(II) sulfide.

**19.68** Write the ion-product expressions for (a) iron(III) hydroxide; (b) barium phosphate; (c) magnesium fluoride.

**19.69** Write the ion-product expressions for (a) calcium chromate; (b) silver cyanide; (c) silver phosphate.

**19.70** Write the ion-product expressions for (a) lead(II) iodide; (b) strontium sulfate; (c) chromium(III) hydroxide.

**19.71** The solubility of silver carbonate is 0.032 *M* at 20°C. Calculate its  $K_{sp}$ .

**19.72** The solubility of zinc oxalate is  $7.9 \times 10^{-3}$  *M* at 18°C. Calculate its  $K_{sp}$ .

**19.73** The solubility of silver dichromate at 15°C is  $8.3 \times 10^{-3}$  g/100. mL solution. Calculate its  $K_{sp}$ .

**19.74** The solubility of calcium sulfate at 30°C is 0.209 g/100. mL solution. Calculate its  $K_{sp}$ .

**19.75** Find the molar solubility of  $\text{SrCO}_3$  ( $K_{sp} = 5.4 \times 10^{-10}$ ) in (a) pure water and (b) 0.13 *M*  $\text{Sr}(\text{NO}_3)_2$ .

**19.76** Find the molar solubility of  $\text{BaCrO}_4$  ( $K_{sp} = 2.1 \times 10^{-10}$ ) in (a) pure water and (b)  $1.5 \times 10^{-3}$  *M*  $\text{Na}_2\text{CrO}_4$ .

**19.77** Calculate the molar solubility of  $\text{Ca}(\text{IO}_3)_2$  in (a) 0.060 *M*  $\text{Ca}(\text{NO}_3)_2$  and (b) 0.060 *M*  $\text{NaIO}_3$ . (See Appendix C.)

**19.78** Calculate the molar solubility of  $\text{Ag}_2\text{SO}_4$  in (a) 0.22 *M*  $\text{AgNO}_3$  and (b) 0.22 *M*  $\text{Na}_2\text{SO}_4$ . (See Appendix C.)

**19.79** Which compound in each pair is more soluble in water?

- (a) Magnesium hydroxide or nickel(II) hydroxide
- (b) Lead(II) sulfide or copper(II) sulfide
- (c) Silver sulfate or magnesium fluoride

**19.80** Which compound in each pair is more soluble in water?

- (a) Strontium sulfate or barium chromate
- (b) Calcium carbonate or copper(II) carbonate
- (c) Barium iodate or silver chromate

**19.81** Which compound in each pair is more soluble in water?

- (a) Barium sulfate or calcium sulfate
- (b) Calcium phosphate or magnesium phosphate
- (c) Silver chloride or lead(II) sulfide

**19.82** Which compound in each pair is more soluble in water?

- (a) Manganese(II) hydroxide or calcium iodate
- (b) Strontium carbonate or cadmium sulfide
- (c) Silver cyanide or copper(I) iodide

**19.83** Write equations to show whether the solubility of either of the following is affected by pH: (a)  $\text{AgCl}$ ; (b)  $\text{SrCO}_3$ .

**19.84** Write equations to show whether the solubility of either of the following is affected by pH: (a)  $\text{CuBr}$ ; (b)  $\text{Ca}_3(\text{PO}_4)_2$ .

**19.85** Write equations to show whether the solubility of either of the following is affected by pH: (a)  $\text{Fe}(\text{OH})_2$ ; (b)  $\text{CuS}$ .

**19.86** Write equations to show whether the solubility of either of the following is affected by pH: (a)  $\text{PbI}_2$ ; (b)  $\text{Hg}_2(\text{CN})_2$ .

**19.87** Does any solid  $\text{Cu}(\text{OH})_2$  form when 0.075 g of  $\text{KOH}$  is dissolved in 1.0 L of  $1.0 \times 10^{-3}$  *M*  $\text{Cu}(\text{NO}_3)_2$ ?

**19.88** Does any solid  $\text{PbCl}_2$  form when 3.5 mg of  $\text{NaCl}$  is dissolved in 0.250 L of 0.12 *M*  $\text{Pb}(\text{NO}_3)_2$ ?

**19.89** Does any solid  $\text{Ba}(\text{IO}_3)_2$  form when 7.5 mg of  $\text{BaCl}_2$  is dissolved in 500. mL of 0.023 *M*  $\text{NaIO}_3$ ?

**19.90** Does any solid  $\text{Ag}_2\text{CrO}_4$  form when  $2.7 \times 10^{-5}$  g of  $\text{AgNO}_3$  is dissolved in 15.0 mL of  $4.0 \times 10^{-4}$  *M*  $\text{K}_2\text{CrO}_4$ ?

**Problems in Context**

**19.91** When blood is donated, sodium oxalate solution is used to precipitate  $\text{Ca}^{2+}$ , which triggers clotting. A 104-mL sample of blood contains  $9.7 \times 10^{-5}$  g  $\text{Ca}^{2+}/\text{mL}$ . A technologist treats the sample with 100.0 mL of 0.1550 *M*  $\text{Na}_2\text{C}_2\text{O}_4$ . Calculate  $[\text{Ca}^{2+}]$  after the treatment. (See Appendix C for  $K_{sp}$  of  $\text{CaC}_2\text{O}_4 \cdot \text{H}_2\text{O}$ .)

**19.92** A 50.0-mL volume of 0.50 *M*  $\text{Fe}(\text{NO}_3)_3$  is mixed with 125 mL of 0.25 *M*  $\text{Cd}(\text{NO}_3)_2$ .

(a) If aqueous  $\text{NaOH}$  is added, which ion precipitates first? (See Appendix C.)

(b) Describe how the metal ions can be separated using  $\text{NaOH}$ .

(c) Calculate the  $[\text{OH}^-]$  that will accomplish the separation.

**Equilibria Involving Complex Ions**

(Sample Problems 19.13 and 19.14)

**Concept Review Questions**

**19.93** How can a metal cation be at the center of a complex anion?

**19.94** Write equations to demonstrate the stepwise reaction of  $\text{Cd}(\text{H}_2\text{O})_4^{2+}$  in an aqueous solution of  $\text{KI}$  to form  $\text{CdI}_4^{2-}$ .

Show that  $K_{f(\text{overall})} = K_{f1} \times K_{f2} \times K_{f3} \times K_{f4}$ .

**19.95** Consider the dissolution of  $\text{Zn}(\text{OH})_2$  in water:

Adding aqueous  $\text{NaOH}$  causes more  $\text{Zn}(\text{OH})_2$  to dissolve. Does this violate Le Châtelier's principle? Explain.

**Skill-Building Exercises (grouped in similar pairs)**

**19.96** Write a balanced equation for the reaction of  $\text{Hg}(\text{H}_2\text{O})_4^{2+}$  in aqueous  $\text{KCN}$ .

**19.97** Write a balanced equation for the reaction of  $\text{Zn}(\text{H}_2\text{O})_4^{2+}$  in aqueous  $\text{NaCN}$ .

**19.98** Write a balanced equation for the reaction of  $\text{Ag}(\text{H}_2\text{O})_2^+$  in aqueous  $\text{Na}_2\text{S}_2\text{O}_3$ .

**19.99** Write a balanced equation for the reaction of  $\text{Al}(\text{H}_2\text{O})_6^{3+}$  in aqueous  $\text{KF}$ .

**19.100** What is  $[\text{Ag}^+]$  when 25.0 mL each of 0.044 *M*  $\text{AgNO}_3$  and 0.57 *M*  $\text{Na}_2\text{S}_2\text{O}_3$  are mixed? [ $K_f$  of  $\text{Ag}(\text{S}_2\text{O}_3)_2^{3-} = 4.7 \times 10^{13}$ ]

**19.101** Potassium thiocyanate,  $\text{KSCN}$ , is often used to detect the presence of  $\text{Fe}^{3+}$  ions in solution through the formation of the red  $\text{Fe}(\text{H}_2\text{O})_5\text{SCN}^{2+}$  (or, more simply,  $\text{FeSCN}^{2+}$ ;  $K_f = 8.9 \times 10^2$ ). What is  $[\text{Fe}^{3+}]$  when 0.50 L each of 0.0015 *M*  $\text{Fe}(\text{NO}_3)_3$  and 0.20 *M*  $\text{KSCN}$  are mixed?

**19.102** Find the solubility of  $\text{Cr}(\text{OH})_3$  in a buffer of pH 13.0 [ $K_{sp}$  of  $\text{Cr}(\text{OH})_3 = 6.3 \times 10^{-31}$ ;  $K_f$  of  $\text{Cr}(\text{OH})_4^- = 8.0 \times 10^{29}$ ].

**19.103** Find the solubility of  $\text{AgI}$  in 2.5 *M*  $\text{NH}_3$  [ $K_{sp}$  of  $\text{AgI} = 8.3 \times 10^{-17}$ ;  $K_f$  of  $\text{Ag}(\text{NH}_3)_2^+ = 1.7 \times 10^7$ ].

**19.104** When 0.84 g of  $\text{ZnCl}_2$  is dissolved in 245 mL of 0.150 *M*  $\text{NaCN}$ , what are  $[\text{Zn}^{2+}]$ ,  $[\text{Zn}(\text{CN})_4^{2-}]$ , and  $[\text{CN}^-]$  [ $K_f$  of  $\text{Zn}(\text{CN})_4^{2-} = 4.2 \times 10^{19}$ ]

**19.105** When 2.4 g of  $\text{Co}(\text{NO}_3)_2$  is dissolved in 0.350 L of 0.22 M KOH, what are  $[\text{Co}^{2+}]$ ,  $[\text{Co}(\text{OH})_4^{2-}]$ , and  $[\text{OH}^-]$  [ $K_f$  of  $\text{Co}(\text{OH})_4^{2-} = 5 \times 10^9$ ]?

### Comprehensive Problems

**19.106** What volumes of 0.200 M HCOOH and 2.00 M NaOH would make 500. mL of a buffer with the same pH as a buffer made from 475 mL of 0.200 M benzoic acid and 25 mL of 2.00 M NaOH?

**19.107** A microbiologist is preparing a medium on which to culture *E. coli* bacteria. She buffers the medium at pH 7.00 to minimize the effect of acid-producing fermentation. What volumes of equimolar aqueous solutions of  $\text{K}_2\text{HPO}_4$  and  $\text{KH}_2\text{PO}_4$  must she combine to make 100. mL of the pH 7.00 buffer?

**19.108** As an FDA physiologist, you need 0.700 L of formic acid-formate buffer with a pH of 3.74. (a) What is the required buffer-component concentration ratio? (b) How do you prepare this solution from stock solutions of 1.0 M HCOOH and 1.0 M NaOH? (c) What is the final concentration of HCOOH in this solution?

**19.109** Tris(hydroxymethyl)aminomethane [ $(\text{HOCH}_2)_3\text{CNH}_2$ ], known as TRIS, is a weak base used in biochemical experiments to make buffer solutions in the pH range of 7 to 9. A certain TRIS buffer has a pH of 8.10 at 25°C and a pH of 7.80 at 37°C. Why does the pH change with temperature?

**19.110** Water flowing through pipes of carbon steel must be kept at pH 5 or greater to limit corrosion. If an  $8.0 \times 10^3$  lb/h water stream contains 10 ppm sulfuric acid and 0.015% acetic acid, how many pounds per hour of sodium acetate trihydrate must be added to maintain that pH?

**19.111** Gout is caused by an error in metabolism that leads to a buildup of uric acid in body fluids, which is deposited as slightly soluble sodium urate ( $\text{C}_5\text{H}_3\text{N}_4\text{O}_3\text{Na}$ ) in the joints. If the extracellular  $[\text{Na}^+]$  is 0.15 M and the solubility of sodium urate is 0.085 g/100. mL, what is the minimum urate ion concentration (abbreviated  $[\text{Ur}^-]$ ) that will cause a deposit of sodium urate?

**19.112** In the process of cave formation (Section 19.3), the dissolution of  $\text{CO}_2$  (equation 1) has a  $K_{\text{eq}}$  of  $3.1 \times 10^{-2}$ , and the formation of aqueous  $\text{Ca}(\text{HCO}_3)_2$  (equation 2) has a  $K_{\text{eq}}$  of  $1 \times 10^{-12}$ . The fraction by volume of atmospheric  $\text{CO}_2$  is  $4 \times 10^{-4}$ . (a) Find  $[\text{CO}_2(\text{aq})]$  in equilibrium with atmospheric  $\text{CO}_2$ . (b) Determine  $[\text{Ca}^{2+}]$  arising from (equation 2) given current levels of atmospheric  $\text{CO}_2$ . (c) Calculate  $[\text{Ca}^{2+}]$  if atmospheric  $\text{CO}_2$  doubles.

**19.113** Phosphate systems form essential buffers in organisms. Calculate the pH of a buffer made by dissolving 0.80 mol of NaOH in 0.50 L of 1.0 M  $\text{H}_3\text{PO}_4$ .

**19.114** The solubility of KCl is 3.7 M at 20°C. Two beakers each contain 100. mL of saturated KCl solution: 100. mL of 6.0 M HCl is added to the first beaker and 100. mL of 12 M HCl is added to the second. (a) Find the ion-product constant for KCl at 20°C. (b) What mass, if any, of KCl will precipitate from each beaker?

**19.115** It is possible to detect  $\text{NH}_3$  gas over  $10^{-2}$  M  $\text{NH}_3$ . To what pH must 0.15 M  $\text{NH}_4\text{Cl}$  be raised to form detectable  $\text{NH}_3$ ?

**19.116** Manganese(II) sulfide is one of the compounds found in the nodules on the ocean floor that may eventually be a primary source of many transition metals. The solubility of MnS is  $4.7 \times 10^{-4}$  g/100. mL solution. Estimate the  $K_{\text{sp}}$  of MnS.

**19.117** The normal pH of blood is  $7.40 \pm 0.05$  and is controlled in part by the  $\text{H}_2\text{CO}_3/\text{HCO}_3^-$  buffer system.

(a) Assuming that the  $K_a$  value for carbonic acid at 25°C applies to blood, what is the  $[\text{H}_2\text{CO}_3]/[\text{HCO}_3^-]$  ratio in normal blood?

(b) In a condition called *acidosis*, the blood is too acidic. What is the  $[\text{H}_2\text{CO}_3]/[\text{HCO}_3^-]$  ratio in a patient whose blood pH is 7.20?

**19.118** A bioengineer preparing cells for cloning bathes a small piece of rat epithelial tissue in a TRIS buffer (see Problem 19.109). The buffer is made by dissolving 43.0 g of TRIS ( $\text{p}K_b = 5.91$ ) in enough 0.095 M HCl to make 1.00 L of solution. What are the molarity of TRIS and the pH of the buffer?

**19.119** Sketch a qualitative curve for the titration of ethylenediamine,  $\text{H}_2\text{NCH}_2\text{CH}_2\text{NH}_2$ , with 0.1 M HCl.

**19.120** Amino acids [general formula  $\text{NH}_2\text{CH}(\text{R})\text{COOH}$ ] can be considered polyprotic acids. In many cases, the R group contains additional amine and carboxyl groups.

(a) Can an amino acid dissolved in pure water have a protonated COOH group and an unprotonated  $\text{NH}_2$  group ( $K_a$  of COOH group =  $4.47 \times 10^{-3}$ ;  $K_b$  of  $\text{NH}_2$  group =  $6.03 \times 10^{-5}$ )? Use glycine,  $\text{NH}_2\text{CH}_2\text{COOH}$ , to explain why.

(b) Calculate  $[\text{NH}_3\text{CH}_2\text{COO}^-]/[\text{NH}_3\text{CH}_2\text{COOH}]$  at pH 5.5.

(c) The R group of lysine is  $-\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_2$  ( $\text{p}K_b = 3.47$ ). Draw the structure of lysine at pH 1, physiological pH ( $\sim 7$ ), and pH 13.

(d) The R group of glutamic acid is  $-\text{CH}_2\text{CH}_2\text{COOH}$  ( $\text{p}K_a = 4.07$ ). Of the forms of glutamic acid that are shown below, which predominates at (1) pH 1, (2) physiological pH ( $\sim 7$ ), and (3) pH 13?

**19.121** The scene at right depicts a saturated solution of  $\text{MCl}_2(\text{s})$  in the presence of dilute aqueous NaCl; each sphere represents  $1.0 \times 10^{-6}$  mol of ion, and the volume is 250.0 mL (solid  $\text{MCl}_2$  is shown as green chunks,  $\text{M}^{2+}$  is blue, and  $\text{Cl}^-$  is yellow;  $\text{Na}^+$  ions and water molecules are not shown). (a) Calculate the  $K_{\text{sp}}$  of  $\text{MCl}_2$ . (b) If  $\text{M}(\text{NO}_3)_2(\text{s})$  is added, is there an increase, decrease, or no change in the number of  $\text{Cl}^-$  particles? In the  $K_{\text{sp}}$ ? In the mass of  $\text{MCl}_2(\text{s})$ ?

**19.122** Tooth enamel consists of hydroxyapatite,  $\text{Ca}_5(\text{PO}_4)_3\text{OH}$  ( $K_{\text{sp}} = 6.8 \times 10^{-37}$ ). Fluoride ion added to drinking water reacts with  $\text{Ca}_5(\text{PO}_4)_3\text{OH}$  to form the more tooth decay-resistant fluorapatite,  $\text{Ca}_5(\text{PO}_4)_3\text{F}$  ( $K_{\text{sp}} = 1.0 \times 10^{-60}$ ). Fluoridated water has dramatically decreased cavities among children. Calculate the solubility of  $\text{Ca}_5(\text{PO}_4)_3\text{OH}$  and of  $\text{Ca}_5(\text{PO}_4)_3\text{F}$  in water.

**19.123** The acid-base indicator ethyl orange turns from red to yellow over the pH range 3.4 to 4.8. Estimate  $K_a$  for ethyl orange.

**19.124** Use the values obtained in Problem 19.49 to sketch a curve of  $[\text{H}_3\text{O}^+]$  vs. mL of added titrant. Are there advantages or disadvantages to viewing the results in this form? Explain.

**19.125** Instrumental acid-base titrations use a pH meter to monitor the changes in pH and volume. The equivalence point is found from the volume at which the curve has the steepest slope.

(a) Use the data in Figure 19.6 to calculate the slope ( $\Delta\text{pH}/\Delta V$ ) for all pairs of adjacent points and to calculate the average volume ( $V_{\text{avg}}$ ) for each interval.

(b) Plot  $\Delta\text{pH}/\Delta V$  vs.  $V_{\text{avg}}$  to find the steepest slope, and thus the volume at the equivalence point. (For example, the first pair of points gives  $\Delta\text{pH} = 0.22$ ,  $\Delta V = 10.00$  mL; hence,  $\Delta\text{pH}/\Delta V = 0.022$  mL<sup>-1</sup>, and  $V_{\text{avg}} = 5.00$  mL.)

**19.126** What is the pH of a solution of  $6.5 \times 10^{-9}$  mol of  $\text{Ca}(\text{OH})_2$  in 10.0 L of water [ $K_{\text{sp}}$  of  $\text{Ca}(\text{OH})_2 = 6.5 \times 10^{-6}$ ]?

**19.127** Muscle physiologists study the accumulation of lactic acid [ $\text{CH}_3\text{CH}(\text{OH})\text{COOH}$ ] during exercise. Food chemists study its occurrence in sour milk, beer, wine, and fruit. Industrial microbiologists study its formation by various bacterial species from carbohydrates. A biochemist prepares a lactic acid–lactate buffer by mixing 225 mL of 0.85 M lactic acid ( $K_{\text{a}} = 1.38 \times 10^{-4}$ ) with 435 mL of 0.68 M sodium lactate. What is the buffer pH?

**19.128** A student wants to dissolve the maximum amount of  $\text{CaF}_2$  ( $K_{\text{sp}} = 3.2 \times 10^{-11}$ ) to make 1 L of aqueous solution.

(a) Into which of the following solvents should she dissolve the salt?

- (i) Pure water                      (ii) 0.01 M HF  
(iii) 0.01 M NaOH                (iv) 0.01 M HCl  
(v) 0.01 M  $\text{Ca}(\text{OH})_2$

(b) Which would dissolve the least amount of salt?

**19.129** A 500.-mL solution consists of 0.050 mol of solid NaOH and 0.13 mol of hypochlorous acid ( $\text{HClO}$ ;  $K_{\text{a}} = 3.0 \times 10^{-8}$ ) dissolved in water.

(a) Aside from water, what is the concentration of each species that is present?

(b) What is the pH of the solution?

(c) What is the pH after adding 0.0050 mol of HCl to the flask?

**19.130** Calcium ion present in water supplies is easily precipitated as calcite ( $\text{CaCO}_3$ ):

Because the  $K_{\text{sp}}$  decreases with temperature, heating hard water forms a calcite “scale,” which clogs pipes and water heaters. Find the solubility of calcite in water (a) at 10°C ( $K_{\text{sp}} = 4.4 \times 10^{-9}$ ) and (b) at 30°C ( $K_{\text{sp}} = 3.1 \times 10^{-9}$ ).

**19.131** Calculate the molar solubility of  $\text{Hg}_2\text{C}_2\text{O}_4$  ( $K_{\text{sp}} = 1.75 \times 10^{-13}$ ) in 0.13 M  $\text{Hg}_2(\text{NO}_3)_2$ .

**19.132** Environmental engineers use alkalinity as a measure of the capacity of carbonate buffering systems in water samples:

$$\text{Alkalinity (mol/L)} = [\text{HCO}_3^-] + 2[\text{CO}_3^{2-}] + [\text{OH}^-] - [\text{H}^+]$$

Find the alkalinity of a water sample that has a pH of 9.5, 26.0 mg/L  $\text{CO}_3^{2-}$ , and 65.0 mg/L  $\text{HCO}_3^-$ .

**19.133** Human blood contains one buffer system based on phosphate species and one based on carbonate species. Assuming that blood has a normal pH of 7.4, what are the principal phosphate and carbonate species present? What is the ratio of the two phosphate species? (In the presence of the dissolved ions and other species in blood,  $K_{\text{a}1}$  of  $\text{H}_3\text{PO}_4 = 1.3 \times 10^{-2}$ ,  $K_{\text{a}2} = 2.3 \times 10^{-7}$ , and  $K_{\text{a}3} = 6 \times 10^{-12}$ ;  $K_{\text{a}1}$  of  $\text{H}_2\text{CO}_3 = 8 \times 10^{-7}$  and  $K_{\text{a}2} = 1.6 \times 10^{-10}$ .)

**19.134** Quantitative analysis of  $\text{Cl}^-$  ion is often performed by a titration with silver nitrate, using sodium chromate as an indicator. As standardized  $\text{AgNO}_3$  is added, both white  $\text{AgCl}$  and red

$\text{Ag}_2\text{CrO}_4$  precipitate, but as long as some  $\text{Cl}^-$  remains, the  $\text{Ag}_2\text{CrO}_4$  redissolves as the mixture is stirred. When the red color is permanent, the equivalence point has been reached.

(a) Calculate the equilibrium constant for the reaction

(b) Explain why the silver chromate redissolves.

(c) If 25.00 cm<sup>3</sup> of 0.1000 M NaCl is mixed with 25.00 cm<sup>3</sup> of 0.1000 M  $\text{AgNO}_3$ , what is the concentration of  $\text{Ag}^+$  remaining in solution? Is this sufficient to precipitate any silver chromate?

**19.135** An ecobotanist separates the components of a tropical bark extract by chromatography. She discovers a large proportion of quinidine, a dextrorotatory isomer of quinine used for control of arrhythmic heartbeat. Quinidine has two basic nitrogens ( $K_{\text{b}1} = 4.0 \times 10^{-6}$  and  $K_{\text{b}2} = 1.0 \times 10^{-10}$ ). To measure the concentration of quinidine, she carries out a titration. Because of the low solubility of quinidine, she first protonates both nitrogens with excess HCl and titrates the acidified solution with standardized base. A 33.85-mg sample of quinidine ( $\mathcal{M} = 324.41$  g/mol) is acidified with 6.55 mL of 0.150 M HCl.

(a) How many milliliters of 0.0133 M NaOH are needed to titrate the excess HCl?

(b) How many additional milliliters of titrant are needed to reach the first equivalence point of quinidine dihydrochloride?

(c) What is the pH at the first equivalence point?

**19.136** Some kidney stones form by the precipitation of calcium oxalate monohydrate ( $\text{CaC}_2\text{O}_4 \cdot \text{H}_2\text{O}$ ,  $K_{\text{sp}} = 2.3 \times 10^{-9}$ ). The pH of urine varies from 5.5 to 7.0, and the average  $[\text{Ca}^{2+}]$  in urine is  $2.6 \times 10^{-3}$  M.

(a) If the [oxalic acid] in urine is  $3.0 \times 10^{-13}$  M, will kidney stones form at pH = 5.5?

(b) Will they form at pH = 7.0?

(c) Vegetarians have a urine pH above 7. Are they more or less likely to form kidney stones?

**19.137** A biochemist needs a medium for acid-producing bacteria. The pH of the medium must not change by more than 0.05 pH units for every 0.0010 mol of  $\text{H}_3\text{O}^+$  generated by the organisms per liter of medium. A buffer consisting of 0.10 M HA and 0.10 M  $\text{A}^-$  is included in the medium to control its pH. What volume of this buffer must be included in 1.0 L of medium?

**19.138** A 35.00-mL solution of 0.2500 M HF is titrated with a standardized 0.1532 M solution of NaOH at 25°C.

(a) What is the pH of the HF solution before titrant is added?

(b) How many milliliters of titrant are required to reach the equivalence point?

(c) What is the pH at 0.50 mL before the equivalence point?

(d) What is the pH at the equivalence point?

(e) What is the pH at 0.50 mL after the equivalence point?

**19.139** Because of the toxicity of mercury compounds, mercury(I) chloride is used in antibacterial salves. The mercury(I) ion ( $\text{Hg}_2^{2+}$ ) consists of two bonded  $\text{Hg}^+$  ions.

(a) What is the empirical formula of mercury(I) chloride?

(b) Calculate  $[\text{Hg}_2^{2+}]$  in a saturated solution of mercury(I) chloride ( $K_{\text{sp}} = 1.5 \times 10^{-18}$ ).

(c) A seawater sample contains 0.20 lb of NaCl per gallon. Find  $[\text{Hg}_2^{2+}]$  if the seawater is saturated with mercury(I) chloride.

(d) How many grams of mercury(I) chloride are needed to saturate 4900 km<sup>3</sup> of pure water (the volume of Lake Michigan)?

(e) How many grams of mercury(I) chloride are needed to saturate 4900 km<sup>3</sup> of seawater?

**19.140** A 35.0-mL solution of 0.075 M CaCl<sub>2</sub> is mixed with 25.0 mL of 0.090 M BaCl<sub>2</sub>.

- If aqueous KF is added, which fluoride precipitates first?
- Describe how the metal ions can be separated using KF to form the fluorides.
- Calculate the fluoride ion concentration that will accomplish the separation.

**19.141** Rainwater is slightly acidic due to dissolved CO<sub>2</sub>. Use the following data to calculate the pH of unpolluted rainwater at 25°C: vol % in air of CO<sub>2</sub> = 0.040 vol %; solubility of CO<sub>2</sub> in pure water at 25°C and 1 atm = 88 mL CO<sub>2</sub>/100. mL H<sub>2</sub>O; K<sub>a1</sub> of H<sub>2</sub>CO<sub>3</sub> = 4.5 × 10<sup>-7</sup>.

**19.142** Seawater at the surface has a pH of about 8.5.

- Which of the following species has the highest concentration at this pH: H<sub>2</sub>CO<sub>3</sub>; HCO<sub>3</sub><sup>-</sup>; CO<sub>3</sub><sup>2-</sup>? Explain.
- What are the concentration ratios [CO<sub>3</sub><sup>2-</sup>]/[HCO<sub>3</sub><sup>-</sup>] and [HCO<sub>3</sub><sup>-</sup>]/[H<sub>2</sub>CO<sub>3</sub>] at this pH?
- In the deep sea, light levels are low, and the pH is around 7.5. Suggest a reason for the lower pH at the greater ocean depth. (*Hint*: Consider the presence or absence of plant and animal life and the effects on carbon dioxide concentrations.)

**19.143** Ethylenediaminetetraacetic acid (abbreviated H<sub>4</sub>EDTA) is a tetraprotic acid. Its salts are used to treat toxic metal poisoning by forming soluble complex ions that are then excreted. Because EDTA<sup>4-</sup> also binds essential calcium ions, it is often administered as the calcium disodium salt. For example, when Na<sub>2</sub>Ca(EDTA) is given to a patient, the [Ca(EDTA)]<sup>2-</sup> ions react with circulating Pb<sup>2+</sup> ions and the metal ions are exchanged:

A child has a dangerous blood lead level of 120 μg/100 mL. If the child is administered 100. mL of 0.10 M Na<sub>2</sub>Ca(EDTA), what is the final concentration of Pb<sup>2+</sup> in μg/100 mL blood, assuming that the exchange reaction and excretion process are 100% efficient? (Total blood volume is 1.5 L.)

**19.144** Buffers that are based on 3-morpholinopropanesulfonic acid (MOPS) are often used in RNA analysis. The useful pH range of a MOPS buffer is 6.5 to 7.9. Estimate the K<sub>a</sub> of MOPS.

**19.145** NaCl is purified by adding HCl to a saturated solution of NaCl (317 g/L). Will pure NaCl precipitate when 28.5 mL of 8.65 M HCl is added to 0.100 L of saturated solution?

**19.146** Scenes A to D represent tiny portions of 0.10 M aqueous solutions of a weak acid HA (red and blue; K<sub>a</sub> = 4.5 × 10<sup>-5</sup>), its conjugate base A<sup>-</sup>(red), or a mixture of the two (only these two species are shown):

- Which scene(s) show(s) a buffer?
- What is the pH of each solution?
- Arrange the scenes in sequence, assuming that they represent stages in a weak acid–strong base titration.
- Which scene represents the titration at its equivalence point?

**19.147** Scenes A to C represent aqueous solutions of the slightly soluble salt MZ (only the ions of this salt are shown):

- Which scene represents the solution just after solid MZ is stirred thoroughly in distilled water?
- If each sphere represents an ion concentration of 2.5 × 10<sup>-6</sup> M, what is the K<sub>sp</sub> of MZ?
- Which scene represents the solution after Na<sub>2</sub>Z(aq) has been added?
- If Z<sup>2-</sup> is CO<sub>3</sub><sup>2-</sup>, which scene represents the solution after the pH has been lowered?

**19.148** The solubility of Ag(I) in aqueous solutions containing different concentrations of Cl<sup>-</sup> is based on the following equilibria:

When solid AgCl is shaken with a solution containing Cl<sup>-</sup>, Ag(I) is present as both Ag<sup>+</sup> and AgCl<sub>2</sub><sup>-</sup>. The solubility of AgCl is the sum of the concentrations of Ag<sup>+</sup> and AgCl<sub>2</sub><sup>-</sup>.

- Show that [Ag<sup>+</sup>] in solution is given by

$$[\text{Ag}^+] = 1.8 \times 10^{-10} / [\text{Cl}^-]$$

and that [AgCl<sub>2</sub><sup>-</sup>] in solution is given by

$$[\text{AgCl}_2^-] = (3.2 \times 10^{-5}) ([\text{Cl}^-])$$

- Find the [Cl<sup>-</sup>] at which [Ag<sup>+</sup>] = [AgCl<sub>2</sub><sup>-</sup>].
- Explain the shape of a plot of AgCl solubility vs. [Cl<sup>-</sup>].
- Find the solubility of AgCl at the [Cl<sup>-</sup>] of part (b), which is the minimum solubility of AgCl in the presence of Cl<sup>-</sup>.

**19.149** EDTA binds metal ions to form complex ions (see Problem 19.143), so it is used to determine the concentrations of metal ions in solution:

A 50.0-mL sample of 0.048 M Co<sup>2+</sup> is titrated with 0.050 M EDTA<sup>4-</sup>. Find [Co<sup>2+</sup>] and [EDTA<sup>4-</sup>] after addition of (a) 25.0 mL and (b) 75.0 mL of EDTA<sup>4-</sup> (log K<sub>f</sub> of CoEDTA<sup>2-</sup> = 16.31).

## Concepts and Skills to Review Before You Study This Chapter

- › internal energy, heat, and work (Section 6.1)
- › state functions (Section 6.1) and standard states (Section 6.6)
- › enthalpy,  $\Delta H$ , and Hess's law (Sections 6.2 and 6.5)
- › entropy and solution formation (Section 13.3)
- › comparing  $Q$  and  $K$  to find reaction direction (Section 17.4)

In the last few chapters, we've examined some fundamental questions about change, whether chemical or physical: How fast does it occur? How far does it go toward completion? How is a change affected by concentration and temperature? And we've explored these questions in systems ranging from the stratosphere to a limestone cave to the cells of your body.

But why does the change occur in the first place? Some changes seem to happen *in one direction* but not the other. Copper statues turn green over time as the copper oxidizes (*photo*), but the green oxidation products do not react to re-form the shiny copper. Gasoline burns in air to produce carbon dioxide and water vapor as it runs a car engine, but those products do not react to form the gasoline and oxygen. A cube of sugar dissolves in a cup of coffee after a little stirring, but wait for another millennium and the dissolved sugar won't form the cube again. Chemists call these *spontaneous* changes. Most release energy, but some absorb it.

The principles of thermodynamics, developed almost 200 years ago, explain *why* a spontaneous change occurs. And, as far as we know, they apply to every change in every system in the universe—every working machine, every growing plant, every thinking student, every moving continent, every exploding star.

**IN THIS CHAPTER . . .** We discuss *why* changes occur and how we can utilize them by focusing on the concepts of entropy and free energy and their relation to the direction of a spontaneous change.

- › We discuss the need for a criterion to predict the *direction* of a spontaneous change.
- › We review the first law of thermodynamics and see that it accounts for the energy of a change but *not* the direction.
- › We see that the sign of the enthalpy change does not predict the direction either.
- › We find the criterion for predicting the direction of a spontaneous change in the second law of thermodynamics, which focuses on entropy ( $S$ ), a state function based on the natural tendency of a system's energy to become dispersed.
- › We examine entropy changes for exothermic and endothermic processes.
- › We develop the concept of free energy as a simplified criterion for the occurrence of spontaneous change and see how free energy relates to the work a system can do.
- › We explore the key relationship between the free energy change of a reaction and its equilibrium constant.

### 20.1 THE SECOND LAW OF THERMODYNAMICS: PREDICTING SPONTANEOUS CHANGE

A **spontaneous change** of a system is one that occurs under specified conditions without a continuous input of energy from outside the system. The freezing of water, for example, is spontaneous at 1 atm and  $-5^{\circ}\text{C}$ . A spontaneous process, such as burning or falling, may need a little “push” to get started—a spark to ignite gasoline vapors in your car's engine, a shove to knock a book off your desk—but once the process begins, it supplies the energy needed for it to continue. In contrast, a *nonspontaneous* change occurs only if the surroundings *continuously* supply the system with an input of energy. Under given conditions, *if a change is spontaneous in one direction, it is not spontaneous in the other*. A book falls off your desk spontaneously, but does not spontaneously move from floor to desk.

The term *spontaneous* does not mean “instantaneous” nor does it reveal anything about how long a process takes to occur; it means that, given enough time, the process will happen by itself. Many processes are spontaneous but slow—including ripening, rusting, and aging.

Can we predict the direction of a spontaneous change in cases that are not as obvious as burning gasoline or falling books? In this section, we first briefly consider two concepts that do *not* predict the direction of a spontaneous change and then focus on one that does—the concept of entropy. In Section 20.1, we examine several aspects of this central idea. We discuss the meaning of entropy in terms of the relation between the freedom of motion of the particles in a system and the dispersal of its kinetic energy. Then, we show how to obtain the change in a system’s entropy through a statistical approach and through the measurement of changes in heat or work. We explore entropy changes during a phase change and during a change in temperature. Finally, you’ll see how to compare the relative entropy of systems based on temperature, physical state, whether pure or dissolved, and the atomic or molecular structure.

## The First Law of Thermodynamics Does Not Predict Spontaneous Change

Let’s see whether energy changes can predict the direction of spontaneous change. Recall from Chapter 6 that the first law of thermodynamics (law of energy conservation) states that the internal energy ( $E$ ) of a system, the sum of the kinetic and potential energies of its particles, changes when heat ( $q$ ) and/or work ( $w$ ) are absorbed or released:

$$\Delta E = q + w$$

Whatever is not part of the system (sys) is part of the surroundings (surr); thus, *the change in energy and, therefore, the heat and/or work absorbed by the system are released by the surroundings*, or vice versa:

$$\Delta E_{\text{sys}} = -\Delta E_{\text{surr}} \quad \text{or} \quad (q + w)_{\text{sys}} = -(q + w)_{\text{surr}}$$

Since the system plus the surroundings is the universe (univ), it follows that *the total energy of the universe is constant, so the change in energy of the universe is zero*:\*

$$\Delta E_{\text{sys}} + \Delta E_{\text{surr}} = -\Delta E_{\text{surr}} + \Delta E_{\text{surr}} = 0 = \Delta E_{\text{univ}}$$

The first law accounts for the energy, but not the direction, of a process. When gasoline burns in a car engine, the first law states that the potential energy difference between the bonds in the fuel mixture and those in the exhaust gases is converted to the kinetic energy of the moving car and its parts plus the heat released to the environment. But, why doesn’t the heat released in the engine convert exhaust fumes back into gasoline and oxygen? When an ice cube melts in your hand, the first law states that energy from your hand is converted to kinetic energy as the solid changes to a liquid. But, why doesn’t the pool of water in your cupped hand transfer the heat back to your hand and refreeze? Neither of these events violates the first law—if you measure the work and heat in each case, you find that energy is conserved—but these reverse changes never happen. That is, *the first law by itself does not predict the direction of a spontaneous change*.

## The Sign of $\Delta H$ Does Not Predict Spontaneous Change

Perhaps the sign of the enthalpy change ( $\Delta H$ ), the heat gained or lost at constant pressure ( $q_p$ ), is the criterion for spontaneity; in fact, leading scientists thought so through most of the 19<sup>th</sup> century. If so, we would expect exothermic processes ( $\Delta H < 0$ ) to be spontaneous and endothermic processes ( $\Delta H > 0$ ) to be nonspontaneous. Let’s examine some examples to see if this is true.

1. *Spontaneous processes with  $\Delta H < 0$ .* All freezing and condensing processes are exothermic and spontaneous at certain conditions:

\*Any modern statement of conservation of energy must take into account mass-energy equivalence and the processes in stars, which convert enormous amounts of matter into energy. Thus, the total *mass-energy* of the universe is constant.

The burning of methane and all other combustion reactions are spontaneous and exothermic:

Oxidation of iron and other metals occurs spontaneously and exothermically:

Ionic compounds form spontaneously and exothermically from their elements:

2. *Spontaneous processes with  $\Delta H > 0$ .* In many cases, an exothermic process occurs spontaneously under one set of conditions, whereas the opposite, endothermic, process occurs spontaneously under another set. All melting and vaporizing processes are endothermic *and* spontaneous at certain conditions:

At ordinary pressure, water vaporizes spontaneously:

Most soluble salts dissolve endothermically *and* spontaneously:

Even some endothermic reactions are spontaneous:

In the latter reaction, ionic solids are mixed (Figure 20.1A) and the waters of hydration released by the  $\text{Ba}(\text{OH})_2$  solvate the ions. The reaction mixture absorbs heat from the surroundings so quickly that the beaker freezes to a wet board (Figure 20.1B).

Considering just these few examples, we see that, as for the first law, *the sign of  $\Delta H$  by itself does not predict the direction of a spontaneous change.*

## Freedom of Particle Motion and Dispersal of Kinetic Energy

When we look closely at the previous examples of spontaneous *endothermic* processes, they have one major feature in common: in every case, the chemical entities—atoms, molecules, or ions—have more freedom of motion *after* the change. Put another way, after the change, the particles have a wider range of energy of motion (kinetic energy); we say that their energy has become more dispersed, distributed, or spread out:

- The phase changes convert a solid, in which motion is restricted, to a liquid, in which particles have more freedom to move around each other, and then to a gas, in which the particles have much greater freedom of motion. Thus, the energy of motion is more dispersed.
- Dissolving a salt changes a crystalline solid and a pure liquid into separate ions and solvent molecules moving and interacting, so their freedom of motion is greater and their energy of motion more dispersed.
- In the chemical reactions, *fewer* moles of crystalline solids produce *more* moles of gases and/or solvated ions, so once again, the freedom of motion of the particles increases and their energy of motion is more dispersed:

**Figure 20.1** A spontaneous endothermic reaction.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

*In thermodynamic terms, a change in the freedom of motion of particles in a system, that is, in the dispersal of their energy of motion, is a key factor for predicting the direction of a spontaneous process.*

## Entropy and the Number of Microstates

Earlier, we discussed the quantized *electronic* energy levels of an atom (Chapter 7) and a molecule (Chapter 11), and mentioned the quantized *kinetic* energy levels—vibrational, rotational, and translational—of a molecule (see Chapter 9, Tools of the Laboratory). Now, we'll see that the energy state of a whole system of atoms or molecules is quantized, too.

**Energy Dispersal and the Meaning of Entropy** Let's see why freedom of motion and dispersal of energy relate to spontaneous change:

- *Quantization of energy.* Picture a system of, say, 1 mol of N<sub>2</sub> gas and focus on one molecule. At any instant, it is moving through space (translating) at some speed and rotating at some frequency, and its atoms are vibrating at some frequency. In the next instant, the molecule collides with another or with the container, and these motional (kinetic) energy states change to different values. The complete quantum state of the molecule at any instant consists of its electronic states and these translational, rotational, and vibrational states. In this discussion, we focus on the latter three, that is, on the kinetic energy states.
- *Number of microstates.* The energy of all the molecules in a system is similarly quantized. Each quantized state of the system is called a **microstate**, and at any instant, the total energy of the system is dispersed throughout one microstate. In the next instant, it is dispersed throughout a different microstate. The number of microstates possible for a system of 1 mol of molecules is staggering, on the order of 10<sup>10<sup>23</sup></sup>.
- *Dispersal of energy.* At a given set of conditions, each microstate has the *same* total energy as any other. Therefore, each microstate is equally possible for the system, and the laws of probability say that, over time, all microstates are equally likely. The number of microstates for a system is the number of ways it can disperse (distribute or spread) its kinetic energy among the various motions of all its particles.

In 1877, the Austrian mathematician and physicist Ludwig Boltzmann related the number of microstates ( $W$ ) to the **entropy** ( $S$ ) of a system:

$$S = k \ln W \quad (20.1)$$

where  $k$ , the *Boltzmann constant*, is the universal gas constant ( $R$ , 8.314 J/mol·K) divided by Avogadro's number ( $N_A$ ), that is,  $R/N_A$ , which equals  $1.38 \times 10^{-23}$  J/K. The term  $W$  is the number of microstates, so it has no units; therefore,  $S$  has units of joules/kelvin (J/K). Thus,

- A system with fewer microstates (smaller  $W$ ) has *lower entropy* (lower  $S$ ).
- A system with more microstates (larger  $W$ ) has *higher entropy* (higher  $S$ ).

For our earlier examples of endothermic processes,

lower entropy (fewer microstates) → higher entropy (more microstates)

Phase change: solid → liquid → gas

Dissolving of salt: crystalline solid + liquid → ions in solution

Chemical change: crystalline solids → gases + ions in solution

(Recall from Chapter 13 that entropy is a key factor in the formation of solutions.)

**Entropy as a State Function** If a change results in a greater number of microstates, there are more ways to disperse the energy of the system and the entropy increases:

$$S_{\text{more microstates}} > S_{\text{fewer microstates}}$$

If a change results in a lower number of microstates, the entropy decreases. Like internal energy ( $E$ ) and enthalpy ( $H$ ), *entropy is a state function*, so it depends only on the present state of the system, not on how it arrived at that state (see Chapter 6).

Therefore, the change in entropy of the system ( $\Delta S_{\text{sys}}$ ) depends only on the *difference* between its final and initial values:

$$\Delta S_{\text{sys}} = S_{\text{final}} - S_{\text{initial}}$$

As with any state function,  $\Delta S_{\text{sys}} > 0$  when the value of  $S$  increases during a change. For example, for the phase change when dry ice sublimates, the entropy increases since gaseous  $\text{CO}_2$  has more microstates and higher entropy than solid  $\text{CO}_2$ :

And,  $\Delta S_{\text{sys}} < 0$  when the entropy decreases; when water vapor condenses, for example, the entropy decreases since liquid  $\text{H}_2\text{O}$  has fewer microstates and lower entropy than gaseous  $\text{H}_2\text{O}$ :

As an example of a reaction during which entropy increases, consider the decomposition of dinitrogen tetroxide ( $\text{N}_2\text{O}_4$ , written here as  $\text{O}_2\text{N}-\text{NO}_2$ ):

When the N—N bond in 1 mol of dinitrogen tetroxide breaks, the 2 mol of  $\text{NO}_2$  molecules have many more possible motions; thus, at any instant, the energy of the system is dispersed into any one of a larger number of microstates. Thus, the change in entropy of the system, which is the change in entropy of the reaction ( $\Delta S_{\text{rxn}}$ ), goes up:

$$\Delta S_{\text{sys}} = \Delta S_{\text{rxn}} = S_{\text{final}} - S_{\text{initial}} = S_{\text{products}} - S_{\text{reactants}} = 2S_{\text{NO}_2} - S_{\text{O}_2\text{N}-\text{NO}_2} > 0$$

**Quantitative Meaning of an Entropy Change—Counting Microstates** We consider two approaches for quantifying a change in entropy. The first is a statistical approach, which we discuss here; the second relies on the measurement of thermodynamic variables, and we discuss it later. The statistical approach is based on *counting the number of microstates* possible for a system. We will consider a system of 1 mole of a gas expanding from 1 L to 2 L and behaving ideally, much as neon does at 298 K:

Figure 20.2 shows two flasks connected by a stopcock—the right flask is evacuated, and the left flask contains 1 mol of neon. When we open the stopcock, the gas expands until each flask contains 0.5 mol—but *why*? Opening the stopcock increases the volume, which increases the number of translational energy levels the particles can occupy as they move to more locations. Thus, the number of microstates—and the entropy—increases.

**Figure 20.2** Spontaneous expansion of a gas. **A**, With the stopcock closed, the left flask contains 1 mol of Ne. **B**, With the stopcock open, the gas expands and each flask contains 0.5 mol of Ne.

Figure 20.3 presents this idea with particles on energy levels in a box of changeable volume. When the stopcock opens, there are more energy levels, and they are closer together on average, so more distributions of particles are possible.

In Figure 20.4 (*next page*), the number of microstates is represented by the placement of particles in the left and/or right flasks:

- *One Ne atom.* At a given instant, a Ne atom in the left flask has its energy in one of some number ( $W$ ) of microstates. Opening the stopcock increases the volume, which increases the number of possible locations and the number of translational energy levels. Thus, the system has  $2^1$ , or 2, times as many microstates available when the atom moves through both flasks (final state,  $W_{\text{final}}$ ) as when it is confined to the left flask (initial state,  $W_{\text{initial}}$ ).
- *Two Ne atoms.* For atoms A and B moving through both flasks, there are  $2^2$ , or 4, times as many microstates as when the atoms were initially in the left flask—some number of microstates with both A and B in the left, that many with A in the left and B in the right or with B in the left and A in the right, and that many with both in the right.

**Figure 20.3** The entropy increase due to expansion of a gas. Energy levels are shown as lines in a box of narrow width (*left*). Each distribution of energies for the 21 particles is one microstate. When the stopcock is opened, the box is wider (volume increases, *right*), and the particles have more energy levels available.

**Figure 20.4** Expansion of a gas and the increase in number of microstates. Each set of particle locations represents a different microstate. When the volume increases (stopcock opens), the *relative* number of microstates is  $2^n$ , where  $n$  is the number of particles.

- *Three Ne atoms.* Add another atom, and there are  $2^3$ , or 8, times as many microstates when the stopcock is open.
- *Ten Ne atoms.* With 10 Ne atoms, there are  $2^{10}$ , or 1024, times as many microstates for the atoms in both flasks as there were for the 10 atoms in the left flask.
- *One mole of Ne atoms.* With 1 mol ( $N_A$ ) of Ne, there are  $2^{N_A}$  times as many microstates for the atoms in the larger volume ( $W_{\text{final}}$ ) than in the smaller ( $W_{\text{initial}}$ ):

$$\frac{W_{\text{final}}}{W_{\text{initial}}} = 2^{N_A}$$

Now let's find  $\Delta S_{\text{sys}}$  through the Boltzmann equation,  $S = k \ln W$ . From the properties of logarithms (Appendix A), we know that  $\ln A - \ln B = \ln A/B$ . Thus,

$$\Delta S_{\text{sys}} = S_{\text{final}} - S_{\text{initial}} = k \ln W_{\text{final}} - k \ln W_{\text{initial}} = k \ln \frac{W_{\text{final}}}{W_{\text{initial}}} = k \ln 2^{6.02 \times 10^{23}}$$

Also, from Appendix A,  $\ln A^y = y \ln A$ ; so we have

$$\begin{aligned} \Delta S_{\text{sys}} &= k \ln 2^{6.02 \times 10^{23}} = k(6.02 \times 10^{23})(\ln 2) \\ &= (1.38 \times 10^{-23} \text{ J/K})(6.02 \times 10^{23})(0.693) = 5.76 \text{ J/K} \end{aligned}$$

## Quantitative Meaning of an Entropy Change—Measuring Thermodynamic Variables

The second approach to quantifying an entropy change measures thermodynamic quantities such as heat and enthalpy that occur during the expansion (or contraction) of gases, phase changes, and the heating of a system.

**Entropy Change During an Isothermal Process** The great German physicist Rudolf Clausius (1822–1888) defined the entropy change from an initial state to a final state for a reversible process in terms of the heat transfer involved,  $dq$ , divided by the temperature,  $T$ :

$$\Delta S = S_{\text{final}} - S_{\text{initial}} = \int_{\text{initial}}^{\text{final}} \frac{dq_{\text{rev}}}{T}$$

A **reversible process** is one that occurs in such tiny increments that the system remains at equilibrium and the direction of the change can be reversed by an *infinitesimal* reversal of conditions. If the process takes place at constant temperature, it is called an **isothermal process**, and the equation for  $\Delta S$  can be integrated to obtain

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} \quad (20.2)$$

We'll approximate a reversible, isothermal expansion by placing 1 mol of Ne gas in a piston-cylinder assembly within a heat reservoir to maintain a constant  $T$  of 298 K and start by confining the gas to a volume of 1 L by the “pressure” of a beaker of sand on the piston (Figure 20.5). We remove one grain of sand (an “infinitesimal” decrease in pressure) with a pair of tweezers, and the gas (system) expands a tiny amount, raising the piston and doing work,  $-w$ . Assuming Ne behaves ideally, it absorbs an equivalent tiny increment of heat,  $q$ , from the heat reservoir. With each grain of sand removed, the expanding gas absorbs another tiny increment of heat. This process simulates a reversible expansion because we can reverse it by putting back a grain of sand, which causes the surroundings to do a tiny quantity of work compressing the gas, thus releasing a tiny quantity of heat to the reservoir.

If we continue this nearly reversible expansion to 2 L and use calculus to integrate the tiny increments of heat together,  $q_{\text{rev}}$  is 1718 J. From Equation 20.2,

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} = \frac{1718 \text{ J}}{298 \text{ K}} = 5.76 \text{ J/K}$$

Another way to calculate the entropy change for this reversible, isothermal process is to consider the tiny increments of work done by the gas during expansion:

$$dw = -PdV$$

For an ideal gas,  $P = \frac{nRT}{V}$ , which replaces  $P$  in the work equation to give

$$dw = -\frac{nRT}{V}dV$$

Integrating this relationship from the initial to the final volume gives

$$w = -nRT \int_{V_{\text{initial}}}^{V_{\text{final}}} \frac{dV}{V} = -nRT \ln \frac{V_{\text{final}}}{V_{\text{initial}}}$$

For an isothermal process involving an ideal gas,  $\Delta E = q + w = 0$  and therefore  $q = -w$ ; thus, the equation above can be written as

$$q_{\text{rev}} = nRT \ln \frac{V_{\text{final}}}{V_{\text{initial}}}$$

When this relationship is combined with Equation 20.2, we obtain

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} = \frac{nRT \ln(V_{\text{final}}/V_{\text{initial}})}{T}$$

or

$$\Delta S_{\text{sys}} = nR \ln \frac{V_{\text{final}}}{V_{\text{initial}}} \quad (20.3)$$

For the reversible expansion of 1 mol of neon from 1 L to 2 L shown in Figure 20.5, we have

$$\Delta S_{\text{sys}} = nR \ln \frac{V_{\text{final}}}{V_{\text{initial}}} = (1 \text{ mol})(8.314 \text{ J/mol}\cdot\text{K}) \ln \frac{2.0 \text{ L}}{1.0 \text{ L}} = 5.76 \text{ J/K}$$

Note that this value of  $\Delta S_{\text{sys}}$ , obtained from integrating increments of work, is the same as the value we obtained from integrating increments of heat (Equation 20.2) and is also the same as the value we obtained from counting the number of microstates. We would obtain the entropy change accompanying a reversible, isothermal *contraction* of an ideal gas in the same way, but  $V_{\text{final}}$  would be *smaller* than  $V_{\text{initial}}$ .

Figure 20.5 Simulating a reversible process.

Recall that Boyle's law (Equation 5.1) shows the inverse relationship between the volume and pressure of a fixed amount of ideal gas at constant temperature:

$$P_{\text{initial}}V_{\text{initial}} = P_{\text{final}}V_{\text{final}} \quad \text{or} \quad \frac{V_{\text{final}}}{V_{\text{initial}}} = \frac{P_{\text{initial}}}{P_{\text{final}}}$$

Substituting the relationship from Boyle's law into Equation 20.3 expresses the entropy change for an isothermal expansion or contraction of an ideal gas in terms of pressure:

$$\Delta S_{\text{sys}} = nR \ln \frac{P_{\text{initial}}}{P_{\text{final}}} \quad (20.4)$$

### SAMPLE PROBLEM 20.1

### Calculating the Change in Entropy During an Isothermal Volume Change of an Ideal Gas

**Problem** What is the change in entropy of 75.0 g of neon gas when it undergoes isothermal contraction from 16.2 L to 12.1 L? Assume ideal gas behavior.

**Plan** We know the mass (75.0 g) and the initial (16.2 L) and final (12.1 L) volumes of the gas and we have to find  $\Delta S$  of the contraction. To do so, we use Equation 20.3 after converting the mass (g) to amount (mol).

**Solution** Converting from mass (g) to amount (mol):

$$\text{Amount (mol) of Ne} = 75.0 \text{ g Ne} \times \frac{1 \text{ mol Ne}}{20.18 \text{ g Ne}} = 3.72 \text{ mol Ne}$$

Calculating  $\Delta S$ :

$$\Delta S_{\text{sys}} = nR \ln \frac{V_{\text{final}}}{V_{\text{initial}}} = 3.72 \text{ mol} \times 8.314 \text{ J/mol}\cdot\text{K} \times \ln \frac{12.1 \text{ L}}{16.2 \text{ L}} = -9.02 \text{ J/K}$$

**Check** Since the gaseous atoms are now in a smaller volume, fewer microstates are possible and thus the entropy should decrease. The calculated entropy change is negative, as expected for a decrease in entropy. Rounding gives  $4.0 \text{ mol} \times 8 \text{ J/mol}\cdot\text{K} \times \ln 0.75 = -9 \text{ J/K}$ .

### FOLLOW-UP PROBLEMS

*Brief Solutions for all Follow-up Problems appear at the end of the chapter.*

**20.1A** Calculate the entropy change for 200.0 g of  $\text{N}_2$  gas that is compressed from a pressure of 0.715 atm to a pressure of 1.16 atm at a constant temperature of  $30.0^\circ\text{C}$ . Assume that the gas behaves ideally.

**20.1B** Calculate the entropy change that occurs when 100. g of  $\text{CO}_2$  gas expands from 3.35 L to 4.75 L at a constant temperature of 298 K. Assume ideal gas behavior.

**SOME SIMILAR PROBLEMS** 20.112 and 20.113

**Entropy Change During a Phase Change** Equation 20.2 can also be used to calculate the change in entropy for a phase change such as melting (fusion) or vaporization, since these are isothermal processes:

$$\Delta S_{\text{fus}} = \frac{\Delta H_{\text{fus}}}{T_f} \quad \text{and} \quad \Delta S_{\text{vap}} = \frac{\Delta H_{\text{vap}}}{T_b} \quad (20.5)$$

where  $\Delta H_{\text{fus}}$  is the enthalpy of fusion,  $\Delta H_{\text{vap}}$  is the enthalpy of vaporization, and  $T_f$  and  $T_b$  are the melting point and boiling point, respectively. Note that we can replace  $q_{\text{rev}}$  in Equation 20.2 by  $\Delta H$  in Equation 20.5 because the phase transition occurs at constant pressure (see Equation 6.6).

A very interesting observation made in the late 19<sup>th</sup> century, known as **Trouton's rule**, shows that most liquids have a  $\Delta S_{\text{vap}}$  value close to  $88 \text{ J/mol}\cdot\text{K}$  (Table 20.1, *next page*). This finding implies that the entropies of most substances in the liquid phase

Table 20.1

Boiling Point ( $T_b$ ), Molar Enthalpy of Vaporization, ( $H_{\text{vap}}$ ), and Molar Entropy of Vaporization ( $S_{\text{vap}}$ ) of Several Substances

Substance	$T_b$ (K)	$H_{\text{vap}}$ (kJ/mol)	$S_{\text{vap}}$ (J/mol·K)
Acetone (CH <sub>3</sub> COCH <sub>3</sub> )	329.4	29.1	88.3
Benzene (C <sub>6</sub> H <sub>6</sub> )	353.2	31.0	87.7
Carbon tetrachloride (CCl <sub>4</sub> )	349.8	32.5	92.9
Diethyl ether (C <sub>2</sub> H <sub>5</sub> ) <sub>2</sub> O	308.6	27.4	88.8
Ethanol C <sub>2</sub> H <sub>5</sub> OH	351.4	39.3	111.8
Mercury (Hg)	630	59.0	93.7
Methane (CH <sub>4</sub> )	109	9.2	84
Methanol (CH <sub>3</sub> OH)	337.8	35.5	105
Water (H <sub>2</sub> O)	373.15	40.79	109.4

have a similar number of microstates, as do the substances in the gas phase; thus, the entropy difference between the two phases gives a consistent value. The greatest deviations in Table 20.1 from the  $\Delta S_{\text{vap}}$  value of Trouton's rule occur for water, ethanol (C<sub>2</sub>H<sub>5</sub>OH), and methanol (CH<sub>3</sub>OH), all of which are higher than expected. A common structural feature of these compounds is their ability to form H bonds, and we attribute the deviations to the fact that hydrogen bonding in the liquid phase restricts freedom of molecular motion, so these three liquids would have a lower number of microstates and lower than expected entropies. In the gas phase, however, these three substances have a similar number of microstates as other substances since the molecules are too far apart for hydrogen bonding to affect freedom of motion. Thus, the liquids that can form H bonds have a greater increase in entropy upon vaporizing than liquids that cannot.

Sample Problem 20.2 shows how we find the change in entropy,  $\Delta S$ , that accompanies a phase change.

## SAMPLE PROBLEM 20.2

## Calculating the Change in Entropy During a Phase Change

**Problem** Calculate the change in entropy in J/K for

- (a) the vaporization of 10.0 g of water at 100.°C ( $\Delta H_{\text{vap}} = 40.7$  kJ/mol).  
 (b) the melting of 10.0 g of ice at 0.0°C ( $\Delta H_{\text{fus}} = 6.02$  kJ/mol).

**Plan** We'll combine the Plans for parts (a) and (b) because the steps are similar. We know the mass (10.0 g), the boiling point (100.°C), the melting point (0.0°C), and the values of  $\Delta H_{\text{vap}}$  and  $\Delta H_{\text{fus}}$ , and we have to find  $\Delta S$  of the phase changes. To do so, we use Equation 20.5, so we find the total  $\Delta H$  for the amount of substance and divide by the boiling or melting point. We convert the temperatures from °C to K and the mass (g) to amount (mol). Then we multiply the amount by  $\Delta H_{\text{vap}}$  and  $\Delta H_{\text{fus}}$  to find  $\Delta H$  (in J). Finally, we apply Equation 20.5.

**Solution** Converting  $T$  from °C to K:

$$T_b (\text{K}) = 100.^\circ\text{C} + 273.15 = 373 \text{ K} \quad T_f (\text{K}) = 0.0^\circ\text{C} + 273.15 = 273.15 = 273.2 \text{ K}$$

Converting from mass (g) to amount (mol):

$$\text{Amount (mol) of H}_2\text{O} = 10.0 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.0 \text{ g H}_2\text{O}} = 0.556 \text{ mol H}_2\text{O}$$

Finding  $\Delta H$  from the molar enthalpies and the amount (mol):

(a) For vaporization:

$$\Delta H(\text{J}) = 0.556 \text{ mol H}_2\text{O} \times \frac{40.7 \text{ kJ}}{1 \text{ mol H}_2\text{O}} \times \frac{10^3 \text{ J}}{1 \text{ kJ}} = 22,629 \text{ J}$$

(b) For melting:

$$\Delta H(\text{J}) = 0.556 \text{ mol H}_2\text{O} \times \frac{6.02 \text{ kJ}}{1 \text{ mol H}_2\text{O}} \times \frac{10^3 \text{ J}}{1 \text{ kJ}} = 3,347 \text{ J}$$

Calculating  $\Delta S$ :

$$\text{(a)} \quad \Delta S_{\text{vap}} = \frac{\Delta H_{\text{vap}}}{T_{\text{b}}} = \frac{22,629 \text{ J}}{373 \text{ K}} = 60.7 \text{ J/K}$$

$$\text{(b)} \quad \Delta S_{\text{fus}} = \frac{\Delta H_{\text{fus}}}{T_{\text{f}}} = \frac{3,347 \text{ J}}{273.2 \text{ K}} = 12.25 \text{ J/K}$$

**Check** The units are correct. Since  $\Delta H_{\text{fus}} < \Delta H_{\text{vap}}$ ,  $\Delta S_{\text{fus}} < \Delta S_{\text{vap}}$ . The arithmetic seems correct: in (a), for example, rounding gives  $23,000 \text{ J}/400 \text{ K} = 57.5 \text{ J/K}$ .

#### FOLLOW-UP PROBLEMS

**20.2A** Calculate the entropy change for the vaporization of 34.0 g of acetone,  $\text{C}_3\text{H}_6\text{O}$ , at its boiling point of  $56.2^\circ\text{C}$ . The heat of vaporization for acetone is  $31.3 \text{ kJ/mol}$ .

**20.2B** Calculate the entropy change for the freezing of 112 g of ethanol,  $\text{C}_2\text{H}_5\text{OH}$ , at its freezing point of  $-114^\circ\text{C}$ . The heat of fusion for ethanol is  $5.02 \text{ kJ/mol}$ .

**SOME SIMILAR PROBLEMS** 20.114 and 20.115

**Entropy Change Due to a Temperature Change** We can calculate the change in entropy due to a change in temperature by integrating Equation 20.2 from  $T_1$  to  $T_2$ :

$$\Delta S_{\text{sys}} = \int_{T_1}^{T_2} \frac{dq_{\text{rev}}}{T}$$

We saw in Section 6.3 that the quantity of heat absorbed or released by  $n$  moles of substance during a temperature change is determined by the molar heat capacity,  $C_{\text{m}}$ :

$$q = n \times C_{\text{m}} \times \Delta T \quad \text{or} \quad dq = n \times C_{\text{m}} \times dT$$

Combining these two equations gives

$$\Delta S_{\text{sys}} = \int_{T_1}^{T_2} \frac{nC_{\text{m}}}{T} dT$$

We remove  $n$  from the quantity to be integrated and we'll assume that  $C_{\text{m}}$  is independent of temperature, so it can be removed, too, and we have

$$\Delta S_{\text{sys}} = nC_{\text{m}} \int_{T_1}^{T_2} \frac{1}{T} dT$$

If the temperature change occurs at constant volume, we use the *constant-volume molar heat capacity*,  $C_{\text{V,m}}$ , and integrate to obtain

$$\Delta S_{\text{sys}} = nC_{\text{V,m}} \ln \frac{T_2}{T_1} \quad (20.6)$$

The *constant-pressure molar heat capacity*,  $C_{\text{P,m}}$ , is used for temperature changes occurring at constant pressure:

$$\Delta S_{\text{sys}} = nC_{\text{P,m}} \ln \frac{T_2}{T_1} \quad (20.7)$$

We use these quantities to find the change in entropy when the temperature changes.

#### SAMPLE PROBLEM 20.3

#### Calculating the Entropy Change Resulting from a Change in Temperature

**Problem** Calculate the entropy change when a 700.-g sample of mercury is heated from  $25^\circ\text{C}$  to  $250.^\circ\text{C}$  at constant pressure.  $C_{\text{P,m}}$  for mercury =  $27.98 \text{ J/mol}\cdot\text{K}$ .

**Plan** We know the mass (700. g), the initial ( $25.0^\circ\text{C}$ ) and final ( $250.^\circ\text{C}$ ) temperatures, and the constant-pressure molar heat capacity ( $27.98 \text{ J/mol}\cdot\text{K}$ ), and we need to find  $\Delta S$ . We convert the mass (g) to amount (mol) and the temperatures from  $^\circ\text{C}$  to K. We then use Equation 20.7 to calculate the entropy change.

**Solution** Converting from mass (g) to amount (mol):

$$\text{Amount (mol) of Hg} = 700. \text{ g} \times \frac{1 \text{ mol Hg}}{200.6 \text{ g Hg}} = 3.49 \text{ mol Hg}$$

Converting  $T$  from  $^{\circ}\text{C}$  to K:

$$T_1 (\text{K}) = 25^{\circ}\text{C} + 273.15 = 298 \text{ K} \quad T_2 (\text{K}) = 250.0^{\circ}\text{C} + 273.15 = 523 \text{ K}$$

Calculating  $\Delta S$ :

$$\Delta S_{\text{sys}} = nC_{p,m} \ln \frac{T_2}{T_1} = 3.49 \text{ mol} \times 27.98 \text{ J/mol}\cdot\text{K} \times \ln \frac{523 \text{ K}}{298 \text{ K}} = 54.9 \text{ J/K}$$

**Check** The units are correct. Rounding gives  $3.5 \text{ mol} \times 28 \text{ J/mol}\cdot\text{K} \times \ln 1.7 = 50 \text{ J/K}$ .

### FOLLOW-UP PROBLEMS

**20.3A** Calculate the entropy change when a 375-g sample of nitrogen gas is cooled from  $25^{\circ}\text{C}$  to  $0^{\circ}\text{C}$  at constant volume.  $C_{v,m}$  for nitrogen =  $20.8 \text{ J/mol}\cdot\text{K}$ .

**20.3B** When 100. g of water at  $25^{\circ}\text{C}$  is heated at constant pressure,  $\Delta S$  is  $70.9 \text{ J/K}$ . What is the final temperature of the water (in  $^{\circ}\text{C}$ )?  $C_{p,m}$  for water =  $75.3 \text{ J/mol}\cdot\text{K}$ .

**SOME SIMILAR PROBLEMS** 20.116 and 20.117

## Entropy and the Second Law of Thermodynamics

The change in entropy determines the direction of a spontaneous process, but we must consider more than just the entropy change of the *system*. After all, at  $20^{\circ}\text{C}$ , solid water melts spontaneously and  $\Delta S_{\text{sys}}$  goes up, while at  $-10^{\circ}\text{C}$ , liquid water freezes spontaneously and  $\Delta S_{\text{sys}}$  goes down. But when we consider *both* the system *and* its surroundings, we find the following:

- *All real processes occur spontaneously in the direction that increases the entropy of the universe (system plus surroundings).* This is one way to state the **second law of thermodynamics**.

The second law says that *either* the entropy change of the system *or* that of the surroundings may be negative. But, for a process to be spontaneous, the *sum* of the two entropy changes must be positive. If the entropy of the system decreases, the entropy of the surroundings must increase even more to offset that decrease, so that the entropy of the universe (system *plus* surroundings) increases. A quantitative statement of the second law, for any real spontaneous process, is

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} > 0 \quad (20.8)$$

(We return to this idea in Section 20.2.)

## Standard Molar Entropies and the Third Law

Entropy and enthalpy are state functions, but their values differ in a fundamental way:

- For *enthalpy*, there is no zero point, so we can measure only *changes*.
- For *entropy*, there *is* a zero point, and we can determine *absolute* values by applying the **third law of thermodynamics**: *a perfect crystal has zero entropy at absolute zero*:  $S_{\text{sys}} = 0$  at  $0 \text{ K}$ .

A “perfect” crystal means all the particles are aligned flawlessly. At absolute zero, the particles have minimum energy, so there is only one microstate. Thus, in Equation 20.1,

$$W = 1 \quad \text{so} \quad S = k \ln 1 = 0$$

When we warm the crystal to any temperature above  $0 \text{ K}$ , the total energy increases, so it can be dispersed into more than one microstate. Thus,

$$W > 1 \quad \text{and} \quad \ln W > 0 \quad \text{so} \quad S > 0$$

To find  $S$  of 1 mole of substance at a given temperature,  $T$ , we use the equation for the change in entropy due to a change in temperature at constant pressure and the fact that  $S = 0$  at 0 K:

$$\Delta S_{\text{sys}} = S(T) - S(0 \text{ K}) = C_p \int_0^T \frac{1}{T} dT$$

The heat capacity  $C_p$  is measured at all temperatures from  $T = 0$  K to the temperature of interest, usually 298 K. From a graph of  $C_p/T$  vs  $T$ , the area under the curve is the entropy of the substance at  $T$ . If the substance undergoes a phase change during the heating process from 0 K to  $T$ , the entropy change for the phase change must be added to the  $S$  value obtained from the graph.

Therefore,  $S$  of a substance at a given temperature is an *absolute* value. As with other thermodynamic variables,

- We compare entropy values for substances at the temperature of interest in their *standard states*: 1 atm for gases, 1 M for solutions, and the pure substance in its most stable form for solids or liquids.
- Because entropy is an *extensive* property—one that depends on the amount of substance—we specify the **standard molar entropy** ( $S^\circ$ ), in units of J/mol·K (or J mol<sup>-1</sup> K<sup>-1</sup>). ( $S^\circ$  values at 298 K for many elements, compounds, and ions appear, with other thermodynamic variables, in Appendix B.)

## Predicting Relative $S^\circ$ of a System

Let's see how the standard molar entropy of a substance is affected by several parameters: temperature, physical state, dissolution, and atomic size or molecular complexity. (Unless stated otherwise, the  $S^\circ$  values refer to the system at 298 K.)

**Temperature Changes** Temperature has a direct effect on entropy:

- For any substance,  $S^\circ$  increases as  $T$  rises.

This trend is shown by the entropy values for copper metal at three temperatures:

$T$ (K):	273	295	298
$S^\circ$ (J/mol·K):	31.0	32.9	33.2

As heat is absorbed ( $q > 0$ ), temperature, which is a measure of the average kinetic energy of the particles, increases. Recall that the kinetic energies of gas particles are distributed over a range, which becomes wider as  $T$  rises (Figure 5.14); liquids and solids behave the same. Thus, at any instant, at a higher temperature, there are more microstates available in which the energy can be dispersed, so the entropy of the substance goes up. Figure 20.6 presents three ways to view the effect of temperature on entropy.

**Physical States and Phase Changes** In melting or vaporizing, heat is absorbed ( $q > 0$ ). The particles have more freedom of motion, and their energy is more dispersed. Thus,

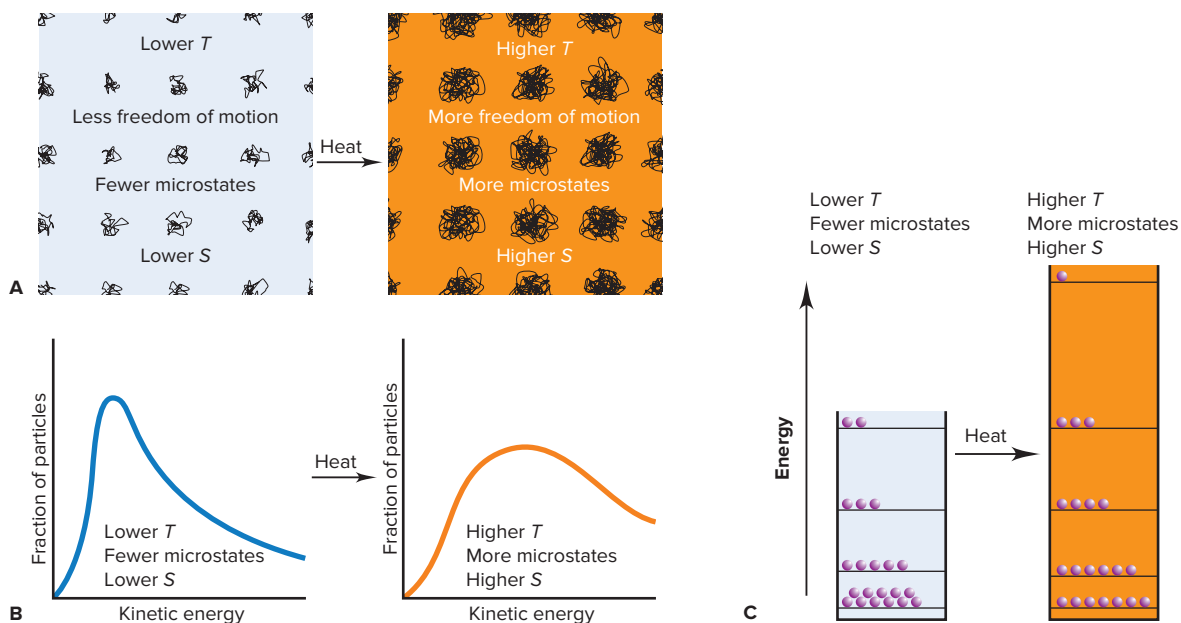

- $S^\circ$  increases as the physical state of a substance changes from solid to liquid to gas:

$$S^\circ_{\text{solid}} < S^\circ_{\text{liquid}} < S^\circ_{\text{gas}}$$

$S^\circ$ (J/mol·K)	Na	H <sub>2</sub> O	C(graphite)
$S^\circ(s \text{ or } l)$ :	51.4(s)	69.9(l)	5.7(s)
$S^\circ(g)$ :	153.6	188.7	158.0

Figure 20.7 plots entropy versus  $T$  as solid O<sub>2</sub> is heated and changes to liquid and then to gas, with  $S^\circ$  values at various points; this behavior is typical of many substances. At the molecular scale, several stages occur:

- Particles in the solid vibrate about their positions but, on average, remain fixed. The energy of the solid is dispersed least, that is, has the fewest available microstates, so the solid has the lowest entropy.
- As  $T$  rises, the entropy increases gradually as the particles' kinetic energy increases.

**Figure 20.6** Visualizing the effect of temperature on entropy. **A**, Computer simulations show each particle in a crystal moving about its lattice position. Adding heat increases  $T$  and the total energy, so the particles have greater freedom of motion, and their energy is more dispersed. Thus,  $S$  increases. **B**, At any  $T$ , there is a range of occupied energy levels and, thus, a certain number of microstates. Adding heat increases the total energy (area under curve), so the range of occupied energy levels becomes greater, as does the number of microstates (higher  $S$ ). **C**, A system consisting of 21 particles that occupy energy levels (lines) in a box whose height represents the total energy. When heat is added, the total energy increases (box is higher) and becomes more dispersed (more lines), so  $S$  increases.

- When the solid melts, the particles move much more freely between and around each other, so there is an abrupt increase in entropy ( $\Delta S_{\text{fus}}^{\circ}$ ).
- Further heating of the liquid increases the speed of the particles, and the entropy increases gradually.
- When the liquid vaporizes and becomes a gas, the particles undergo a much larger, abrupt entropy increase ( $\Delta S_{\text{vap}}^{\circ}$ ); the increase in entropy from liquid to gas is much larger than from solid to liquid:  $\Delta S_{\text{vap}}^{\circ} \gg \Delta S_{\text{fus}}^{\circ}$ .
- Finally, with further heating of the gas, the entropy increases gradually.

**Figure 20.7** The increase in entropy during phase changes from solid to liquid to gas. The data shown are for 1 mol of  $\text{O}_2$ .

**Figure 20.8** The entropy change accompanying the dissolution of a salt. The entropy of a salt solution is usually *greater* than that of the solid and of water, but it is affected by water molecules becoming organized around each ion.

**Dissolving a Solid or a Liquid in Water** Recall from Chapter 13 that, in general,

- *Entropy increases when a solid or liquid solute dissolves in a solvent:*  
 $S_{\text{soln}} > (S_{\text{solute}} + S_{\text{solvent}})$ .

But, when water is the solvent, the entropy may also depend on the nature of solute and solvent interactions, which can involve two opposing events:

1. *For ionic solutes*, when the crystal dissolves in water, the ions have much more freedom of motion and their energy is dispersed into more microstates. That is, the entropy of the ions themselves is greater in the solution. However, water molecules become arranged around the ions (Figure 20.8), which limits the molecules' freedom of motion (see also Figure 13.2). In fact, around small, multiply charged ions,  $\text{H}_2\text{O}$  molecules become so organized that their energy of motion becomes *less* dispersed. This negative portion of the total entropy change can lead to *negative*  $S^\circ$  values for the ions in solution. In the case of  $\text{AlCl}_3$ , the  $\text{Al}^{3+}(\text{aq})$  ion has such a negative  $S^\circ$  value ( $-313 \text{ J/mol}\cdot\text{K}$ ) that when  $\text{AlCl}_3$  dissolves in water, even though  $S^\circ$  of  $\text{Cl}^-(\text{aq})$  is positive, the entropy of aqueous  $\text{AlCl}_3$  is lower than that of solid  $\text{AlCl}_3$ .\*

$S^\circ$ (J/mol·K)	NaCl	$\text{AlCl}_3$	$\text{CH}_3\text{OH}$
$S^\circ(\text{s or l})$ :	72.1(s)	167(s)	127(l)
$S^\circ(\text{aq})$ :	115.1	-148	132

2. *For molecular solutes*, the increase in entropy upon dissolving is typically much smaller than for ionic solutes. After all, for a solid such as glucose, there is no separation into ions, and for a liquid such as methanol or ethanol (Figure 20.9), there is no breakdown of a crystal structure. Furthermore, in these small alcohols, as in pure water, the molecules form many H bonds, so there is relatively little change in their freedom of motion either before or after they are mixed.

**Figure 20.9** The small increase in entropy when ethanol dissolves in water. In pure ethanol (A) and pure water (B), molecules form many H bonds to other like molecules. C, In solution, these two kinds of molecules form H bonds to each other, so their freedom of motion does not change significantly.

**Dissolving a Gas in a Liquid** The particles in a gas already have so much freedom of motion—and, thus, such highly dispersed energy—that they lose some when they dissolve in a liquid or solid. Therefore,

- *The entropy of a solution of a gas in a liquid or a solid is always less than the entropy of the gas itself.*

For instance, when gaseous  $\text{O}_2$  [ $S^\circ(\text{g}) = 205.0 \text{ J/mol}\cdot\text{K}$ ] dissolves in water, its entropy decreases considerably [ $S^\circ(\text{aq}) = 110.9 \text{ J/mol}\cdot\text{K}$ ] (Figure 20.10).

When a gas dissolves in another gas, however, the entropy increases as a result of the separation and mixing of the molecules.

\*An  $S^\circ$  value for a hydrated ion can be negative because such a value is relative to the  $S^\circ$  value for the hydrated proton,  $\text{H}^+(\text{aq})$ , which is assigned a value of 0. In other words,  $\text{Al}^{3+}(\text{aq})$  has a lower entropy than  $\text{H}^+(\text{aq})$ .

**Figure 20.10** The entropy of a gas dissolved in a liquid.

**Atomic Size and Molecular Complexity** Differences in  $S^\circ$  values for substances in the same phase are usually based on atomic size and molecular complexity.

1. *Within a periodic group*, energy levels become closer together for heavier atoms, so the number of microstates, and thus the molar entropy, increases:

	Li	Na	K	Rb	Cs
Molar mass (g/mol):	6.941	22.99	39.10	85.47	132.9
$S^\circ(s)$ (J/mol·K):	29.1	51.4	64.7	69.5	85.2

The same trend of increasing entropy holds for similar compounds down a group:

	HF	HCl	HBr	HI
Molar mass (g/mol):	20.01	36.46	80.91	127.9
$S^\circ(g)$ (J/mol·K):	173.7	186.8	198.6	206.3

2. *For different forms of an element (allotropes)*, the entropy is *higher* in the form that allows the atoms more freedom of motion. For example,  $S^\circ$  of graphite is 5.69 J/mol·K, whereas  $S^\circ$  of diamond is 2.44 J/mol·K. In graphite, covalent bonds extend within a two-dimensional sheet, and the sheets move past each other relatively easily; in diamond, covalent bonds extend in three dimensions, allowing the atoms little movement (Table 12.6).

3. *For compounds*, entropy increases with chemical complexity (that is, with number of atoms in the formula), and this trend holds for ionic and covalent substances:

$S^\circ$ (J/mol·K)	NaCl	AlCl <sub>3</sub>	P <sub>4</sub> O <sub>10</sub>	NO	NO <sub>2</sub>	N <sub>2</sub> O <sub>4</sub>
$S^\circ(s)$ :	72.1	167	229			
$S^\circ(g)$ :				211	240	304

The trend is also based on the different motions that are available. Thus, for example, among the three nitrogen oxides listed in the preceding table, the number of different vibrational motions increases with the number of atoms in the molecule (Figure 20.11; see also the Tools of the Laboratory in Chapter 9).

For larger compounds, we also consider the motion of different parts of a molecule. A long hydrocarbon chain can rotate and vibrate in more ways than a short one, so *entropy increases with chain length*. A ring compound, such as cyclopentane (C<sub>5</sub>H<sub>10</sub>), has lower entropy than the chain compound with the same molar mass, pentene (C<sub>5</sub>H<sub>10</sub>), because the ring structure restricts freedom of motion:

	CH <sub>4</sub> (g)	C <sub>2</sub> H <sub>6</sub> (g)	C <sub>3</sub> H <sub>8</sub> (g)	C <sub>4</sub> H <sub>10</sub> (g)	C <sub>5</sub> H <sub>10</sub> (g)	C <sub>5</sub> H <sub>10</sub> (cyclo, g)	C <sub>2</sub> H <sub>5</sub> OH(l)
$S$ (J/mol·K):	186	230	270	310	348	293	161

Remember, these trends hold only for *substances in the same physical state*. Gaseous methane (CH<sub>4</sub>) has higher entropy than liquid ethanol (C<sub>2</sub>H<sub>5</sub>OH), even though ethanol molecules are more complex. When gases are compared with liquids, *the effect of physical state dominates the effect of molecular complexity*.

**Figure 20.11** Entropy, vibrational motion, and molecular complexity.

### SAMPLE PROBLEM 20.4

### Predicting Relative Entropy Values

**Problem** Select the substance with the higher entropy in each pair, and explain your choice [assume constant temperature, except in part (e)]:

- 1 mol of SO<sub>2</sub>(g) or 1 mol of SO<sub>3</sub>(g)
- 1 mol of CO<sub>2</sub>(s) or 1 mol of CO<sub>2</sub>(g)
- 3 mol of O<sub>2</sub>(g) or 2 mol of O<sub>3</sub>(g)
- 1 mol of KBr(s) or 1 mol of KBr(aq)
- Seawater at 2°C or at 23°C
- 1 mol of CF<sub>4</sub>(g) or 1 mol of CCl<sub>4</sub>(g)

**Plan** In general, particles with more freedom of motion have more microstates in which to disperse their kinetic energy, so they have higher entropy. We know that either

raising temperature or having *more* particles increases entropy. We apply the general categories described in the text to choose the member with the higher entropy.

**Solution** (a) 1 mol of  $\text{SO}_3(g)$ . For equal numbers of moles of substances with the same types of atoms in the same physical state, the more atoms in the molecule, the more types of motion available, and thus the higher the entropy.

(b) 1 mol of  $\text{CO}_2(g)$ . For a given substance, entropy increases in the sequence  $s < l < g$ .

(c) 3 mol of  $\text{O}_2(g)$ . The two samples contain the same number of oxygen atoms but different numbers of molecules. Despite the greater complexity of  $\text{O}_3$ , the greater number of molecules dominates because there are many more microstates possible for 3 mol of particles than for 2 mol.

(d) 1 mol of  $\text{KBr}(aq)$ . The two samples have the same number of ions, but their motion is more limited and their energy less dispersed in the solid than in the solution.

(e) Seawater at  $23^\circ\text{C}$ . Entropy increases with rising temperature.

(f) 1 mol of  $\text{CCl}_4(g)$ . For similar compounds, entropy increases with molar mass.

### FOLLOW-UP PROBLEMS

**20.4A** Select the substance with the *higher* entropy in each pair, and explain your choice (assume 1 mol of each at the same  $T$ ):

(a)  $\text{PCl}_3(g)$  or  $\text{PCl}_5(g)$     (b)  $\text{CaF}_2(s)$  or  $\text{BaCl}_2(s)$     (c)  $\text{Br}_2(g)$  or  $\text{Br}_2(l)$

**20.4B** Select the substance with the *lower* entropy in each pair, and explain your choice (assume 1 mol of each at the same  $T$ ):

(a)  $\text{LiBr}(aq)$  or  $\text{NaBr}(aq)$     (b) quartz or glass    (c)  $\text{H}_2\text{C}-\text{CH}-\text{CH}_2-\text{CH}_3$  or

**SOME SIMILAR PROBLEMS** 20.22–20.29

### Student Hot Spot

Student data indicate that you may struggle with entropy trends. Access the Smartbook to view additional Learning Resources on this topic.

## › Summary of Section 20.1

- › A change is spontaneous under specified conditions if it occurs without a continuous input of energy.
- › Neither the first law of thermodynamics nor the sign of  $\Delta H$  predicts the direction of a spontaneous change.
- › Many spontaneous processes involve an increase in the freedom of motion of the system's particles and, thus, in the dispersal of the system's energy of motion.
- › Entropy is a state function that measures the extent of energy dispersed into the number of microstates possible for a system. Each microstate consists of the quantized energy levels of the system at a given instant.
- › The entropy change that occurs during an isothermal change in gas volume, during a phase change, or during a temperature change can be calculated.
- › The second law of thermodynamics states that, in a spontaneous process, the entropy of the universe (system plus surroundings) increases.
- › Absolute entropy values can be determined because perfect crystals have zero entropy at 0 K (third law of thermodynamics).
- › Standard molar entropy,  $S^\circ$  (in  $\text{J}/\text{mol}\cdot\text{K}$ ), is affected by temperature, phase changes, dissolution, and atomic size or molecular complexity.

## 20.2 CALCULATING THE CHANGE IN ENTROPY OF A REACTION

Chemists are especially interested in learning how to predict the sign *and* calculate the value of the entropy change that occurs during a reaction.

### Entropy Changes in the System: Standard Entropy of Reaction ( $\Delta S^\circ_{\text{rxn}}$ )

The **standard entropy of reaction**,  $\Delta S^\circ_{\text{rxn}}$ , is the entropy change that occurs when all reactants and products are in their standard states.

**Predicting the Sign of  $\Delta S_{\text{rxn}}^{\circ}$**  Changes in structure and especially in amount (mol) of a gas help us predict the sign of  $\Delta S_{\text{rxn}}^{\circ}$ . Because gases have such great freedom of motion and, thus, high molar entropies, *if the number of moles of gas increases,  $\Delta S_{\text{rxn}}^{\circ}$  is positive; if the number decreases,  $\Delta S_{\text{rxn}}^{\circ}$  is negative.* Here are a few examples:

- *Increase in amount of gas.* When gaseous  $\text{H}_2$  reacts with solid  $\text{I}_2$  to form gaseous  $\text{HI}$ , the total number of moles of *substance* stays the same. Nevertheless, the sign of  $\Delta S_{\text{rxn}}^{\circ}$  is positive (entropy increases) because the number of moles of *gas* increases:

- *Decrease in amount of gas.* When ammonia forms from its elements, 4 mol of gas produce 2 mol of gas, so  $\Delta S_{\text{rxn}}^{\circ}$  is negative (entropy decreases):

- *No change in amount of gas, but change in structure.* When the amount (mol) of gas doesn't change, we *cannot* predict the sign of  $\Delta S_{\text{rxn}}^{\circ}$ . But, a change in one of the structures can make it easier to predict the sign of  $\Delta S_{\text{rxn}}^{\circ}$ . For example, when cyclopropane is heated to  $500^{\circ}\text{C}$ , the ring opens and propene forms. The chain has more freedom of motion than the ring, so  $\Delta S_{\text{rxn}}^{\circ}$  is positive:

Keep in mind, however, that in general we *cannot predict the sign of the entropy change unless the reaction involves a change in number of moles of gas.*

**Calculating  $\Delta S_{\text{rxn}}^{\circ}$  from  $S^{\circ}$  Values** By applying Hess's law (Chapter 6), we combined  $\Delta H_f^{\circ}$  values to find  $\Delta H_{\text{rxn}}^{\circ}$ . Similarly, we combine  $S^{\circ}$  values to find the standard entropy of reaction,  $\Delta S_{\text{rxn}}^{\circ}$ :

$$\Delta S_{\text{rxn}}^{\circ} = \sum m S_{\text{products}}^{\circ} - \sum n S_{\text{reactants}}^{\circ} \quad (20.9)$$

where  $m$  and  $n$  are the amounts (mol) of products and reactants, respectively, given by the coefficients in the balanced equation. For the formation of ammonia, we have

$$\Delta S_{\text{rxn}}^{\circ} = [(2 \text{ mol NH}_3)(S^{\circ} \text{ of NH}_3)] - [(1 \text{ mol N}_2)(S^{\circ} \text{ of N}_2) + (3 \text{ mol H}_2)(S^{\circ} \text{ of H}_2)]$$

From Appendix B, we find the  $S^{\circ}$  values:

$$\begin{aligned} \Delta S_{\text{rxn}}^{\circ} &= [(2 \text{ mol})(193 \text{ J/mol}\cdot\text{K})] - [(1 \text{ mol})(191.5 \text{ J/mol}\cdot\text{K}) + (3 \text{ mol})(130.6 \text{ J/mol}\cdot\text{K})] \\ &= -197 \text{ J/K} \end{aligned}$$

As we predicted above from the decrease in number of moles of gas,  $\Delta S_{\text{rxn}}^{\circ} < 0$ .

### SAMPLE PROBLEM 20.5

### Calculating the Standard Entropy of Reaction, $\Delta S_{\text{rxn}}^{\circ}$

**Problem** Predict the sign of  $\Delta S_{\text{rxn}}^{\circ}$ , if possible, and calculate its value for the combustion of 1 mol of propane at  $25^{\circ}\text{C}$ :

**Plan** We use the change in the number of moles of gas to predict the sign of  $\Delta S_{\text{rxn}}^{\circ}$ . To find  $\Delta S_{\text{rxn}}^{\circ}$ , we apply Equation 20.9.

**Solution** The amount (mol) of gas decreases (6 mol of reactant gas yields 3 mol of product gas), so the entropy should decrease ( $\Delta S_{\text{rxn}}^{\circ} < 0$ ).

Calculating  $\Delta S_{\text{rxn}}^{\circ}$ . Using Appendix B values,

$$\begin{aligned} \Delta S_{\text{rxn}}^{\circ} &= [(3 \text{ mol CO}_2)(S^{\circ} \text{ of CO}_2) + (4 \text{ mol H}_2\text{O})(S^{\circ} \text{ of H}_2\text{O})] \\ &\quad - [(1 \text{ mol C}_3\text{H}_8)(S^{\circ} \text{ of C}_3\text{H}_8) + (5 \text{ mol O}_2)(S^{\circ} \text{ of O}_2)] \\ &= [(3 \text{ mol})(213.7 \text{ J/mol}\cdot\text{K}) + (4 \text{ mol})(69.940 \text{ J/mol}\cdot\text{K})] \\ &\quad - [(1 \text{ mol})(269.9 \text{ J/mol}\cdot\text{K}) + (5 \text{ mol})(205.0 \text{ J/mol}\cdot\text{K})] \\ &= \mathbf{-374.0 \text{ J/K}} \end{aligned}$$

**Check**  $\Delta S_{\text{rxn}}^{\circ} < 0$ , so our prediction is correct. Rounding gives  $[3(200) + 4(70)] - [270 + 5(200)] = 880 - 1270 = -390$ , close to the calculated value.

**Comment** Notice that there are 6 mol of reactants and 7 mol of products in the propane combustion reaction; however, we do not count the 4 mol of  $\text{H}_2\text{O}(l)$  when we look for an increase or decrease in mol of gas to predict  $\Delta S_{\text{rxn}}^{\circ}$ .

### FOLLOW-UP PROBLEMS

**20.5A** Balance each equation, predict the sign of  $\Delta S_{\text{rxn}}^{\circ}$  if possible, and calculate its value at 298 K:

**20.5B** Balance each equation, predict the sign of  $\Delta S_{\text{rxn}}^{\circ}$  if possible, and calculate its value at 25°C:

**SOME SIMILAR PROBLEMS** 20.33–20.38

## Entropy Changes in the Surroundings: The Other Part of the Total

In the synthesis of ammonia, the combustion of propane, and many other spontaneous reactions, the entropy of the *system* decreases ( $\Delta S_{\text{rxn}}^{\circ} < 0$ ). Remember that the second law dictates that, for a spontaneous process, a *decrease in the entropy of the system is outweighed by an increase in the entropy of the surroundings*. In this section, we examine the influence of the surroundings—in particular, the addition (or removal) of heat and the temperature at which this heat flow occurs—on the *total* entropy change.

**The Role of the Surroundings** In essence, the surroundings *add heat to or remove heat from the system*. That is, the surroundings function as an enormous heat source or heat sink, one so large that its temperature remains constant, even though its entropy changes. The surroundings participate in the two types of enthalpy changes as follows:

1. *In an exothermic change, heat released by the system is absorbed by the surroundings.* More heat increases the freedom of motion of the particles and makes the energy more dispersed, so the entropy of the surroundings increases:

$$\text{For an exothermic change: } q_{\text{sys}} < 0, \quad q_{\text{surr}} > 0, \quad \text{and} \quad \Delta S_{\text{surr}} > 0$$

2. *In an endothermic change, heat absorbed by the system is released by the surroundings.* Less heat reduces the freedom of motion of the particles and makes the energy less dispersed, so the entropy of the surroundings decreases:

$$\text{For an endothermic change: } q_{\text{sys}} > 0, \quad q_{\text{surr}} < 0, \quad \text{and} \quad \Delta S_{\text{surr}} < 0$$

**Temperature at Which Heat Is Transferred** The *temperature* of the surroundings when the heat is transferred also affects  $\Delta S_{\text{surr}}$ . Consider the effect of an exothermic reaction at a low or at a high temperature:

- At a low  $T$ , such as 20 K, there is little motion of particles in the surroundings because they have relatively low energy. This means there are few energy levels in each microstate and few microstates in which to disperse the energy. Transferring a given quantity of heat to these surroundings causes a relatively large change in how much energy is dispersed.
- At a high  $T$ , such as 298 K, the surroundings have a large quantity of energy dispersed among the particles. There are more energy levels in each microstate and a greater number of microstates. Transferring the same given quantity of heat to these surroundings causes a relatively small change in how much energy is dispersed. ◀

### A Checkbook Analogy for Heating the Surroundings

If you have \$10 in your checking account, a \$10 deposit represents a 100% increase in your net worth; that is, a given change to a low initial state has a large impact. If, however, you have a \$1000 balance, a \$10 deposit represents only a 1% increase. Thus, the same absolute change to a high initial state has a smaller impact.

In other words,  $\Delta S_{\text{surr}}$  is greater when heat is added at a lower  $T$ . Putting these ideas together,  $\Delta S_{\text{surr}}$  is directly related to an opposite change in the heat of the system ( $q_{\text{sys}}$ ) and inversely related to the temperature at which the heat is transferred:

$$\Delta S_{\text{surr}} = -\frac{q_{\text{sys}}}{T}$$

For a process at constant pressure, the heat ( $q_p$ ) is  $\Delta H$  (Section 6.2), so

$$\Delta S_{\text{surr}} = -\frac{\Delta H_{\text{sys}}}{T} \quad (20.10)$$

Thus, we find  $\Delta S_{\text{surr}}$  by measuring  $\Delta H_{\text{sys}}$  and  $T$  at which the change takes place.

*The main point:* If a spontaneous reaction has a negative  $\Delta S_{\text{sys}}$  (fewer microstates into which energy is dispersed),  $\Delta S_{\text{surr}}$  must be positive enough (even more microstates into which energy is dispersed) for  $\Delta S_{\text{univ}}$  to be positive (net increase in number of microstates for dispersing the energy).

### SAMPLE PROBLEM 20.6

### Determining Reaction Spontaneity

**Problem** At 298 K, the formation of ammonia has a negative  $\Delta S_{\text{sys}}^{\circ}$ :

Calculate  $\Delta S_{\text{univ}}$ , and state whether the reaction occurs spontaneously at this temperature.

**Plan** For the reaction to occur spontaneously,  $\Delta S_{\text{univ}} > 0$ , so  $\Delta S_{\text{surr}}$  must be greater than  $+197 \text{ J/K}$ . To find  $\Delta S_{\text{surr}}$ , we need  $\Delta H_{\text{sys}}^{\circ}$ , which is the same as  $\Delta H_{\text{rxn}}^{\circ}$ . We use  $\Delta H_{\text{f}}^{\circ}$  values from Appendix B to find  $\Delta H_{\text{rxn}}^{\circ}$ . Then, we divide  $\Delta H_{\text{rxn}}^{\circ}$  by the given  $T$  (298 K) to find  $\Delta S_{\text{surr}}$ . To find  $\Delta S_{\text{univ}}$ , we add the calculated  $\Delta S_{\text{surr}}$  to the given  $\Delta S_{\text{sys}}^{\circ}$  ( $-197 \text{ J/K}$ ).

**Solution** Calculating  $\Delta H_{\text{sys}}^{\circ}$ :

$$\begin{aligned} \Delta H_{\text{sys}}^{\circ} &= \Delta H_{\text{rxn}}^{\circ} \\ &= [(2 \text{ mol NH}_3)(\Delta H_{\text{f}}^{\circ} \text{ of NH}_3)] - [(3 \text{ mol H}_2)(\Delta H_{\text{f}}^{\circ} \text{ of H}_2) + (1 \text{ mol N}_2)(\Delta H_{\text{f}}^{\circ} \text{ of N}_2)] \\ &= [(2 \text{ mol NH}_3)(-45.9 \text{ kJ/mol})] - [(3 \text{ mol H}_2)(0 \text{ kJ/mol}) + (1 \text{ mol N}_2)(0 \text{ kJ/mol})] \\ &= -91.8 \text{ kJ} \end{aligned}$$

Calculating  $\Delta S_{\text{surr}}$ :

$$\Delta S_{\text{surr}} = -\frac{\Delta H_{\text{sys}}^{\circ}}{T} = -\frac{-91.8 \text{ kJ} \times \frac{1000 \text{ J}}{1 \text{ kJ}}}{298 \text{ K}} = 308 \text{ J/K}$$

Determining  $\Delta S_{\text{univ}}$ :

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}}^{\circ} + \Delta S_{\text{surr}} = -197 \text{ J/K} + 308 \text{ J/K} = 111 \text{ J/K}$$

Since  $\Delta S_{\text{univ}} > 0$ , the reaction occurs spontaneously at 298 K (see margin).

**Check** Rounding to check the math, we have

$$\begin{aligned} \Delta H_{\text{rxn}}^{\circ} &\approx 2(-45 \text{ kJ}) = -90 \text{ kJ} \\ \Delta S_{\text{surr}} &\approx -(-90,000 \text{ J})/300 \text{ K} = 300 \text{ J/K} \\ \Delta S_{\text{univ}} &\approx -200 \text{ J/K} + 300 \text{ J/K} = 100 \text{ J/K} \end{aligned}$$

Given the negative  $\Delta H_{\text{rxn}}^{\circ}$ , Le Châtelier's principle says that low  $T$  favors  $\text{NH}_3$  formation, so the answer is reasonable (see Section 17.6).

**Comment 1.** Because  $\Delta H^{\circ}$  has units of kJ, and  $\Delta S$  has units of J/K, don't forget to convert kJ to J, or you'll introduce a large error.

**2.** This example highlights the distinction between thermodynamics and kinetics.  $\text{NH}_3$  forms spontaneously, but so slowly that catalysts are required to achieve a practical rate.

## FOLLOW-UP PROBLEMS

**20.6A** Gaseous phosphorus trichloride forms from the elements through this reaction:

Calculate  $\Delta H_{\text{rxn}}^\circ$ ,  $\Delta S_{\text{surr}}^\circ$ , and  $\Delta S_{\text{rxn}}^\circ$  to determine if the reaction is spontaneous at 298 K.

**20.6B** Does the oxidation of  $\text{FeO}(\text{s})$  to  $\text{Fe}_2\text{O}_3(\text{s})$  occur spontaneously at 298 K? (Show the calculation for 1 mol of  $\text{Fe}_2\text{O}_3$ .)

**SOME SIMILAR PROBLEMS** 20.39–20.42

**Do Organisms Obey the Laws of Thermodynamics?** Taking the surroundings into account is crucial, not only for determining reaction spontaneity, as in Sample Problem 20.6, but also for understanding the relevance of thermodynamics to biology. Let's examine the first and second laws to see if they apply to living systems.

1. *Do organisms comply with the first law?* The chemical bond energy in food and oxygen is converted into the mechanical energy of jumping, flying, crawling, swimming, and countless other movements; the electrical energy of nerve conduction; the thermal energy of warming the body; and so forth. Many experiments have demonstrated that the total energy is conserved in these situations. Some of the earliest were performed by Lavoisier, who showed that “animal heat” was produced by slow, continual combustion. In experiments with guinea pigs, he invented a calorimeter to measure the heat released from intake of food and  $\text{O}_2$  and output of  $\text{CO}_2$  and water, and he included respiration in his new theory of combustion. Modern, room-sized calorimeters measure these and other variables to confirm the conservation of energy for an exercising human (Figure 20.12).

2. *Do organisms comply with the second law?* Mature humans are far more complex than the egg and sperm cells from which they develop, and modern organisms are far more complex than the one-celled ancestral specks from which they evolved. Are the growth of an organism and the evolution of life exceptions to the spontaneous tendency of natural processes to increase freedom of motion and disperse energy? For an organism to grow or a species to evolve, many moles of oxygen and nutrients—carbohydrates, proteins, and fats—undergo exothermic reactions to form many *more* moles of gaseous  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . Formation of these waste gases and the accompanying release of heat result in an enormous *increase* in the entropy of the surroundings. Thus, the localization of energy and synthesis of macromolecular structures required for the growth and evolution of organisms (system) cause a far greater dispersal of energy and freedom of motion in the environment (surroundings). When system *and* surroundings are considered together, the entropy of the universe, as always, increases.

**Figure 20.12** A whole-body calorimeter. In this room-sized apparatus, a person exercises while respiratory gases, energy input and output, and other physiological variables are monitored.

## The Entropy Change and the Equilibrium State

For a process approaching equilibrium,  $\Delta S_{\text{univ}} > 0$ . When the process reaches equilibrium, there is no further *net* change,  $\Delta S_{\text{univ}} = 0$ , because any entropy change in the system is balanced by an opposite entropy change in the surroundings:

$$\text{At equilibrium: } \Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = 0 \quad \text{so} \quad \Delta S_{\text{sys}} = -\Delta S_{\text{surr}}$$

As an example, let's calculate  $\Delta S_{\text{univ}}$  for the vaporization-condensation of 1 mol of water at  $100^\circ\text{C}$  (373 K),

First, we find  $\Delta S_{\text{sys}}^\circ$  for the forward change (vaporization) of 1 mol of water:

$$\begin{aligned} \Delta S_{\text{sys}}^\circ &= \sum m S_{\text{products}}^\circ - \sum n S_{\text{reactants}}^\circ = S^\circ \text{ of } \text{H}_2\text{O}(\text{g}; 373 \text{ K}) - S^\circ \text{ of } \text{H}_2\text{O}(\text{l}; 373 \text{ K}) \\ &= 195.9 \text{ J/K} - 86.8 \text{ J/K} = 109.1 \text{ J/K} \end{aligned}$$

As we expect, the entropy of the system increases ( $\Delta S_{\text{sys}}^\circ > 0$ ) as the liquid absorbs heat and changes to a gas.

For  $\Delta S_{\text{surr}}$  of the vaporization step, we have

$$\Delta S_{\text{surr}} = -\frac{\Delta H_{\text{sys}}^{\circ}}{T}$$

where  $\Delta H_{\text{sys}}^{\circ} = \Delta H_{\text{vap}}^{\circ}$  at 373 K = 40.7 kJ/mol =  $40.7 \times 10^3$  J/mol. For 1 mol of water, we have

$$\Delta S_{\text{surr}} = -\frac{\Delta H_{\text{vap}}^{\circ}}{T} = -\frac{40.7 \times 10^3 \text{ J}}{373 \text{ K}} = -109 \text{ J/K}$$

The surroundings lose heat, and the negative sign means that the entropy of the surroundings decreases. The two entropy changes have the same magnitude but opposite signs, so they cancel:

$$\Delta S_{\text{univ}} = 109 \text{ J/K} + (-109 \text{ J/K}) = 0$$

For the reverse change (condensation),  $\Delta S_{\text{univ}}$  also equals zero, but  $\Delta S_{\text{sys}}^{\circ}$  and  $\Delta S_{\text{surr}}$  have signs opposite those for vaporization.

A similar treatment of a chemical change shows the same result: the entropy change of the forward reaction is *equal in magnitude but opposite in sign* to the entropy change of the reverse reaction. Thus, *when a system reaches equilibrium, neither the forward nor the reverse reaction is spontaneous*, and so there is no net reaction in either direction.

## Spontaneous Exothermic and Endothermic Changes

No matter what its *enthalpy* change, a reaction occurs because the total *entropy* of the reacting system *and* its surroundings increases. There are two ways this can happen:

1. *In an exothermic reaction* ( $\Delta H_{\text{sys}} < 0$ ), the heat released by the system increases the freedom of motion and dispersal of energy in the surroundings; thus,  $\Delta S_{\text{surr}} > 0$ .

- If the entropy of the products is *more* than that of the reactants ( $\Delta S_{\text{sys}} > 0$ ), the total entropy change ( $\Delta S_{\text{sys}} + \Delta S_{\text{surr}}$ ) will be positive (Figure 20.13A). For example, in the oxidation of glucose, an essential reaction for all higher organisms,

6 mol of gas yields 12 mol of gas; thus,  $\Delta S_{\text{sys}} > 0$ ,  $\Delta S_{\text{surr}} > 0$ , and  $\Delta S_{\text{univ}} > 0$ .

- If the entropy of the products is *less* than that of the reactants ( $\Delta S_{\text{sys}} < 0$ ), the entropy of the surroundings must increase even more ( $\Delta S_{\text{surr}} \gg 0$ ) to make the total  $\Delta S$  positive (Figure 20.13B). For example, when calcium oxide and carbon dioxide form calcium carbonate, the amount (mol) of gas decreases from 1 to 0:

However, even though the system's entropy goes down, the heat released increases the entropy of the surroundings even more; thus,  $\Delta S_{\text{sys}} < 0$ , but  $\Delta S_{\text{surr}} \gg 0$ , so  $\Delta S_{\text{univ}} > 0$ .

2. *In an endothermic reaction* ( $\Delta H_{\text{sys}} > 0$ ), the heat absorbed by the system decreases molecular freedom of motion and dispersal of energy in the surroundings;

**Figure 20.13** Components of  $\Delta S_{\text{univ}}$  for spontaneous reactions. For a reaction to occur spontaneously,  $\Delta S_{\text{univ}}$  must be positive. **A**, An exothermic reaction in which  $\Delta S_{\text{sys}}$  increases; the size of  $\Delta S_{\text{surr}}$  is not important. **B**, An exothermic reaction in which  $\Delta S_{\text{sys}}$  decreases;  $\Delta S_{\text{surr}}$  must be larger than  $\Delta S_{\text{sys}}$ . **C**, An endothermic reaction in which  $\Delta S_{\text{sys}}$  increases;  $\Delta S_{\text{surr}}$  must be smaller than  $\Delta S_{\text{sys}}$ .

so  $\Delta S_{\text{surr}} < 0$ . Thus, the only way an endothermic reaction can occur spontaneously is if  $\Delta S_{\text{sys}}$  is positive and large enough to outweigh the negative  $\Delta S_{\text{surr}}$  (Figure 20.13C).

- In the solution process for many ionic compounds, heat is absorbed to form the solution, so the entropy of the surroundings decreases ( $\Delta S_{\text{surr}} < 0$ ). However, when the crystalline solid becomes freely moving ions, the entropy increase is so large ( $\Delta S_{\text{sys}} \gg 0$ ) that it outweighs the negative  $\Delta S_{\text{surr}}$ . Thus,  $\Delta S_{\text{univ}}$  is positive.
- Spontaneous endothermic reactions are similar. Recall the reaction between barium hydroxide octahydrate and ammonium nitrate (Figure 20.1),

3 mol of crystalline solids absorb heat from the surroundings ( $\Delta S_{\text{surr}} < 0$ ) and yields 15 mol of dissolved ions and molecules, which have much more freedom of motion and, therefore, much greater entropy ( $\Delta S_{\text{sys}} \gg 0$ ).

### › Summary of Section 20.2

- › The standard entropy of reaction,  $\Delta S_{\text{rxn}}^\circ$ , is calculated from  $S^\circ$  values.
- › When the amount (mol) of gas increases in a reaction, usually  $\Delta S_{\text{rxn}}^\circ > 0$ .
- › The change in entropy of the surroundings,  $\Delta S_{\text{surr}}$ , is related directly to  $-\Delta H_{\text{sys}}^\circ$  and inversely to the absolute temperature  $T$  at which the change occurs.
- › In a spontaneous change, the entropy of the system can decrease only if the entropy of the surroundings increases even more, so that  $\Delta S_{\text{univ}} > 0$ .
- › The second law is obeyed in living systems when we consider system *plus* surroundings.
- › For a system at equilibrium,  $\Delta S_{\text{univ}} = 0$ , so  $\Delta S_{\text{sys}}^\circ = -\Delta S_{\text{surr}}$ .
- › Even if  $\Delta S_{\text{sys}}^\circ < 0$ , an exothermic reaction ( $\Delta H_{\text{rxn}}^\circ < 0$ ) is spontaneous ( $\Delta S_{\text{univ}} > 0$ ) if  $\Delta S_{\text{surr}} \gg 0$ ; an endothermic reaction ( $\Delta H_{\text{rxn}}^\circ > 0$ ) is spontaneous only if  $\Delta S_{\text{sys}}^\circ > \Delta S_{\text{surr}}$ .

## 20.3 ENTROPY, FREE ENERGY, AND WORK

By measuring *both*  $\Delta S_{\text{sys}}$  and  $\Delta S_{\text{surr}}$ , we can predict whether a reaction will be spontaneous at a particular temperature. It would be useful to have *one* criterion for spontaneity that we can determine *by measuring the system only*. The Gibbs free energy, or simply **free energy** ( $G$ ), combines the system's enthalpy and entropy:

$$G = H - TS$$

One of the greatest but least recognized of American scientists, Josiah Willard Gibbs (1839–1903), established chemical thermodynamics as well as major principles of equilibrium and electrochemistry. Although the great European scientists of his time, James Clerk Maxwell and Henri Le Châtelier, realized Gibbs's achievements, he was not recognized by his American colleagues until nearly 50 years after his death!

### Free Energy Change and Reaction Spontaneity

*The free energy change ( $\Delta G$ ) is a measure of the spontaneity of a process and of the useful energy available from it.*

**Deriving the Gibbs Equation** Let's examine the meaning of  $\Delta G$  by deriving it from the second law. By definition, the entropy change of the universe is the sum of the entropy changes of the system and the surroundings:

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}}$$

At constant pressure,

$$\Delta S_{\text{surr}} = -\frac{\Delta H_{\text{sys}}}{T}$$

Substituting for  $\Delta S_{\text{surr}}$  gives a relationship that relies solely on the system:

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} - \frac{\Delta H_{\text{sys}}}{T}$$

Multiplying both sides by  $-T$  and rearranging gives

$$-T\Delta S_{\text{univ}} = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}}$$

Using the Gibbs free energy relationship,  $G = H - TS$ , we obtain the *Gibbs equation* for the *change* in the free energy of the system ( $\Delta G_{\text{sys}}$ ) at constant  $T$  and  $P$ :

$$\Delta G_{\text{sys}} = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} \quad (20.11)$$

Combining Equation 20.11 with the one preceding it shows that

$$-T\Delta S_{\text{univ}} = \Delta G_{\text{sys}} = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}}$$

**Spontaneity and the Sign of  $\Delta G$**  Let's see how the *sign* of  $\Delta G$  tells if a reaction is spontaneous. According to the second law,

- $\Delta S_{\text{univ}} > 0$  for a spontaneous process
- $\Delta S_{\text{univ}} < 0$  for a nonspontaneous process
- $\Delta S_{\text{univ}} = 0$  for a process at equilibrium

Since the absolute temperature is always positive, for a spontaneous process,

$$T\Delta S_{\text{univ}} > 0 \quad \text{so} \quad -T\Delta S_{\text{univ}} < 0$$

From our derivation above,  $\Delta G = -T\Delta S_{\text{univ}}$ , so we have

- $\Delta G < 0$  for a spontaneous process
- $\Delta G > 0$  for a nonspontaneous process
- $\Delta G = 0$  for a process at equilibrium

Without incorporating any new ideas, we can now predict spontaneity with one variable ( $\Delta G_{\text{sys}}$ ) rather than two ( $\Delta S_{\text{sys}}$  and  $\Delta S_{\text{surr}}$ ).

## Calculating Standard Free Energy Changes

The *sign* of  $\Delta G$  reveals *whether* a reaction is spontaneous, but the *magnitude* of  $\Delta G$  tells *how* spontaneous it is. Because free energy ( $G$ ) combines three state functions,  $H$ ,  $S$ , and  $T$ , it is also a state function. As we do with enthalpy, we focus on the free energy *change* ( $\Delta G$ ). As we do with other thermodynamic variables, to compare the free energy changes of different reactions, we calculate the **standard free energy change** ( $\Delta G^\circ$ ), which occurs when all components of the system are in their standard states.

**Using the Gibbs Equation to Find  $\Delta G^\circ$**  One way to calculate  $\Delta G^\circ$  is by writing the Gibbs equation (Equation 20.11) at standard-state conditions and using Appendix B to find  $\Delta H_{\text{sys}}^\circ$  and  $\Delta S_{\text{sys}}^\circ$ . Adapting the Gibbs equation, we have

$$\Delta G_{\text{sys}}^\circ = \Delta H_{\text{sys}}^\circ - T\Delta S_{\text{sys}}^\circ \quad (20.12)$$

This important relationship is used to find any one of these three variables, given the other two, as in the following sample problem.

### SAMPLE PROBLEM 20.7

#### Calculating $\Delta G_{\text{rxn}}^\circ$ from Enthalpy and Entropy Values

**Problem** Potassium chlorate, a common oxidizing agent in fireworks (see photo) and matchheads, undergoes a solid-state disproportionation reaction when heated:

Use  $\Delta H_f^\circ$  and  $S^\circ$  values to calculate  $\Delta G_{\text{sys}}^\circ$  (which is  $\Delta G_{\text{rxn}}^\circ$ ) at  $25^\circ\text{C}$  for this reaction.

**Plan** To solve for  $\Delta G^\circ$ , we need values from Appendix B. We use  $\Delta H_f^\circ$  values to calculate  $\Delta H_{\text{rxn}}^\circ$  ( $\Delta H_{\text{sys}}^\circ$ ), use  $S^\circ$  values to calculate  $\Delta S_{\text{rxn}}^\circ$  ( $\Delta S_{\text{sys}}^\circ$ ), and then apply Equation 20.12.

Fireworks explode spontaneously.  
Source: © Karl Weatherly/PhotoDisc, RF

**Solution** Calculating  $\Delta H_{\text{sys}}^{\circ}$  from  $\Delta H_{\text{f}}^{\circ}$  values (with Equation 6.10):

$$\begin{aligned}\Delta H_{\text{sys}}^{\circ} &= \Delta H_{\text{rxn}}^{\circ} = \sum m\Delta H_{\text{f}}^{\circ}(\text{products}) - \sum n\Delta H_{\text{f}}^{\circ}(\text{reactants}) \\ &= [(3 \text{ mol KClO}_4)(\Delta H_{\text{f}}^{\circ} \text{ of KClO}_4) + (1 \text{ mol KCl})(\Delta H_{\text{f}}^{\circ} \text{ of KCl})] \\ &\quad - [(4 \text{ mol KClO}_3)(\Delta H_{\text{f}}^{\circ} \text{ of KClO}_3)] \\ &= [(3 \text{ mol})(-432.75 \text{ kJ/mol}) + (1 \text{ mol})(-436.7 \text{ kJ/mol})] \\ &\quad - [(4 \text{ mol})(-397.7 \text{ kJ/mol})] \\ &= -144.2 \text{ kJ}\end{aligned}$$

Calculating  $\Delta S_{\text{sys}}^{\circ}$  from  $S^{\circ}$  values (with Equation 20.9):

$$\begin{aligned}\Delta S_{\text{sys}}^{\circ} &= \Delta S_{\text{rxn}}^{\circ} = \sum mS_{\text{products}}^{\circ} - \sum nS_{\text{reactants}}^{\circ} \\ &= [(3 \text{ mol KClO}_4)(S^{\circ} \text{ of KClO}_4) + (1 \text{ mol KCl})(S^{\circ} \text{ of KCl})] \\ &\quad - [(4 \text{ mol KClO}_3)(S^{\circ} \text{ of KClO}_3)] \\ &= [(3 \text{ mol})(151.0 \text{ J/mol}\cdot\text{K}) + (1 \text{ mol})(82.6 \text{ J/mol}\cdot\text{K})] \\ &\quad - [(4 \text{ mol})(143.1 \text{ J/mol}\cdot\text{K})] \\ &= -36.8 \text{ J/K}\end{aligned}$$

Calculating  $\Delta G_{\text{sys}}^{\circ}$  at 298 K:

$$\Delta G_{\text{sys}}^{\circ} = \Delta H_{\text{sys}}^{\circ} - T\Delta S_{\text{sys}}^{\circ} = -144.2 \text{ kJ} - \left[ (298 \text{ K})(-36.8 \text{ J/K}) \left( \frac{1 \text{ kJ}}{1000 \text{ J}} \right) \right] = -133.2 \text{ kJ}$$

**Check** Rounding to check the math:

$$\begin{aligned}\Delta H^{\circ} &\approx [3(-433 \text{ kJ}) + (-440 \text{ kJ})] - [4(-400 \text{ kJ})] = -1740 \text{ kJ} + 1600 \text{ kJ} = -140 \text{ kJ} \\ \Delta S^{\circ} &\approx [3(150 \text{ J/K}) + 85 \text{ J/K}] - [4(145 \text{ J/K})] = 535 \text{ J/K} - 580 \text{ J/K} = -45 \text{ J/K} \\ \Delta G^{\circ} &\approx -140 \text{ kJ} - 300 \text{ K}(-0.04 \text{ kJ/K}) = -140 \text{ kJ} + 12 \text{ kJ} = -128 \text{ kJ}\end{aligned}$$

**Comment 1.** Recall from Section 20.1 that reaction spontaneity tells nothing about rate. Even though this reaction is spontaneous, the rate is very low in the solid. When  $\text{KClO}_3$  is heated slightly above its melting point, the ions can move and the reaction occurs readily.  
**2.** Under *any* conditions, a spontaneous reaction has a negative change in free energy:  $\Delta G < 0$ . Under standard-state conditions, a spontaneous reaction has a negative *standard* free energy change:  $\Delta G^{\circ} < 0$ .

### FOLLOW-UP PROBLEMS

**20.7A** Use  $\Delta H_{\text{rxn}}^{\circ}$  and  $\Delta S_{\text{rxn}}^{\circ}$  to calculate  $\Delta G_{\text{rxn}}^{\circ}$  at 298 K for this reaction:

**20.7B** Determine the standard free energy change at 298 K for this reaction:

**SOME SIMILAR PROBLEMS** 20.53 and 20.54

**Using Standard Free Energies of Formation to Find  $\Delta G_{\text{rxn}}^{\circ}$**  Another way to calculate  $\Delta G_{\text{rxn}}^{\circ}$  is with values for the **standard free energy of formation ( $\Delta G_{\text{f}}^{\circ}$ )** of the components. Analogous to the standard enthalpy of formation,  $\Delta H_{\text{f}}^{\circ}$  (Section 6.6),  $\Delta G_{\text{f}}^{\circ}$  is the free energy change that occurs when 1 mol of a compound is made *from its elements*, with all components in their standard states. Because free energy is a state function, we can apply Hess's law and combine  $\Delta G_{\text{f}}^{\circ}$  values of reactants and products to calculate  $\Delta G_{\text{rxn}}^{\circ}$ , no matter how the reaction takes place:

$$\Delta G_{\text{rxn}}^{\circ} = \sum m\Delta G_{\text{f}}^{\circ}(\text{products}) - \sum n\Delta G_{\text{f}}^{\circ}(\text{reactants}) \quad (20.13)$$

$\Delta G_{\text{f}}^{\circ}$  values have properties similar to  $\Delta H_{\text{f}}^{\circ}$  values:

- $\Delta G_{\text{f}}^{\circ}$  of an element in its standard state is zero.
- A coefficient in the reaction equation ( $m$  or  $n$  in Equation 20.13) multiplies  $\Delta G_{\text{f}}^{\circ}$  by that number.
- Reversing a reaction changes the sign of  $\Delta G_{\text{f}}^{\circ}$ .

Many  $\Delta G_{\text{f}}^{\circ}$  values appear along with those for  $\Delta H_{\text{f}}^{\circ}$  and  $S^{\circ}$  in Appendix B.

## SAMPLE PROBLEM 20.8

Calculating  $\Delta G_{\text{rxn}}^{\circ}$  from  $\Delta G_{\text{f}}^{\circ}$  Values

**Problem** Use  $\Delta G_{\text{f}}^{\circ}$  values to calculate  $\Delta G_{\text{rxn}}^{\circ}$  for the reaction in Sample Problem 20.7:

**Plan** We apply Equation 20.13 to calculate  $\Delta G_{\text{rxn}}^{\circ}$ .

**Solution** Applying Equation 20.13 with values from Appendix B:

$$\begin{aligned}\Delta G_{\text{rxn}}^{\circ} &= \sum m\Delta G_{\text{f}}^{\circ}(\text{products}) - \sum n\Delta G_{\text{f}}^{\circ}(\text{reactants}) \\ &= [(3 \text{ mol KClO}_4)(\Delta G_{\text{f}}^{\circ} \text{ of KClO}_4) + (1 \text{ mol KCl})(\Delta G_{\text{f}}^{\circ} \text{ of KCl})] \\ &\quad - [(4 \text{ mol KClO}_3)(\Delta G_{\text{f}}^{\circ} \text{ of KClO}_3)] \\ &= [(3 \text{ mol})(-303.2 \text{ kJ/mol}) + (1 \text{ mol})(-409.2 \text{ kJ/mol})] \\ &\quad - [(4 \text{ mol})(-296.3 \text{ kJ/mol})] \\ &= \mathbf{-134 \text{ kJ}}\end{aligned}$$

**Check** Rounding to check the math:

$$\begin{aligned}\Delta G_{\text{rxn}}^{\circ} &\approx [3(-300 \text{ kJ}) + 1(-400 \text{ kJ})] - [4(-300 \text{ kJ})] \\ &= -1300 \text{ kJ} + 1200 \text{ kJ} = -100 \text{ kJ}\end{aligned}$$

**Comment** The slight discrepancy between this answer and the one obtained in Sample Problem 20.7 is due to rounding. As you can see, when  $\Delta G_{\text{f}}^{\circ}$  values are available, this method is simpler arithmetically than the approach in Sample Problem 20.7.

## FOLLOW-UP PROBLEMS

**20.8A** Use  $\Delta G_{\text{f}}^{\circ}$  values to calculate  $\Delta G_{\text{rxn}}^{\circ}$  at 298 K:

**20.8B** Use  $\Delta G_{\text{f}}^{\circ}$  values to calculate  $\Delta G_{\text{rxn}}^{\circ}$  at 25°C:

**SOME SIMILAR PROBLEMS** 20.51, 20.52, 20.55(b), and 20.56(b)

## The Free Energy Change and the Work a System Can Do

Thermodynamics developed after the invention of the steam engine, a major advance that spawned a new generation of machines. Thus, some of the field's key ideas applied the relationships between the free energy change and the work a system can do:

- $\Delta G$  is the *maximum useful work* that can be done *by* a system during a *spontaneous* process at constant  $T$  and  $P$ :

$$\Delta G = w_{\text{max}} \quad (20.14)$$

- $\Delta G$  is the *minimum work* that must be done *to* a system to make a *nonspontaneous* process occur at constant  $T$  and  $P$ .

The free energy change is the maximum work the system can *possibly* do. But the work it *actually* does is always less and depends on how the free energy is released. Let's consider the work done by two common systems—a car engine and a battery.

1. “Useful” work done by a car engine. When gasoline (represented by octane,  $\text{C}_8\text{H}_{18}$ ) is burned in a car engine,

a large amount of energy is released as heat ( $\Delta H_{\text{sys}} < 0$ ), and because the number of moles of gas increases, the entropy of the system increases ( $\Delta S_{\text{sys}} > 0$ ). Therefore, the reaction is spontaneous ( $\Delta G_{\text{sys}} < 0$ ). The free energy released turns the wheels, moves the belts, plays the radio, and so on—all examples of “useful” work. However, the *maximum* work is done by any spontaneous process *only if the free energy is released reversibly*, that is, *in an infinite number of steps*. Of course, in any *real* process, work is performed in a *finite* number of steps, that is, *irreversibly*, so the

*maximum work is never done.* Any free energy not used for work is lost to the surroundings as heat. For a car engine, much of the free energy released just warms the engine and the outside air, which increases the freedom of motion of the particles in the universe, in accord with the second law.

2. “Useful” work done by a battery. As you’ll see in Chapter 21, a battery is essentially a packaged spontaneous redox reaction that releases free energy in the form of an electric current to the surroundings (flashlight, computer, motor, etc.). If we connect the battery terminals to each other through a short piece of wire, the free energy change is released all at once but does no work—it just heats the wire and battery. If we connect the terminals to a motor, a significant portion of the free energy runs the motor, but some is still converted to heat. If we connect the battery to a more “efficient” device, one that discharges the free energy still more slowly, more of the energy does work and less is converted to heat. However, as with all systems, only when the battery discharges infinitely slowly can it do the maximum work.

*Efficiency* can be defined as the percentage of work output relative to the energy input. The range of efficiencies among common devices is very large: an incandescent bulb converts <7% of incoming electricity to light, with the rest given off as heat. At the other extreme, an electrical generator converts 95% of the incoming mechanical energy to electricity. Here are the efficiencies of some other devices: home oil furnace, 65%; hand-tool motor, 63%; liquid fuel rocket, 50%; car engine, <30%; compact fluorescent bulb, 18%; solar cell, ~15%. Therefore, all engineers must face the fact that *no real process uses all the available free energy to do work because some is always “wasted” as heat.*

Let’s summarize the relation between the free energy change of a reaction and the work it can do:

- A spontaneous reaction ( $\Delta G_{\text{sys}} < 0$ ) will do work on the surroundings ( $-w$ ). For any real machine, the actual work done is *always less than the maximum* because some of the  $\Delta G$  is released as heat.
- A nonspontaneous reaction ( $\Delta G_{\text{sys}} > 0$ ) will occur only if the surroundings do work on the system ( $+w$ ). For any real machine, the actual work done on the system is *always more than the minimum* because some of the added free energy is wasted as heat.
- A reaction at equilibrium ( $\Delta G_{\text{sys}} = 0$ ) can no longer do any work.

## The Effect of Temperature on Reaction Spontaneity

In most cases, the enthalpy contribution ( $\Delta H$ ) to the free energy change ( $\Delta G$ ) is much *larger* than the entropy contribution ( $T\Delta S$ ). In fact, the reason most exothermic reactions are spontaneous is that the large negative  $\Delta H$  makes  $\Delta G$  negative. However, the *temperature of a reaction influences the magnitude of the  $T\Delta S$  term*, so, for many reactions, the overall spontaneity depends on the temperature. From the signs of  $\Delta H$  and  $\Delta S$ , we can predict how the temperature affects the sign of  $\Delta G$ . (The values we’ll use below for the thermodynamic variables are standard-state values from Appendix B, but we show them without the degree sign to emphasize that the relationships among  $\Delta G$ ,  $\Delta H$ , and  $\Delta S$  are valid at any conditions. Also, we assume that  $\Delta H$  and  $\Delta S$  change little with temperature, which is true as long as no phase change occurs.)

Let’s examine the four combinations of positive and negative  $\Delta H$  and  $\Delta S$ —two that are independent of temperature and two that are dependent on temperature:

- *Temperature-independent cases.* When  $\Delta H$  and  $\Delta S$  have *opposite* signs, the reaction occurs spontaneously either at all temperatures or at none (nonspontaneous).
  1. *Reaction is spontaneous at all temperatures:* an exothermic reaction that has an increase in entropy has  $\Delta H < 0$ ,  $\Delta S > 0$ . Since  $\Delta S$  is positive,  $-T\Delta S$  is negative; thus, both contributions favor a negative  $\Delta G$ . Most combustion reactions are in this category. The decomposition of hydrogen peroxide, a common disinfectant, is also spontaneous at all temperatures:

2. *Reaction is nonspontaneous at all temperatures:* an endothermic reaction with a decrease in entropy has  $\Delta H > 0$ ,  $\Delta S < 0$ . Both contributions oppose spontaneity:  $\Delta H$  is positive and  $\Delta S$  is negative, so  $-T\Delta S$  is positive; thus,  $\Delta G$  is always positive. The formation of ozone from oxygen requires a continual energy input, so it is not spontaneous at any temperature:

- *Temperature-dependent cases.* When  $\Delta H$  and  $\Delta S$  have the *same* sign, the relative magnitudes of  $-T\Delta S$  and  $\Delta H$  determine the sign of  $\Delta G$ . In these cases, the *direction* of the change in  $T$  is crucial.

3. *Reaction becomes spontaneous as temperature increases:* an endothermic reaction with an increase in entropy has  $\Delta H > 0$  and  $\Delta S > 0$ . With a positive  $\Delta H$ , the reaction will occur spontaneously only when  $-T\Delta S$  becomes large enough to make  $\Delta G$  negative, which will happen as the temperature rises. For example,

The oxidation of  $\text{N}_2\text{O}$  occurs spontaneously at any  $T > 994 \text{ K}$ .

4. *Reaction becomes spontaneous as temperature decreases:* an exothermic reaction with a decrease in entropy has  $\Delta H < 0$  and  $\Delta S < 0$ . Here,  $\Delta H$  favors spontaneity, but  $\Delta S$  does not ( $-T\Delta S > 0$ ). The reaction will occur spontaneously only when  $-T\Delta S$  becomes smaller than  $\Delta H$ , and this happens as the temperature drops. For example,

The production of iron(III) oxide occurs spontaneously at any  $T < 3005 \text{ K}$ .

Table 20.2 summarizes these four possible combinations of  $\Delta H$  and  $\Delta S$ , and Sample Problem 20.9 applies them.

### Student Hot Spot

Student data indicate that you may struggle with understanding how temperature affects spontaneity. Access the Smartbook to view additional Learning Resources on this topic.

Table 20.2

Reaction Spontaneity and the Signs of  $\Delta H$ ,  $\Delta S$ , and  $\Delta G$

$\Delta H$	$\Delta S$	$-T\Delta S$	$\Delta G$	Description
–	+	–	–	Spontaneous at all $T$
+	–	+	+	Nonspontaneous at all $T$
+	+	–	+ or –	Spontaneous at higher $T$ ; nonspontaneous at lower $T$
–	–	+	+ or –	Spontaneous at lower $T$ ; nonspontaneous at higher $T$

### SAMPLE PROBLEM 20.9

### Using Molecular Scenes to Determine the Signs of $\Delta H$ , $\Delta S$ , and $\Delta G$

**Problem** The scenes below represent a familiar phase change for water (*blue spheres*):

- (a) What are the signs of  $\Delta H$  and  $\Delta S$  for this process? Explain.  
 (b) Is the process spontaneous at all  $T$ , no  $T$ , low  $T$ , or high  $T$ ? Explain.

**Plan** (a) From the scenes, we determine any change in amount of gas and/or any change in the freedom of motion of the particles, which will indicate the sign of  $\Delta S$ . Also, since the scenes represent a physical change, freedom of particle motion indicates whether heat is absorbed or released, and thus tells us the sign of  $\Delta H$ . (b) The question refers to the sign of  $\Delta G$  (+ or -) at the different temperature possibilities, so we apply Equation 20.11 and refer to the previous text discussion and Table 20.2.

**Solution** (a) The scenes represent the condensation of water vapor, so the amount of gas decreases dramatically, and the separated molecules give up energy as they come closer together. Therefore,  $\Delta S < 0$  and  $\Delta H < 0$ .

(b) With  $\Delta S$  negative, the  $-T\Delta S$  term is positive. In order for  $\Delta G < 0$ , the magnitude of  $T$  must be small. Therefore, the process is spontaneous at low  $T$ .

**Check** The answer in part (b) seems reasonable based on our analysis in part (a). The answer makes sense because we know from everyday experience that water condenses spontaneously, and it does so at low temperatures.

### FOLLOW-UP PROBLEMS

**20.9A** The scenes below represent the reaction of  $X_2Y_2$  to yield  $X_2$  (red) and  $Y_2$  (blue):

(a) What is the sign of  $\Delta S$  for the reaction?

(b) If the reaction is spontaneous only above  $325^\circ\text{C}$ , what is the sign of  $\Delta H$ ? Explain.

**20.9B** The scenes below represent the reaction of  $AB$  to yield  $A$  (gray) and  $B_2$  (red):

(a) What are the signs of  $\Delta S$  and  $\Delta H$  for the reaction?

(b) Is  $\Delta G < 0$  at higher  $T$ , lower  $T$ , all  $T$ , or no  $T$ ? Explain.

**SOME SIMILAR PROBLEMS** 20.47 and 20.48

As you saw in Sample Problem 20.7, one way to calculate  $\Delta G$  is from enthalpy and entropy changes. As long as phase changes don't occur,  $\Delta H$  and  $\Delta S$  usually change little with temperature, so we use their values at 298 K in the following sample problem 20.10 to examine the effect of  $T$  on  $\Delta G$  and, thus, on reaction spontaneity.

### SAMPLE PROBLEM 20.10

### Determining the Effect of Temperature on $\Delta G$

**Problem** A key step in the production of sulfuric acid is the oxidation of  $\text{SO}_2(g)$  to  $\text{SO}_3(g)$ :

At 298 K,  $\Delta G = -141.6$  kJ;  $\Delta H = -198.4$  kJ; and  $\Delta S = -187.9$  J/K.

(a) Use the given data to decide if this reaction is spontaneous at  $25^\circ\text{C}$ , and predict how  $\Delta G$  will change with increasing  $T$ .

(b) Assuming that  $\Delta H$  and  $\Delta S$  are constant with  $T$  (no phase change occurs), is the reaction spontaneous at  $900.^\circ\text{C}$ ?

**Plan** (a) We note the sign of  $\Delta G$  to see if the reaction is spontaneous and the signs of  $\Delta H$  and  $\Delta S$  to see the effect of  $T$ . (b) We use Equation 20.11 to calculate  $\Delta G$  from the given  $\Delta H$  and  $\Delta S$  at the higher  $T$  (in K).

**Solution** (a)  $\Delta G < 0$ , so the reaction is spontaneous at 298 K:  $\text{SO}_2$  and  $\text{O}_2$  will form  $\text{SO}_3$  spontaneously. With  $\Delta S < 0$ , the term  $-T\Delta S > 0$ , and this term will become more positive at higher  $T$ . Therefore,  $\Delta G$  will become less negative, and the reaction less spontaneous, with increasing  $T$ .

(b) Calculating  $\Delta G$  at  $900.^\circ\text{C}$  ( $T = 273 + 900. = 1173 \text{ K}$ ):

$$\Delta G = \Delta H - T\Delta S = -198.4 \text{ kJ} - [(1173 \text{ K})(-187.9 \text{ J/K})(1 \text{ kJ}/1000 \text{ J})] = 22.0 \text{ kJ}$$

Since  $\Delta G > 0$ , the reaction is nonspontaneous at the higher  $T$ .

**Check** The answer in part (b) seems reasonable based on our prediction in part (a). The arithmetic seems correct, with considerable rounding:

$$\Delta G \approx -200 \text{ kJ} - [(1200 \text{ K})(-200 \text{ J/K})(1 \text{ kJ}/1000 \text{ J})] = +40 \text{ kJ}$$

### FOLLOW-UP PROBLEMS

**20.10A** For the following reaction at 298 K,  $\Delta S = -308.2 \text{ J/K}$  and  $\Delta H = -192.7 \text{ kJ}$ :

(a) Is the reaction spontaneous at 298 K?

(b) Would the reaction become more or less spontaneous at higher  $T$ ?

(c) Assuming that  $\Delta S$  and  $\Delta H$  don't change with  $T$ , find  $\Delta G$  at  $500.^\circ\text{C}$ .

**20.10B** A reaction is nonspontaneous at room temperature but *is* spontaneous at  $-40^\circ\text{C}$ . What can you say about the signs and relative magnitudes of  $\Delta H$ ,  $\Delta S$ , and  $-T\Delta S$ ?

**SOME SIMILAR PROBLEMS** 20.57(b) and 20.58(b)

**The Temperature at Which a Reaction Becomes Spontaneous** As you've just seen, when the signs are the same for  $\Delta H$  and  $\Delta S$  of a reaction, it can be nonspontaneous at one temperature and spontaneous at another. The "crossover" temperature occurs when a positive  $\Delta G$  switches to a negative  $\Delta G$  because of the magnitude of the  $-T\Delta S$  term. We find this temperature by setting  $\Delta G$  equal to zero and solving for  $T$ :

$$\Delta G = \Delta H - T\Delta S = 0$$

Therefore,

$$\Delta H = T\Delta S \quad \text{and} \quad T = \frac{\Delta H}{\Delta S} \quad (20.15)$$

Consider the reaction of copper(I) oxide with carbon. It does *not* occur at very low temperatures but does at higher temperatures and is used to extract copper from one of its ores:

We predict that this reaction has a positive  $\Delta S$  because the number of moles of gas increases; in fact,  $\Delta S = 165 \text{ J/K}$ . Furthermore, because the reaction is *nonspontaneous* at lower temperatures, it must have a positive  $\Delta H$ ; the actual value is  $58.1 \text{ kJ}$ . As the  $-T\Delta S$  term becomes more negative with higher  $T$ , it eventually outweighs the positive  $\Delta H$  term, so  $\Delta G$  becomes negative and the reaction occurs spontaneously.

### SAMPLE PROBLEM 20.11

#### Finding the Temperature at Which a Reaction Becomes Spontaneous

**Problem** At  $25^\circ\text{C}$  (298 K), the reduction of copper(I) oxide to copper is nonspontaneous ( $\Delta G = 8.9 \text{ kJ}$ ). Calculate the temperature at which the reaction becomes spontaneous.

**Plan** As just discussed, we want the temperature at which  $\Delta G$  crosses over from a positive to a negative value. We set  $\Delta G$  equal to zero, and use Equation 20.15 to solve for  $T$ , using the values of  $\Delta H$  ( $58.1 \text{ kJ}$ ) and  $\Delta S$  ( $165 \text{ J/K}$ ) given in the text.

**Solution** From  $\Delta G = \Delta H - T\Delta S = 0$ , we have

$$T = \frac{\Delta H}{\Delta S} = \frac{58.1 \text{ kJ} \times \frac{1000 \text{ J}}{1 \text{ kJ}}}{165 \text{ J/K}} = 352 \text{ K}$$

Thus, at any temperature above 352 K (79°C), which is a moderate temperature for extracting a metal from its ore,  $\Delta G < 0$ , so the reaction becomes spontaneous.

**Check** Rounding to quickly check the math gives

$$T = \frac{60,000 \text{ J}}{150 \text{ J/K}} = 400 \text{ K}$$

which is close to the answer.

### FOLLOW-UP PROBLEMS

**20.11A** Find the temperature (in °C) above which the reaction in Follow-up Problem 20.10A is no longer spontaneous.

**20.11B** Use Appendix B values to find the temperature at which the following reaction becomes spontaneous (assume  $\Delta H$  and  $\Delta S$  are constant with  $T$ ):

**SOME SIMILAR PROBLEMS** 20.59(d), 20.60(d), and 20.61(c)

**Figure 20.14** The effect of temperature on reaction spontaneity. At low  $T$ ,  $\Delta G > 0$  because  $\Delta H$  dominates for the reduction of copper(I) oxide to copper. At 352 K,  $\Delta H = T\Delta S$ , so  $\Delta G = 0$ . At any higher  $T$ ,  $\Delta G < 0$  because  $-T\Delta S$  dominates.

Figure 20.14 shows that the line for  $T\Delta S$  rises steadily (and thus the  $-T\Delta S$  term becomes more negative) with increasing temperature. This line crosses the relatively constant  $\Delta H$  line at 352 K for the reduction of copper(I) oxide to copper, as we found in Sample Problem 20.11. At any higher temperature, the  $-T\Delta S$  term is greater than the  $\Delta H$  term, so  $\Delta G$  is negative.

### Coupling of Reactions to Drive a Nonspontaneous Change

In a complex, multistep reaction, we often see a nonspontaneous step driven by a spontaneous step. In such a **coupling of reactions**, *one step supplies enough free energy for the other to occur*, just as burning gasoline supplies enough free energy to move a car.

Look again at the reduction of copper(I) oxide by carbon. In Sample Problem 20.11, we found that the *overall* reaction becomes spontaneous at any temperature above 352 K. Dividing the reaction into two steps, however, we find that even at a higher temperature, say 375 K, copper(I) oxide does not spontaneously decompose to its elements:

However, the oxidation of carbon to CO at 375 K is quite spontaneous:

Coupling these reactions means having the carbon in contact with the  $\text{Cu}_2\text{O}$ , which allows the reaction with the larger negative  $\Delta G$  to “drive” the one with the smaller positive  $\Delta G$ . Adding the reactions together and canceling the common substance ( $\frac{1}{2}\text{O}_2$ ) gives an overall reaction with a negative  $\Delta G$ :

Many biochemical reactions are also nonspontaneous, including key steps in the syntheses of proteins and nucleic acids, the formation of fatty acids, the maintenance of ion balance, and the breakdown of nutrients. Driving a nonspontaneous step by coupling it to a spontaneous one is a life-sustaining strategy common to all organisms, as you’ll see in the upcoming Chemical Connections essay.

### Summary of Section 20.3

- › The sign of the free energy change,  $\Delta G = \Delta H - T\Delta S$ , is directly related to reaction spontaneity: a negative  $\Delta G$  corresponds to a positive  $\Delta S_{\text{univ}}$ .
- › We use the standard free energy of formation ( $\Delta G_f^\circ$ ) to calculate  $\Delta G_{\text{rxn}}^\circ$  at 298 K.
- › The maximum work a system can do is never obtained from a real (irreversible) process because some free energy is always converted to heat.
- › The magnitude of  $T$  influences the spontaneity of a temperature-dependent reaction (same signs of  $\Delta H$  and  $\Delta S$ ) by affecting the size of  $T\Delta S$ . For such a reaction, the  $T$  at which the reaction becomes spontaneous can be found by setting  $\Delta G = 0$ .
- › A nonspontaneous reaction ( $\Delta G > 0$ ) can be coupled to a more spontaneous one ( $\Delta G \ll 0$ ) to make it occur. For example, in organisms, the hydrolysis of ATP drives many reactions that have a positive  $\Delta G$ .

Despite their incredible diversity, virtually all organisms use the same amino acids to make their proteins, the same nucleotides to make their nucleic acids, and the same carbohydrate (glucose) to provide energy.

In addition, *all organisms use the same spontaneous reaction to drive a variety of nonspontaneous ones.* This reaction is the hydrolysis of **adenosine triphosphate (ATP)** to adenosine diphosphate (ADP):\*

In the metabolic breakdown of glucose, for example, the first step, addition of  $\text{HPO}_4^{2-}$  to glucose, is nonspontaneous:

Coupling this nonspontaneous reaction to ATP hydrolysis makes the overall process spontaneous. If we add the two reactions,  $\text{HPO}_4^{2-}$ ,  $\text{H}^+$ , and  $\text{H}_2\text{O}$  cancel:

Coupling cannot occur if reactions are physically separated, so these reactions take place on an enzyme (Section 16.7) that simultaneously binds glucose and ATP, and the phosphate group of ATP that will be transferred lies next to the  $-\text{OH}$  group of glucose that will bind it (Figure B20.1).

The ADP produced in energy-releasing reactions combines with phosphate to regenerate ATP in energy-absorbing reactions

\*In biochemical systems, the standard-state concentration of  $\text{H}^+$  is  $10^{-7} \text{ M}$ , not the usual  $1 \text{ M}$ , and the standard free energy change is represented by the symbol  $\Delta G^{\circ'}$ .

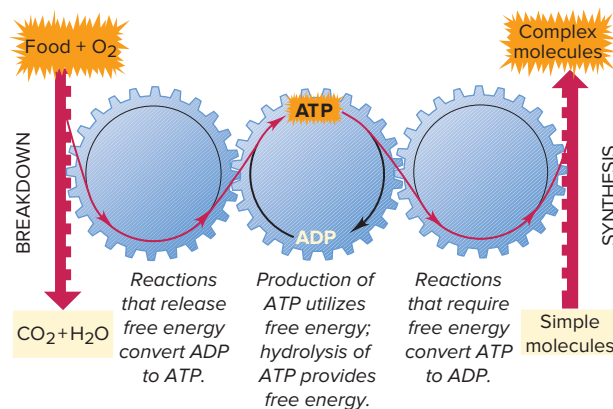

Figure B20.2 The cycling of metabolic free energy.

catalyzed by other enzymes. Thus, there is a continuous cycling of ATP to ADP and back to ATP again to supply energy to the cells (Figure B20.2).

Why is ATP a “high-energy” molecule? By examining the phosphate portions of ATP, ADP, and  $\text{HPO}_4^{2-}$ , we can see two basic chemical reasons why ATP hydrolysis supplies so much free energy (Figure B20.3):

1. *Charge repulsion.* At physiological pH ( $\sim 7$ ), the triphosphate group of ATP has four negative charges close together. This *high charge repulsion* is reduced in ADP (Figure B20.3A).
2. *Electron delocalization.* Once  $\text{HPO}_4^{2-}$  is free, there is extensive delocalization and resonance stabilization of the  $\pi$  electrons (Figure B20.3B).

Figure B20.1 The coupling of a nonspontaneous reaction to the hydrolysis of ATP. Glucose lies next to ATP (shown as  $\text{ADP}-\text{O}-\text{PO}_3\text{H}$ ) in the enzyme's active site. ADP (shown as  $\text{ADP}-\text{OH}$ ) and glucose phosphate are released.

(continued)

**Figure B20.3** ATP is a high-energy molecule.

Thus, greater charge repulsion and less electron delocalization make ATP higher in energy (less stable) than the sum of the energies of ADP and  $HPO_4^{2-}$ . When ATP is hydrolyzed, some of this additional energy is released and harnessed by the organism to drive metabolic reactions that could not otherwise take place.

## Problems

**B20.1** The oxidation of 1 mol of glucose supplies enough metabolic energy to form 36 mol of ATP. Oxidation of 1 mol of a typical dietary fat like tristearin ( $C_{57}H_{116}O_6$ ) yields enough energy to form 458 mol of ATP. How many molecules of ATP can form per gram of (a) glucose; (b) tristearin?

**B20.2** Nonspontaneous processes like muscle contraction, protein synthesis, and nerve conduction are coupled to the spontaneous hydrolysis of ATP to ADP. ATP is then regenerated by coupling its synthesis to energy-yielding reactions such as

Creatine phosphate  $\longrightarrow$  creatine + phosphate

$$\Delta G^{\circ'} = -43.1 \text{ kJ/mol}$$

Find  $\Delta G^{\circ'}$  for the overall reaction that regenerates ATP from ADP and  $HPO_4^{2-}$  by coupling the synthesis with the breakdown of creatine phosphate.

## 20.4 FREE ENERGY, EQUILIBRIUM, AND REACTION DIRECTION

*A chemical reaction proceeding toward equilibrium is a spontaneous change.* But why is there a drive to attain equilibrium? And what determines the value of the equilibrium constant?

As you know from earlier discussions, the sign of  $\Delta G$  is not the only way to predict reaction direction. In Section 17.4, we did so by comparing the values of the reaction quotient ( $Q$ ) and the equilibrium constant ( $K$ ). Recall that a reaction is proceeding to the right when  $Q < K$ , and to the left when  $Q > K$ ; if  $Q = K$ , the reaction is at equilibrium.

It is easier to see the relation between these two ways to predict reaction spontaneity—the sign of  $\Delta G$  and the magnitude of  $Q$  versus the magnitude of  $K$ —when we compare the sign of the natural logarithm of the ratio of  $Q$  to  $K$  ( $\ln Q/K$ ) with the sign of  $\Delta G$  (refer to Appendix A if necessary), as shown in Table 20.3.

**Table 20.3**  $Q$ ,  $K$ ,  $\Delta G$ , and Reaction Spontaneity

$Q$	$Q/K$	$\ln Q/K$	$\Delta G$	Direction of reaction
$Q < K$	$Q/K < 1$	$\ln Q/K < 0$	$\Delta G < 0$	Spontaneously to the right
$Q > K$	$Q/K > 1$	$\ln Q/K > 0$	$\Delta G > 0$	Spontaneously to the left
$Q = K$	$Q/K = 1$	$\ln Q/K = 0$	$\Delta G = 0$	At equilibrium

Note that the signs of  $\Delta G$  and of  $\ln Q/K$  are the same for a given direction; in fact,  $\Delta G$  equals  $\ln Q/K$  multiplied by the proportionality constant  $RT$ :

$$\Delta G = RT \ln \frac{Q}{K} = RT \ln Q - RT \ln K \quad (20.16)$$

$Q$  represents the concentrations (or pressures) of a system's components at any time during the reaction, and  $K$  represents these quantities at equilibrium. Therefore,

Equation 20.16 says that  $\Delta G$  is a measure of how different the concentrations at any time,  $Q$ , are from the concentrations at equilibrium,  $K$ :

- If  $Q$  and  $K$  are very different, the reaction releases (or absorbs) a *lot* of free energy.
- If  $Q$  and  $K$  are nearly the same, the reaction releases (or absorbs) *relatively little* free energy.

**The Standard Free Energy Change and the Equilibrium Constant** When we choose standard-state values for  $Q$  (1 atm for gases, 1  $M$  for solutions, etc.),  $\Delta G$  in Equation 20.16 becomes, by definition,  $\Delta G^\circ$  and  $Q$  equals 1:

$$\Delta G^\circ = RT \ln 1 - RT \ln K$$

Since  $\ln 1 = 0$ , the term “ $RT \ln Q$ ” drops out, which allows us to find the standard free energy change of a reaction ( $\Delta G_{\text{rxn}}^\circ$ ) from its equilibrium constant, or vice versa:

$$\Delta G^\circ = -RT \ln K \quad (20.17)$$

The following sample problem applies this central relationship.

### Student Hot Spot

Student data indicate that you may struggle with the relationship between Gibbs free energy and equilibrium. Access the Smartbook to view additional Learning Resources on this topic.

#### SAMPLE PROBLEM 20.12

#### Exploring the Relationship Between $\Delta G^\circ$ and $K$

**Problem** (a) Use Appendix B to find  $K$  at 298 K for the following reaction:

(b) Use the equilibrium constant to calculate  $\Delta G^\circ$  at 298 K for the following reaction:

**Plan** (a) We use  $\Delta G_f^\circ$  values from Appendix B with Equation 20.13 to find  $\Delta G^\circ$ , and then we use Equation 20.17 to solve for  $K$ . (b) In this calculation, we do the reverse of the second calculation in part (a): we are given  $K = 3.89 \times 10^{-34}$ , so we use Equation 20.17 to solve for  $\Delta G^\circ$ .

**Solution** (a) Solving for  $\Delta G^\circ$  using  $\Delta G_f^\circ$  values from Appendix B and Equation 20.13 (see Sample Problem 20.8):

$$\begin{aligned} \Delta G^\circ &= [(1 \text{ mol NO}_2)(\Delta G_f^\circ \text{ of NO}_2)] - [(1 \text{ mol NO})(\Delta G_f^\circ \text{ of NO}) \\ &\quad + (\frac{1}{2} \text{ mol of O}_2)(\Delta G_f^\circ \text{ of O}_2)] \\ &= [(1 \text{ mol})(51 \text{ kJ/mol})] - [(1 \text{ mol})(86.60 \text{ kJ/mol}) + (\frac{1}{2} \text{ mol})(0 \text{ kJ/mol})] \\ &= -36 \text{ kJ} \end{aligned}$$

Solving for  $K$  using Equation 20.17:

$$\begin{aligned} \Delta G^\circ &= -RT \ln K \\ \text{so } \ln K &= -\frac{\Delta G^\circ}{RT} = -\frac{(-36 \text{ kJ})(1000 \text{ J/1 kJ})}{(8.314 \text{ J/mol}\cdot\text{K})(298 \text{ K})} = 14.53 \\ K &= e^{14.53} = 2.0 \times 10^6 \end{aligned}$$

(b) Solving for  $\Delta G^\circ$  using Equation 20.17:

$$\begin{aligned} K &= 3.89 \times 10^{-34} \quad \text{so } \ln K = -76.9 \\ \Delta G^\circ &= -RT \ln K = -(8.314 \text{ J/mol}\cdot\text{K})(298 \text{ K})(-76.9) \\ &= 1.91 \times 10^5 \text{ J} = 191 \text{ kJ} \end{aligned}$$

**Check** (a) A negative free energy change is consistent with a large  $K$  value ( $K > 1$ ), as both are an indication that a reaction is proceeding to the right. Rounding to confirm the value of  $\Delta G^\circ$  gives  $50 \text{ kJ} - 90 \text{ kJ} = -40 \text{ kJ}$ , close to the calculated value. (b) A very small value of  $K$  ( $K < 1$ ) is consistent with a highly positive  $\Delta G^\circ$ , as both indicate that a reaction is proceeding to the left. Looking up  $\Delta G_f^\circ$  values to check the value of  $\Delta G^\circ$  gives  $(0 \text{ kJ} + 0 \text{ kJ}) - [2(-95.30 \text{ kJ})] = -190.6 \text{ kJ}$ .

#### FOLLOW-UP PROBLEMS

**20.12A** Use Appendix B to find  $K$  at 298 K for the following reaction:

**20.12B** Use the given value of  $K$  to calculate  $\Delta G^\circ$  at 298 K for the following reaction:

**SOME SIMILAR PROBLEMS** 20.67–20.70

Table 20.4

The Relationship Between  $\Delta G^\circ$  and  $K$  at 298 K

$\Delta G^\circ$ (kJ)	$K$	Significance
200	$9 \times 10^{-36}$	Essentially no forward reaction; reverse reaction goes to completion.
100	$3 \times 10^{-18}$	
50	$2 \times 10^{-9}$	
10	$2 \times 10^{-2}$	
1	$7 \times 10^{-1}$	Forward and reverse reactions proceed to same extent.
0	1	
-1	1.5	
-10	$5 \times 10^1$	Forward reaction goes to completion; essentially no reverse reaction.
-50	$6 \times 10^8$	
-100	$3 \times 10^{17}$	
-200	$1 \times 10^{35}$	

Table 20.4 shows that, due to their logarithmic relationship, a small change in  $\Delta G^\circ$  causes a large change in  $K$ . Note just these two examples:

- As  $\Delta G^\circ$  becomes more positive,  $K$  becomes smaller: if  $\Delta G^\circ = +10$  kJ,  $K$  is 0.02, so the product terms are  $\frac{1}{50}$  the size of the reactant terms (see Figure 17.2A).
- As  $\Delta G^\circ$  becomes more negative,  $K$  becomes larger: if  $\Delta G^\circ = -10$  kJ,  $K$  is 50, so the product terms are 50 times larger than the reactant terms (see Figure 17.2B).

**Finding the Free Energy Change Under Any Conditions** In reality, reactions rarely begin with all components in their standard states. By substituting the relationship between  $\Delta G^\circ$  and  $K$  (Equation 20.17) into the expression for  $\Delta G$  (Equation 20.16), we obtain a relationship that applies to *any starting concentrations*:

$$\Delta G = \Delta G^\circ + RT \ln Q \quad (20.18)$$

Note that, by definition, when the components are in their standard states (1 M, 1 atm, etc.),  $\Delta G = \Delta G^\circ$ :

$$\begin{aligned} \Delta G &= \Delta G^\circ + RT \ln Q = \Delta G^\circ + RT \ln 1 \\ \Delta G &= \Delta G^\circ \end{aligned}$$

Sample Problem 20.13 uses molecular scenes to explore these ideas, and Sample Problem 20.14 applies them to an important industrial reaction.

## SAMPLE PROBLEM 20.13

Using Molecular Scenes to Find  $\Delta G$  for a Reaction at Nonstandard Conditions

**Problem** These molecular scenes represent three mixtures in which  $A_2$  (black) and  $B_2$  (green) are forming AB. Each molecule represents 0.10 atm. The equation is

- If mixture 1 is at equilibrium, calculate  $K$ .
- Which mixture has the most negative  $\Delta G$ , and which has the most positive?

**Plan** (a) Mixture 1 is at equilibrium, so we first write the expression for  $Q$  and then find the partial pressure of each substance from the numbers of molecules and calculate  $K$ . (b) To find  $\Delta G$ , we apply Equation 20.18. We are given  $\Delta G^\circ$  ( $-3.4$  kJ/mol) and know  $R$  ( $8.314$  J/mol·K), but we still need to find  $T$ . We calculate  $T$  from Equation 20.17 using  $K$  from part (a), and substitute the partial pressure of each substance (by counting particles) to get  $Q$ .

**Solution** (a) Writing the expression for  $Q$  and calculating  $K$ :

(b) Calculating  $T$  from Equation 20.17 for use in Equation 20.18:

$$\begin{aligned} \Delta G^\circ &= -RT \ln K \\ T &= \frac{\Delta G^\circ}{-R \ln K} = \frac{-3.4 \text{ kJ} \left( \frac{1000 \text{ J}}{1 \text{ kJ}} \right)}{-8.314 \text{ J/mol}\cdot\text{K} \times \ln 4.0} = 295 \text{ K} \end{aligned}$$

Calculating  $\Delta G$  from Equation 20.18 for each reaction mixture:

Mixture 1:

$$\begin{aligned} \Delta G &= \Delta G^\circ + RT \ln Q = -3.4 \text{ kJ} + RT \ln 4.0 \\ &= -3.4 \text{ kJ/mol} \left( \frac{1000 \text{ J}}{1 \text{ kJ}} \right) + \left( \frac{8.314 \text{ J}}{\text{mol}\cdot\text{K}} \right) (295 \text{ K}) \ln 4.0 \\ &= -3400 \text{ J/mol} + 3400 \text{ J/mol} = 0.0 \text{ J} \end{aligned}$$

Mixture 2:

$$\begin{aligned} \Delta G &= -3.4 \text{ kJ/mol} + RT \ln \frac{(0.20)^2}{(0.30)(0.30)} \\ &= -3.4 \text{ kJ/mol} \left( \frac{1000 \text{ J}}{1 \text{ kJ}} \right) + \left( \frac{8.314 \text{ J}}{\text{mol}\cdot\text{K}} \right) (295 \text{ K}) \ln 0.44 \\ &= -5.4 \times 10^3 \text{ J/mol} \end{aligned}$$

Mixture 3:

$$\begin{aligned} \Delta G &= -3.4 \text{ kJ/mol} + RT \ln \frac{(0.60)^2}{(0.10)(0.10)} \\ &= -3.4 \text{ kJ/mol} \left( \frac{1000 \text{ J}}{1 \text{ kJ}} \right) + \left( \frac{8.314 \text{ J}}{\text{mol}\cdot\text{K}} \right) (295 \text{ K}) \ln 36 \\ &= 5.4 \times 10^3 \text{ J/mol} \end{aligned}$$

Mixture 2 has the most negative  $\Delta G$ , and mixture 3 has the most positive  $\Delta G$ .

**Check** In part (b), round to check the arithmetic; for example, for mixture 3,  $\Delta G \approx -3000 \text{ J/mol} + (8 \text{ J/mol}\cdot\text{K})(300 \text{ K})4 \approx 7000 \text{ J/mol}$ , which is in the ballpark.

**Comment 1.** By using the properties of logarithms, we did *not* have to calculate  $T$  and  $\Delta G$  in part (b). For mixture 2,  $Q < 1$ , so  $\ln Q$  is negative, which makes  $\Delta G$  more negative. Also, note that  $Q(0.44) < K(4.0)$ , which tells us that the reaction is proceeding to the right, so  $\Delta G < 0$ . For mixture 3,  $Q > 1$  (and is greater than it is for mixture 1), so  $\ln Q$  is positive, which makes  $\Delta G$  positive. Also,  $Q(36) > K(4.0)$ , which tells us that the reaction is proceeding to the left, so  $\Delta G > 0$ .

2. In part (b), the value of zero for  $\Delta G$  of the equilibrium mixture (mixture 1) makes sense, because a system at equilibrium has released all of its free energy.

3. Note especially that, by definition, when the components are in their standard states,  $\Delta G = \Delta G^\circ$ :

$$\begin{aligned} \Delta G &= \Delta G^\circ + RT \ln Q = -3.4 \text{ kJ/mol} + RT \ln \frac{(1.0)^2}{(1.0)(1.0)} \\ &= -3.4 \text{ kJ/mol} + RT \ln 1.0 = -3.4 \text{ kJ/mol} \end{aligned}$$

## FOLLOW-UP PROBLEMS

**20.13A** The scenes below depict three mixtures in which A (orange) and B (green) are forming  $AB_3$  in a reaction for which  $\Delta G^\circ = -4.6$  kJ/mol. Assume that each molecule represents 0.10 mol and the volume is 1.0 L.

(a) Write a balanced equation for the reaction. (b) If  $K = 8.0$ , which mixture is at equilibrium? (c) Rank the three mixtures from the highest (most positive)  $\Delta G$  to the lowest (most negative)  $\Delta G$ .

**20.13B** The scenes below depict mixtures in which  $X_2$  (tan) and  $Y_2$  (blue) are forming  $XY_2$ . Each molecule represents 0.10 mol, and the volume is 0.10 L. The equation is

(a) If  $K = 2.0$ , which mixture is at equilibrium? (b) Rank the three mixtures from the lowest (most negative)  $\Delta G$  to highest (most positive)  $\Delta G$ . (c) What is the sign of  $\Delta G$  for the change that occurs as each nonequilibrium mixture approaches equilibrium?

**SOME SIMILAR PROBLEMS** 20.81 and 20.82

## Student Hot Spot

Student data indicate that you may struggle with the calculation of  $\Delta G$  under nonstandard conditions. Access the Smartbook to view additional Learning Resources on this topic.

## SAMPLE PROBLEM 20.14

Calculating  $\Delta G$  at Nonstandard Conditions

**Problem** The oxidation of  $SO_2(g)$ ,  $2SO_2(g) + O_2(g) \rightarrow 2SO_3(g)$ , is the key reaction in the manufacture of sulfuric acid.

- (a) Calculate  $K$  at 298 K. ( $\Delta G_{298}^\circ = -141.6$  kJ/mol of reaction as written.)  
 (b) A container is filled with 0.500 atm of  $SO_2$ , 0.0100 atm of  $O_2$ , and 0.100 atm of  $SO_3$  and kept at 25°C. In which direction, if any, will the reaction proceed to reach equilibrium?  
 (c) Calculate  $\Delta G$  for the system in part (b).

**Plan** (a) We know  $\Delta G^\circ$ ,  $T$ , and  $R$ , so we can calculate  $K$  from Equation 20.17 [see Sample Problem 20.12(a)]. (b) To determine if a net reaction will occur, we find  $Q$  from the given partial pressures and compare it with  $K$  from part (a). (c) These are *not* standard-state pressures, so we find  $\Delta G$  at 298 K with Equation 20.18, using the values of  $\Delta G^\circ$  (given) and  $Q$  [from part (b)].

**Solution** (a) Calculating  $K$  at 298 K:

$$\Delta G^\circ = -RT \ln K \quad \text{so} \quad K = e^{-(\Delta G^\circ/RT)}$$

At 298 K, the exponent is

$$-(\Delta G^\circ/RT) = -\left(\frac{-141.6 \text{ kJ/mol} \times \frac{1000 \text{ J}}{1 \text{ kJ}}}{8.314 \text{ J/mol}\cdot\text{K} \times 298 \text{ K}}\right) = 57.2$$

so

$$K = e^{-(\Delta G^\circ/RT)} = e^{57.2} = 7 \times 10^{24}$$

(b) Calculating the value of  $Q$ :

$$Q = \frac{(P_{\text{SO}_3})^2}{(P_{\text{SO}_2})^2 \times P_{\text{O}_2}} = \frac{0.100^2}{0.500^2 \times 0.0100} = 4.00$$

Because  $Q < K$ , the denominator will decrease and the numerator will increase—more  $\text{SO}_3$  will form—until  $Q$  equals  $K$ . To reach equilibrium, the reaction will proceed to the right.

(c) Calculating  $\Delta G$ , the nonstandard free energy change, at 298 K:

$$\begin{aligned} \Delta G_{298} &= \Delta G^\circ + RT \ln Q \\ &= -141.6 \text{ kJ/mol} + \left( 8.314 \text{ J/mol}\cdot\text{K} \times \frac{1 \text{ kJ}}{1000 \text{ J}} \times 298 \text{ K} \times \ln 4.00 \right) \\ &= -138.2 \text{ kJ/mol} \end{aligned}$$

**Check** Note that in parts (a) and (c), we made the free energy units (kJ) consistent with the units in  $R$  (J). Applying the rules for significant figures in addition and subtraction, we retain one digit to the right of the decimal place in part (c).

**Comment** As with the synthesis of  $\text{NH}_3$  (Section 17.6), where the *yield* is high but the *rate* is low at a lower temperature, this process is carried out at higher temperature *with a catalyst* to attain a higher *rate*. We discuss the details of the industrial production of sulfuric acid in Chapter 22.

### FOLLOW-UP PROBLEMS

**20.14A** At 298 K,  $\Delta G^\circ = -33.5 \text{ kJ/mol}$  for the formation of chloroethane from ethylene and hydrogen chloride:

(a) Calculate  $K$  at 298 K.

(b) Calculate  $\Delta G$  at 298 K if  $[\text{C}_2\text{H}_5\text{Cl}] = 1.5 \text{ M}$ ,  $[\text{C}_2\text{H}_4] = 0.50 \text{ M}$ , and  $[\text{HCl}] = 1.0 \text{ M}$ .

**20.14B** At 298 K, hypobromous acid ( $\text{HBrO}$ ) dissociates in water with  $K_a = 2.3 \times 10^{-9}$ .

(a) Calculate  $\Delta G^\circ$  for the dissociation of  $\text{HBrO}$ .

(b) Calculate  $\Delta G$  if  $[\text{H}_3\text{O}^+] = 6.0 \times 10^{-4} \text{ M}$ ,  $[\text{BrO}^-] = 0.10 \text{ M}$ , and  $[\text{HBrO}] = 0.20 \text{ M}$ .

**SOME SIMILAR PROBLEMS** 20.79 and 20.80

**Another Look at the Meaning of Spontaneity** At this point, we introduce two terms related to *spontaneous* and *nonspontaneous*:

1. *Product-favored reaction.* For the general reaction

Therefore, the reaction proceeds largely from left to right (Figure 20.15A, *next page*). From pure A to equilibrium,  $Q < K$  and the curved *green* arrow in the figure indicates that the reaction is spontaneous ( $\Delta G < 0$ ). From equilibrium to pure B, the curved *red* arrow indicates that the reaction is nonspontaneous ( $\Delta G > 0$ ). Similarly, from pure B to equilibrium,  $Q > K$  and the reaction is also spontaneous ( $\Delta G < 0$ ), but not thereafter. In either case, *free energy decreases until the reaction reaches a minimum at the equilibrium mixture:  $Q = K$  and  $\Delta G = 0$* . For the overall reaction  $\text{A} \rightleftharpoons \text{B}$  (starting with all components in their standard states),  $G_B^\circ$  is smaller than  $G_A^\circ$ , so  $\Delta G^\circ$  is negative, which corresponds to  $K > 1$ . We call this a *product-favored* reaction because in its final state the system contains mostly product.

2. *Reactant-favored reaction.* For the general reaction

and this reaction proceeds slightly from left to right (Figure 20.15B). Here, too, whether we start with pure C or pure D, the reaction is spontaneous ( $\Delta G < 0$ ) until equilibrium. In this case, however, the equilibrium mixture contains mostly C (the reactant), so we say the reaction is *reactant favored*. Here,  $G_D^\circ$  is larger than  $G_C^\circ$ , so  $\Delta G^\circ$  is *positive*, which corresponds to  $K < 1$ .

Thus, “spontaneous” refers to that *portion* of a reaction in which the free energy decreases—from the starting mixture to the equilibrium mixture. A product-favored

**Figure 20.15** Free energy and the extent of reaction. Each reaction proceeds spontaneously (curved green arrows) from reactants (A or C) or products (B or D) to the equilibrium mixture, at which point  $\Delta G = 0$ . After that, the reaction is nonspontaneous (curved red arrows). **A**, For the product-favored reaction  $A \rightleftharpoons B$ ,  $G_A^\circ > G_B^\circ$ , so  $\Delta G^\circ < 0$  and  $K > 1$ . **B**, For the reactant-favored reaction  $C \rightleftharpoons D$ ,  $G_B^\circ > G_C^\circ$ , so  $\Delta G^\circ > 0$  and  $K < 1$ .

reaction goes predominantly, but *not* completely, toward product, and a reactant-favored reaction goes relatively little toward product (see Table 20.4).

### › Summary of Section 20.4

- › Two ways of predicting reaction spontaneity are from the sign of  $\Delta G$  or from the value of  $Q/K$ . These variables are related to each other by  $\Delta G = RT \ln Q/K$ . When  $Q = K$ ,  $Q/K = 1$  and  $\ln Q/K = 0$ . Thus, the system is at equilibrium and can release (or absorb) no more free energy.
- › When  $Q$  is determined with standard-state values, the free energy change is  $\Delta G^\circ$  and is related to the equilibrium constant:  $\Delta G^\circ = -RT \ln K$ .
- › Any nonequilibrium mixture of reactants and products moves spontaneously ( $\Delta G < 0$ ) toward the equilibrium mixture.
- › A product-favored reaction goes predominantly toward product and, thus, has  $K > 1$  and  $\Delta G^\circ < 0$ ; a reactant-favored reaction has  $K < 1$  and  $\Delta G^\circ > 0$ .

## CHAPTER REVIEW GUIDE

### Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

#### Understand These Concepts

1. How the tendency of a process to occur by itself is distinct from how long it takes to occur (Introduction)
2. The distinction between a spontaneous and a nonspontaneous change (§20.1)
3. Why the first law of thermodynamics and the sign of  $\Delta H^\circ$  cannot predict the direction of a spontaneous process (§20.1)
4. How the entropy ( $S$ ) of a system is defined by the number of microstates over which its energy is dispersed (§20.1)
5. How entropy is alternatively defined by the heat absorbed (or released) at constant  $T$  in a reversible process (§20.1)
6. The criterion for spontaneity according to the second law of thermodynamics: that a change increases  $S_{\text{univ}}$  (§20.1)
7. How absolute values of standard molar entropies ( $S^\circ$ ) can be obtained because the third law of thermodynamics provides a zero point (§20.1)
8. How temperature, physical state, dissolution, atomic size, and molecular complexity influence  $S^\circ$  values (§20.1)
9. How  $\Delta S_{\text{rxn}}^\circ$  is based on the difference between the summed  $S^\circ$  values for the reactants and those for products (§20.2)
10. How the surroundings add heat to or remove heat from the system and how  $\Delta S_{\text{surr}}$  influences overall  $\Delta S_{\text{rxn}}^\circ$  (§20.2)
11. The relationship between  $\Delta S_{\text{surr}}$  and  $\Delta H_{\text{sys}}$  (§20.2)
12. How reactions proceed spontaneously toward equilibrium ( $\Delta S_{\text{univ}} > 0$ ) but proceed no further at equilibrium ( $\Delta S_{\text{univ}} = 0$ ) (§20.2)
13. How the free energy change ( $\Delta G$ ) combines a system's entropy and enthalpy changes (§20.3)
14. How the expression for the free energy change is derived from the second law (§20.3)
15. The relationship between  $\Delta G$  and the maximum work a system can perform and why this quantity of work is never performed in a real process (§20.3)

- How temperature determines spontaneity for reactions in which  $\Delta S$  and  $\Delta H$  have the same sign (§20.3)
- Why the temperature at which a reaction becomes spontaneous occurs when  $\Delta G = 0$  (§20.3)
- How a spontaneous change can be coupled to a nonspontaneous change to make it occur (§20.3)
- How  $\Delta G$  is related to the ratio of  $Q$  to  $K$  (§20.4)
- The meaning of  $\Delta G^\circ$  and its relation to  $K$  (§20.4)
- The relation of  $\Delta G$  to  $\Delta G^\circ$  and  $Q$  (§20.4)
- Why  $G$  decreases, no matter what the starting concentrations, as a reacting system moves toward equilibrium (§20.4)
- The distinction between product-favored and reactant-favored reactions (§20.4)
- Calculating  $\Delta S_{\text{sys}}^\circ$  for a phase change (SP 20.2)
- Calculating  $\Delta S_{\text{sys}}^\circ$  for a change in temperature (SP 20.3)
- Predicting relative  $S^\circ$  values of systems (§20.1 and SP 20.4)
- Calculating  $\Delta S_{\text{rxn}}^\circ$  for a chemical change (SP 20.5)
- Determining reaction spontaneity from  $\Delta S_{\text{surr}}$  and  $\Delta H_{\text{sys}}^\circ$  (SP 20.6)
- Calculating  $\Delta G_{\text{rxn}}^\circ$  from  $\Delta H_{\text{f}}^\circ$  and  $S^\circ$  values (SP 20.7)
- Calculating  $\Delta G_{\text{rxn}}^\circ$  from  $\Delta G_{\text{f}}^\circ$  values (SP 20.8)
- Using molecular scenes to determine the signs of  $\Delta H$ ,  $\Delta S$ , and  $\Delta G$  (SP 20.9)
- Determining the effect of temperature on  $\Delta G$  (SP 20.10)
- Calculating the temperature at which a reaction becomes spontaneous (§20.3 and SP 20.11)
- Calculating  $K$  from  $\Delta G^\circ$ , and vice versa (§20.4 and SP 20.12)
- Using  $\Delta G^\circ$  and  $Q$  to calculate  $\Delta G$  at any conditions (SPs 20.13, 20.14)

### Master These Skills

- Calculating  $\Delta S_{\text{sys}}^\circ$  for an isothermal change in the volume of a gas (SP 20.1)

### Key Terms

Page numbers appear in parentheses.

adenosine triphosphate (ATP) (925)	reversible process (901)	standard free energy change ( $\Delta G^\circ$ ) (917)	third law of thermodynamics (905)
coupling of reactions (924)	second law of thermodynamics (905)	standard free energy of formation ( $\Delta G_{\text{f}}^\circ$ ) (918)	Trouton's rule (902)
entropy ( $S$ ) (898)	spontaneous change (895)	standard molar entropy ( $S^\circ$ ) (906)	
free energy ( $G$ ) (916)	standard entropy of reaction ( $\Delta S_{\text{rxn}}^\circ$ ) (910)		
isothermal process (901)			
microstate (898)			

### Key Equations and Relationships

Page numbers appear in parentheses.

**20.1** Quantifying entropy in terms of the number of microstates ( $W$ ) over which the energy of a system can be dispersed (898):

$$S = k \ln W$$

**20.2** Quantifying the entropy change in terms of heat absorbed (or released) in a reversible process (901):

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T}$$

**20.3** Quantifying the entropy change that results from an isothermal volume change of a gas exhibiting ideal behavior (901):

$$\Delta S_{\text{sys}} = nR \ln \frac{V_{\text{final}}}{V_{\text{initial}}}$$

**20.4** Quantifying the entropy change that results from an isothermal change in volume (expressed as a change in pressure) of a gas exhibiting ideal behavior (902):

$$\Delta S_{\text{sys}} = nR \ln \frac{P_{\text{initial}}}{P_{\text{final}}}$$

**20.5** Quantifying the entropy change that results from a phase change (902):

$$\Delta S_{\text{fus}} = \frac{\Delta H_{\text{fus}}}{T_{\text{f}}} \quad \text{and} \quad \Delta S_{\text{vap}} = \frac{\Delta H_{\text{vap}}}{T_{\text{b}}}$$

**20.6** Quantifying the entropy change that results from a change in temperature of a system at constant volume (904):

$$\Delta S_{\text{fus}} = nC_{V,m} \ln \frac{T_2}{T_1}$$

**20.7** Quantifying the entropy change that results from a change in temperature of a system at constant pressure (904):

$$\Delta S_{\text{fus}} = nC_{P,m} \ln \frac{T_2}{T_1}$$

**20.8** Stating the second law of thermodynamics, for a spontaneous process (905):

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} > 0$$

**20.9** Calculating the standard entropy of reaction from the standard molar entropies of reactants and products (911):

$$\Delta S_{\text{rxn}}^\circ = \sum mS_{\text{products}}^\circ - \sum nS_{\text{reactants}}^\circ$$

**20.10** Relating the entropy change in the surroundings to the enthalpy change of the system and the temperature (913):

$$\Delta S_{\text{surr}} = -\frac{\Delta H_{\text{sys}}}{T}$$

**20.11** Expressing the free energy change of the system in terms of its component enthalpy and entropy changes (Gibbs equation) (917):

$$\Delta G_{\text{sys}} = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}}$$

**20.12** Calculating the standard free energy change from standard enthalpy and entropy changes (917):

$$\Delta G_{\text{sys}}^\circ = \Delta H_{\text{sys}}^\circ - T\Delta S_{\text{sys}}^\circ$$

**20.13** Calculating the standard free energy change from the standard free energies of formation (918):

$$\Delta G_{\text{rxn}}^\circ = \sum m\Delta G_{\text{f}}^\circ(\text{products}) - \sum n\Delta G_{\text{f}}^\circ(\text{reactants})$$

**20.14** Relating the free energy change to the maximum work a system can do (919):

$$\Delta G = w_{\max}$$

**20.15** Finding the temperature at which a reaction becomes spontaneous (923):

$$T = \frac{\Delta H}{\Delta S}$$

**20.16** Expressing the free energy change in terms of  $Q$  and  $K$  (926):

$$\Delta G = RT \ln \frac{Q}{K} = RT \ln Q - RT \ln K$$

**20.17** Expressing the free energy change with  $Q$  at standard-state conditions (927):

$$\Delta G^\circ = -RT \ln K$$

**20.18** Expressing the free energy change for nonstandard initial conditions (928):

$$\Delta G = \Delta G^\circ + RT \ln Q$$

### BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

**20.1A** Amount (mol) of  $N_2 = 200.0 \text{ g } N_2 \times \frac{1 \text{ mol } N_2}{28.02 \text{ g } N_2}$   
 $= 7.138 \text{ mol } N_2$

$$\Delta S_{\text{sys}} = nR \ln \frac{P_{\text{initial}}}{P_{\text{final}}} = 7.138 \text{ mol} \times 8.314 \text{ J/mol}\cdot\text{K} \times \ln \frac{0.715 \text{ atm}}{1.16 \text{ atm}}$$

$$= -28.7 \text{ J/K}$$

**20.1B** Amount (mol) of  $CO_2 = 100. \text{ g } CO_2 \times \frac{1 \text{ mol } CO_2}{44.01 \text{ g } CO_2}$   
 $= 2.27 \text{ mol } CO_2$

$$\Delta S_{\text{sys}} = nR \ln \frac{V_{\text{final}}}{V_{\text{initial}}} = 2.27 \text{ mol} \times 8.314 \text{ J/mol}\cdot\text{K} \times \ln \frac{4.75 \text{ L}}{3.35 \text{ L}}$$

$$= 6.59 \text{ J/K}$$

**20.2A**

$$\Delta H (\text{J}) = 34.0 \text{ g } C_3H_6O \times \frac{1 \text{ mol } C_3H_6O}{58.08 \text{ g } C_3H_6O} \times \frac{31.3 \text{ kJ}}{1 \text{ mol } C_3H_6O} \times \frac{10^3 \text{ J}}{1 \text{ kJ}}$$

$$= 18,323 \text{ kJ}$$

$$\Delta S = \frac{\Delta H_{\text{vap}}}{T_b} = \frac{18,323 \text{ kJ}}{329.4 \text{ K}} = 55.6 \text{ J/K}$$

**20.2B**

$$\Delta H (\text{J}) = 112 \text{ g } C_2H_5OH \times \frac{1 \text{ mol } C_2H_5OH}{46.07 \text{ g } C_2H_5OH} \times \frac{-5.02 \text{ kJ}}{1 \text{ mol } C_2H_5OH}$$

$$\times \frac{10^3 \text{ J}}{1 \text{ kJ}}$$

$$= -12,204 \text{ J}$$

$$\Delta S = \frac{\Delta H_{\text{fus}}}{T_f} = \frac{-12,204 \text{ kJ}}{159 \text{ K}} = -76.8 \text{ J/K}$$

Note that since the value of 5.02 kJ/mol is  $\Delta H_{\text{fus}}$  for melting solid  $C_2H_5OH$ , -5.02 kJ/mol is the value for the opposite process of freezing  $C_2H_5OH$ . Energy is required to melt the solid; the same amount of energy is released when the liquid freezes.

**20.3A** Amount (mol) of  $N_2 = 375 \text{ g } N_2 \times \frac{1 \text{ mol } N_2}{28.02 \text{ g } N_2}$   
 $= 13.4 \text{ mol } N_2$

$$\Delta S_{\text{sys}} = nC_{V,m} \ln \frac{T_2}{T_1} = 13.4 \text{ mol} \times 20.8 \text{ J/mol}\cdot\text{K} \times \ln \frac{273 \text{ K}}{298 \text{ K}}$$

$$= -24.4 \text{ J/K}$$

**20.3B**

Amount (mol) of  $H_2O = 100. \text{ g } H_2O \times \frac{1 \text{ mol } H_2O}{18.02 \text{ g } H_2O} = 5.55 \text{ mol } H_2O$

$$T_2 = T_1 \times e^{\Delta S_{\text{sys}}/nC_{P,m}} = 298 \times e^{(70.9 \text{ J/K})/(5.55 \text{ mol} \times 75.3 \text{ J/mol}\cdot\text{K})}$$

$$T_2 = 353 \text{ K} = 80.^\circ\text{C}$$

**20.4A** (a)  $PCl_5(g)$ : higher molar mass and more complex molecule; (b)  $BaCl_2(s)$ : higher molar mass; (c)  $Br_2(g)$ : gases have more freedom of motion and dispersal of energy than liquids.

**20.4B** (a)  $LiBr(aq)$ : same number of ions, but lower molar mass of ions; (b) quartz: the particles have less freedom of motion in the crystalline structure; (c) cyclohexane: molecule with no side chain has less freedom of motion.

**20.5A** (a)  $4NO(g) \rightarrow N_2O(g) + N_2O_3(g)$   
 $\Delta n_{\text{gas}} = -2$ , so  $\Delta S_{\text{rxn}}^\circ < 0$   
 $\Delta S_{\text{rxn}}^\circ = [(1 \text{ mol } N_2O)(219.7 \text{ J/mol}\cdot\text{K})$   
 $+ (1 \text{ mol } N_2O_3)(314.7 \text{ J/mol}\cdot\text{K})$   
 $- [(4 \text{ mol } NO)(210.65 \text{ J/mol}\cdot\text{K})]$   
 $= -308.2 \text{ J/K}$

(b)  $CH_3OH(g) \rightarrow CO(g) + 2H_2(g)$   
 $\Delta n_{\text{gas}} = 2$ , so  $\Delta S_{\text{rxn}}^\circ > 0$   
 $\Delta S_{\text{rxn}}^\circ = [(1 \text{ mol } CO)(197.5 \text{ J/mol}\cdot\text{K})$   
 $+ (2 \text{ mol } H_2)(130.6 \text{ J/mol}\cdot\text{K})$   
 $- [(1 \text{ mol } CH_3OH)(238 \text{ J/mol}\cdot\text{K})]$   
 $= 221 \text{ J/K}$

**20.5B** (a)  $2NaOH(s) + CO_2(g) \rightarrow Na_2CO_3(s) + H_2O(l)$   
 $\Delta n_{\text{gas}} = -1$ , so  $\Delta S_{\text{rxn}}^\circ < 0$   
 $\Delta S_{\text{rxn}}^\circ = [(1 \text{ mol } H_2O)(69.940 \text{ J/mol}\cdot\text{K})$   
 $+ (1 \text{ mol } Na_2CO_3)(139 \text{ J/mol}\cdot\text{K})$   
 $- [(1 \text{ mol } CO_2)(213.7 \text{ J/mol}\cdot\text{K})$   
 $+ (2 \text{ mol } NaOH)(64.454 \text{ J/mol}\cdot\text{K})]$   
 $= -134 \text{ J/K}$

(b)  $2Fe(s) + 3H_2O(g) \rightarrow Fe_2O_3(s) + 3H_2(g)$   
 $\Delta n_{\text{gas}} = 0$ , so cannot predict sign of  $\Delta S_{\text{rxn}}^\circ$   
 $\Delta S_{\text{rxn}}^\circ = [(1 \text{ mol } Fe_2O_3)(87.400 \text{ J/mol}\cdot\text{K})$   
 $+ (3 \text{ mol } H_2)(130.6 \text{ J/mol}\cdot\text{K})$   
 $- [(2 \text{ mol } Fe)(27.3 \text{ J/mol}\cdot\text{K})$   
 $+ (3 \text{ mol } H_2O)(188.72 \text{ J/mol}\cdot\text{K})]$   
 $= -141.6 \text{ J/K}$

**20.6A** To find  $\Delta S_{\text{surr}}$ , use  $\Delta H_f^\circ$  values to calculate  $\Delta H_{\text{rxn}}^\circ$  and divide it by  $T$ :

$$\Delta H_{\text{rxn}}^\circ = [(4 \text{ mol } PCl_3)(-287 \text{ kJ/mol})$$

$$- [(1 \text{ mol } P_4)(0 \text{ kJ/mol}) + (6 \text{ mol } Cl_2)(0 \text{ kJ/mol})]$$

$$= -1148 \text{ kJ}$$

$$\Delta S_{\text{surr}} = -\frac{\Delta H_{\text{rxn}}^\circ}{T} = -\frac{(-1148 \text{ kJ})(1000 \text{ J/1 kJ})}{298 \text{ K}} = 3850 \text{ J/K}$$

To find  $\Delta S_{\text{univ}}$ , use  $S^\circ$  values to calculate  $\Delta S_{\text{rxn}}^\circ$  and add it to  $\Delta S_{\text{surr}}$ :

$$\begin{aligned}\Delta S_{\text{rxn}}^{\circ} &= [(4 \text{ mol PCl}_3)(312 \text{ J/mol}\cdot\text{K}) \\ &\quad - [(1 \text{ mol P}_4)(41.1 \text{ J/mol}\cdot\text{K}) \\ &\quad + (6 \text{ mol Cl}_2)(223.0 \text{ J/mol}\cdot\text{K})] \\ &= -131 \text{ J/K}\end{aligned}$$

$$\Delta S_{\text{univ}}^{\circ} = \Delta S_{\text{surr}} + \Delta S_{\text{rxn}}^{\circ} = 3850 \text{ J/K} + (-131 \text{ J/K}) = 3719 \text{ J/K}$$

Reaction is spontaneous at 298 K since  $\Delta S_{\text{univ}}^{\circ}$  is positive.

Use  $S^{\circ}$  values to calculate  $\Delta S_{\text{rxn}}^{\circ}$  and  $\Delta H_{\text{rxn}}^{\circ}$  values to calculate  $\Delta H_{\text{rxn}}^{\circ}$ ; divide  $\Delta H_{\text{rxn}}^{\circ}$  by  $T$  to obtain  $\Delta S_{\text{surr}}^{\circ}$  and add that value to  $\Delta S_{\text{rxn}}^{\circ}$  to obtain  $\Delta S_{\text{univ}}^{\circ}$ .

$$\begin{aligned}\Delta S_{\text{rxn}}^{\circ} &= [(1 \text{ mol Fe}_2\text{O}_3)(87.400 \text{ J/mol}\cdot\text{K}) \\ &\quad - [(2 \text{ mol FeO})(60.75 \text{ J/mol}\cdot\text{K}) \\ &\quad + (\frac{1}{2} \text{ mol O}_2)(205.0 \text{ J/mol}\cdot\text{K})] \\ &= -136.6 \text{ J/K}\end{aligned}$$

$$\begin{aligned}\Delta H_{\text{rxn}}^{\circ} &= [(1 \text{ mol Fe}_2\text{O}_3)(-825.5 \text{ kJ/mol}) \\ &\quad - [(2 \text{ mol FeO})(-272.0 \text{ kJ/mol}) + (\frac{1}{2} \text{ mol O}_2)(0 \text{ kJ/mol})] \\ &= -281.5 \text{ kJ}\end{aligned}$$

$$\Delta S_{\text{surr}}^{\circ} = -\frac{\Delta H_{\text{rxn}}^{\circ}}{T} = -\frac{(-281.5 \text{ kJ})(1000 \text{ J/1 kJ})}{298 \text{ K}} = +945 \text{ J/K}$$

$$\Delta S_{\text{univ}}^{\circ} = \Delta S_{\text{rxn}}^{\circ} + \Delta S_{\text{surr}}^{\circ} = -136.6 \text{ J/K} + 945 \text{ J/K} = 808 \text{ J/K}$$

Reaction is spontaneous at 298 K since  $\Delta S_{\text{univ}}^{\circ}$  is positive.

**20.7A** Using  $\Delta H_{\text{f}}^{\circ}$  and  $S^{\circ}$  values from Appendix B:

$$\begin{aligned}\Delta H_{\text{rxn}}^{\circ} &= [(2 \text{ mol NOCl})(51.71 \text{ kJ/mol}) \\ &\quad - [(2 \text{ mol NO})(90.29 \text{ kJ/mol}) \\ &\quad + (1 \text{ mol Cl}_2)(0 \text{ kJ/mol})] \\ &= -77.16 \text{ kJ}\end{aligned}$$

$$\begin{aligned}\Delta S_{\text{rxn}}^{\circ} &= [(2 \text{ mol NOCl})(261.6 \text{ J/mol}\cdot\text{K}) \\ &\quad - [(2 \text{ mol NO})(210.65 \text{ J/mol}\cdot\text{K}) \\ &\quad + (1 \text{ mol Cl}_2)(223.0 \text{ J/mol}\cdot\text{K})] \\ &= -121.1 \text{ J/K}\end{aligned}$$

$$\begin{aligned}\Delta G_{\text{rxn}}^{\circ} &= \Delta H_{\text{rxn}}^{\circ} - T\Delta S_{\text{rxn}}^{\circ} \\ &= -77.16 \text{ kJ} - [(298 \text{ K})(-121.1 \text{ J/K})(1 \text{ kJ}/1000 \text{ J})] \\ &= -41.1 \text{ kJ}\end{aligned}$$

**20.7B** Using  $\Delta H_{\text{f}}^{\circ}$  and  $S^{\circ}$  values from Appendix B:

$$\begin{aligned}\Delta H_{\text{rxn}}^{\circ} &= [(4 \text{ mol NO})(90.29 \text{ kJ/mol}) \\ &\quad + (6 \text{ mol H}_2\text{O})(-241.826 \text{ kJ/mol}) \\ &\quad - [(4 \text{ mol NH}_3)(-45.9 \text{ kJ/mol}) \\ &\quad + (5 \text{ mol O}_2)(0 \text{ kJ/mol})] \\ &= -906.2 \text{ kJ}\end{aligned}$$

$$\begin{aligned}\Delta S_{\text{rxn}}^{\circ} &= [(4 \text{ mol NO})(210.65 \text{ J/mol}\cdot\text{K}) \\ &\quad + (6 \text{ mol H}_2\text{O})(188.72 \text{ J/mol}\cdot\text{K}) \\ &\quad - [(4 \text{ mol NH}_3)(193 \text{ J/mol}\cdot\text{K}) \\ &\quad + (5 \text{ mol O}_2)(205.0 \text{ J/mol}\cdot\text{K})] \\ &= 178 \text{ J/K}\end{aligned}$$

$$\begin{aligned}\Delta G_{\text{rxn}}^{\circ} &= \Delta H_{\text{rxn}}^{\circ} - T\Delta S_{\text{rxn}}^{\circ} \\ &= -906.2 \text{ kJ} - [(298 \text{ K})(178 \text{ J/K})(1 \text{ kJ}/1000 \text{ J})] \\ &= -959 \text{ kJ}\end{aligned}$$

**20.8A** (a) Using  $\Delta G_{\text{f}}^{\circ}$  values from Appendix B:

$$\begin{aligned}\Delta G_{\text{rxn}}^{\circ} &= [(2 \text{ mol NOCl})(66.07 \text{ kJ/mol}) \\ &\quad - [(2 \text{ mol NO})(86.60 \text{ kJ/mol}) \\ &\quad + (1 \text{ mol Cl}_2)(0 \text{ kJ/mol})] \\ &= -41.06 \text{ kJ}\end{aligned}$$

(b) Using  $\Delta G_{\text{f}}^{\circ}$  values from Appendix B:

$$\begin{aligned}\Delta G_{\text{rxn}}^{\circ} &= [(2 \text{ mol Fe})(0 \text{ kJ/mol}) \\ &\quad + (3 \text{ mol H}_2\text{O})(-228.60 \text{ kJ/mol}) \\ &\quad - [(3 \text{ mol H}_2)(0 \text{ kJ/mol}) \\ &\quad + (1 \text{ mol Fe}_2\text{O}_3)(-743.6 \text{ kJ/mol})] \\ &= 57.8 \text{ kJ}\end{aligned}$$

**20.8B** (a) Using  $\Delta G_{\text{f}}^{\circ}$  values from Appendix B:

$$\begin{aligned}\Delta G_{\text{rxn}}^{\circ} &= [(4 \text{ mol NO})(86.60 \text{ kJ/mol}) \\ &\quad + (6 \text{ mol H}_2\text{O})(-228.60 \text{ kJ/mol})] \\ &\quad - [(4 \text{ mol NH}_3)(-16 \text{ kJ/mol}) \\ &\quad + (5 \text{ mol O}_2)(0 \text{ kJ/mol})] \\ &= -961 \text{ kJ}\end{aligned}$$

(b) Using  $\Delta G_{\text{f}}^{\circ}$  values from Appendix B:

$$\begin{aligned}\Delta G_{\text{rxn}}^{\circ} &= (2 \text{ mol CO})(-137.2 \text{ kJ/mol}) \\ &\quad - [(2 \text{ mol C})(0 \text{ kJ/mol}) \\ &\quad + (1 \text{ mol O}_2)(0 \text{ kJ/mol})] \\ &= -274.4 \text{ kJ}\end{aligned}$$

**20.9A** (a) More moles of gas are present after the reaction, so  $\Delta S > 0$ . (b) The problem says the reaction is spontaneous ( $\Delta G < 0$ ) only above 325°C, which implies high  $T$ . If  $\Delta S > 0$ ,  $-T\Delta S < 0$ , so  $\Delta G$  will become negative at higher  $T$  only if  $\Delta H > 0$ .

**20.9B** (a) A solid forms a gas and a liquid, so  $\Delta S > 0$ , and a crystalline array breaks down, so  $\Delta H > 0$ . (b) For the reaction to occur spontaneously ( $\Delta G < 0$ ),  $-T\Delta S$  must be greater than  $\Delta H$ , which would occur only at higher  $T$ .

**20.10A** (a)  $\Delta G = \Delta H - T\Delta S$

$$\begin{aligned}&= -192.7 \text{ kJ} - [(298 \text{ K})(-308.2 \text{ J/K})(1 \text{ kJ}/1000 \text{ J})] \\ &= -100.9 \text{ kJ}\end{aligned}$$

The reaction is spontaneous at 298 K.

(b) As  $T$  increases,  $-T\Delta S$  becomes more positive, so the reaction becomes *less* spontaneous.

(c)  $\Delta G = \Delta H - T\Delta S$

$$\begin{aligned}&= -192.7 \text{ kJ} - [(500. + 273 \text{ K})(-308.2 \text{ J/K})(1 \text{ kJ}/1000 \text{ J})] \\ &= 45.5 \text{ kJ}\end{aligned}$$

**20.10B**  $\Delta G$  becomes negative at lower  $T$ , so  $\Delta H < 0$ ,  $\Delta S < 0$ , and  $-T\Delta S > 0$ . At the lower  $T$ , the negative  $\Delta H$  value becomes larger than the positive  $-T\Delta S$  value.

**20.11A**  $\Delta G = 0$  when  $T = \frac{\Delta H}{\Delta S} = \frac{(-192.7 \text{ kJ})(1000 \text{ J/1 kJ})}{-308.2 \text{ J/K}}$

$$= 625.2 \text{ K}$$

$$T (^{\circ}\text{C}) = 625.2 \text{ K} - 273.15 = 352.0^{\circ}\text{C}$$

**20.11B**

$$\begin{aligned}\Delta H &= [(1 \text{ mol})(\Delta H_{\text{f}}^{\circ} \text{ CaCO}_3)] - [(1 \text{ mol})(\Delta H_{\text{f}}^{\circ} \text{ CaO}) \\ &\quad + (1 \text{ mol})(\Delta H_{\text{f}}^{\circ} \text{ CO}_2)] \\ &= [(1 \text{ mol})(-1206.9 \text{ kJ/mol})] - [(1 \text{ mol})(-635.1 \text{ kJ/mol}) \\ &\quad + (1 \text{ mol})(-393.5 \text{ kJ/mol})] \\ &= -178.3 \text{ kJ}\end{aligned}$$

$$\begin{aligned}\Delta S &= [(1 \text{ mol})(S^{\circ} \text{ CaCO}_3)] - [(1 \text{ mol})(S^{\circ} \text{ CaO}) + (1 \text{ mol})(S^{\circ} \text{ CO}_2)] \\ &= [(1 \text{ mol})(92.9 \text{ J/mol}\cdot\text{K})] - [(1 \text{ mol})(38.2 \text{ J/mol}\cdot\text{K}) \\ &\quad + (1 \text{ mol})(213.7 \text{ J/mol}\cdot\text{K})] = -159.0 \text{ J/K}\end{aligned}$$

$$T = \frac{\Delta H}{\Delta S} = \frac{(-178.3 \text{ kJ})(1000 \text{ J/1 kJ})}{-159.0 \text{ J/K}} = 1121 \text{ K}$$

Reaction becomes spontaneous ( $\Delta G < 0$ ) at any  $T < 1121 \text{ K} - 273.15 = 848^{\circ}\text{C}$ .

**20.12A** Using  $\Delta G_{\text{f}}^{\circ}$  values from Appendix B,

$$\begin{aligned}\Delta G^{\circ} &= [(2 \text{ mol CO})(-137.2 \text{ kJ/mol})] - [(2 \text{ mol C})(0 \text{ kJ/mol}) \\ &\quad + (1 \text{ mol O}_2)(0 \text{ kJ/mol})] \\ &= -274.4 \text{ kJ}\end{aligned}$$

$$\ln K = -\frac{\Delta G^{\circ}}{RT} = -\frac{(-274.4 \text{ kJ})(1000 \text{ J/1 kJ})}{(8.314 \text{ J/mol}\cdot\text{K})(298 \text{ K})}$$

$$\begin{aligned}&= 111 \\ K &= e^{111} = 1.61 \times 10^{48}\end{aligned}$$

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

(continued)

**20.12B**  $K = 2.22 \times 10^{-15}$ , so  $\ln K = -33.7$ 

$$\Delta G^\circ = -RT \ln K = -(8.314 \text{ J/mol}\cdot\text{K})(298 \text{ K})(-33.7) \\ = 8.35 \times 10^4 \text{ J} = 83.5 \text{ kJ}$$

**20.13A** (a)  $A(g) + 3B(g) \rightleftharpoons AB_3(g)$ ;  $\Delta G^\circ = -4.6 \text{ kJ/mol}$ 

$$(b) \text{ For mixture 1, } Q_1 = \frac{[AB_3]}{[A][B]^3} = \frac{0.20}{(0.40)(0.80)^3} = 0.98$$

$$\text{For mixture 2, } Q_2 = \frac{(0.30)}{(0.30)(0.50)^3} = 8.0$$

$$\text{For mixture 3, } Q_3 = \frac{0.40}{(0.20)(0.20)^3} = 250$$

Mixture 2 is at equilibrium.

(c) Since  $Q_1 < K$ , the reaction is proceeding to the right (it is spontaneous) and so  $\Delta G_1 < 0$ ;  $\Delta G_2 = 0$  since this mixture is at equilibrium;  $Q_3 > K$ , so the reaction is proceeding to the left, not to the right, and  $\Delta G_3 > 0$ . Therefore,  $\Delta G_3 > \Delta G_2 > \Delta G_1$ .

**20.13B**

$$(a) \text{ For mixture 1, } Q_1 = \frac{[XY_2]^2}{[X_2][Y_2]^2} = \frac{(5.0)^2}{(2.0)(1.0)^2} = 12.5$$

$$\text{For mixture 2, } Q_2 = \frac{(4.0)^2}{(2.0)(2.0)^2} = 2.0$$

$$\text{For mixture 3, } Q_3 = \frac{(2.0)^2}{(4.0)(2.0)^2} = 0.25$$

Mixture 2 is at equilibrium.

(b) Since  $Q_1 > K$ , the reaction is proceeding to the left, not to the right, and  $\Delta G_1 > 0$ ;  $\Delta G_2 = 0$  since this mixture is at equilibrium;  $Q_3 < K$ , so the reaction is proceeding to the right (it is spontaneous), so  $\Delta G_3 < 0$ . Therefore,  $\Delta G_3 < \Delta G_2 < \Delta G_1$ . (c) Any reaction mixture moves spontaneously toward equilibrium, so both changes have a negative  $\Delta G$ .

**20.14A** (a)  $\Delta G^\circ = -RT \ln K$ , so

$$\ln K = -\frac{\Delta G^\circ}{RT} = -\frac{(-33.5 \text{ kJ})(1000 \text{ J/kJ})}{(8.314 \text{ J/mol}\cdot\text{K})(298 \text{ K})} = 13.521$$

$$K = e^{13.521} = 7.45 \times 10^5$$

$$(b) Q = \frac{[C_2H_5Cl]}{[C_2H_4][HCl]} = \frac{1.5}{(0.50)(1.0)} = 3.0$$

$$\Delta G = \Delta G^\circ + RT \ln Q \\ = -33.5 \text{ kJ} + [(8.314 \text{ J/mol}\cdot\text{K})(1 \text{ kJ}/1000 \text{ J})(298 \text{ K})(\ln 3.0)] \\ = -30.8 \text{ kJ}$$

**20.14B** (a)  $\Delta G^\circ = -RT \ln K$ 

$$= -8.314 \text{ J/mol}\cdot\text{K} \times \frac{1 \text{ kJ}}{1000 \text{ J}} \times 298 \text{ K} \\ \times \ln(2.3 \times 10^{-9}) \\ = 49 \text{ kJ/mol}$$

$$(b) Q = \frac{[H_3O^+][BrO^-]}{[HBrO]} = \frac{(6.0 \times 10^{-4})(0.10)}{0.20} = 3.0 \times 10^{-4}$$

$$\Delta G = \Delta G^\circ + RT \ln Q \\ = 49 \text{ kJ/mol} + [(8.314 \text{ J/mol}\cdot\text{K})(1 \text{ kJ}/1000 \text{ J})(298 \text{ K})(\ln 3.0 \times 10^{-4})] \\ = 29 \text{ kJ/mol}$$

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

**Note:** Unless stated otherwise, problems refer to systems at 298 K (25°C). Solving these problems may require values from Appendix B.

### The Second Law of Thermodynamics: Predicting Spontaneous Change

(Sample Problem 20.4)

#### Concept Review Questions

**20.1** Distinguish between the terms *spontaneous* and *instantaneous*. Give an example of a process that is spontaneous but very slow, and one that is very fast but not spontaneous.

**20.2** Distinguish between the terms *spontaneous* and *nonspontaneous*. Can a nonspontaneous process occur? Explain.

**20.3** State the first law of thermodynamics in terms of (a) the energy of the universe; (b) the creation or destruction of energy; (c) the energy change of system and surroundings. Does the first law reveal the direction of spontaneous change? Explain.

**20.4** State qualitatively the relationship between entropy and freedom of particle motion. Use this idea to explain why you will probably never (a) be suffocated because all the air near you has moved to the other side of the room; (b) see half the water in your cup of tea freeze while the other half boils.

**20.5** Why is  $\Delta S_{\text{vap}}$  of a substance always larger than  $\Delta S_{\text{fus}}$ ?

**20.6** How does the entropy of the surroundings change during an exothermic reaction? An endothermic reaction? Other than the examples in text, describe a spontaneous endothermic process.

**20.7** (a) What is the entropy of a perfect crystal at 0 K?

(b) Does entropy increase or decrease as the temperature rises?

(c) Why is  $\Delta H_f^\circ = 0$  but  $S^\circ > 0$  for an element?

(d) Why does Appendix B list  $\Delta H_f^\circ$  values but not  $\Delta S_f^\circ$  values?

#### Skill-Building Exercises (grouped in similar pairs)

**20.8** Which of these processes are spontaneous? (a) Water evaporates from a puddle. (b) A lion chases an antelope. (c) An isotope undergoes radioactive disintegration.

**20.9** Which of these processes are spontaneous? (a) Earth moves around the Sun. (b) A boulder rolls up a hill. (c) Sodium metal and chlorine gas form solid sodium chloride.

**20.10** Which of these processes are spontaneous? (a) Methane burns in air. (b) A teaspoonful of sugar dissolves in a cup of hot coffee. (c) A soft-boiled egg becomes raw.

**20.11** Which of these processes are spontaneous? (a) A satellite falls to Earth. (b) Water decomposes to  $\text{H}_2$  and  $\text{O}_2$  at 298 K and 1 atm. (c) Average car prices increase.

**20.12** Predict the sign of  $\Delta S_{\text{sys}}$  for each process: (a) A piece of wax melts. (b) Silver chloride precipitates from solution. (c) Dew forms on a lawn in the morning.

**20.13** Predict the sign of  $\Delta S_{\text{sys}}$  for each process: (a) Gasoline vapors mix with air in a car engine. (b) Hot air expands. (c) Humidity condenses in cold air.

**20.14** Predict the sign of  $\Delta S_{\text{sys}}$  for each process: (a) Alcohol evaporates. (b) A solid explosive converts to a gas. (c) Perfume vapors diffuse through a room.

**20.15** Predict the sign of  $\Delta S_{\text{sys}}$  for each process: (a) A pond freezes in winter. (b) Atmospheric  $\text{CO}_2$  dissolves in the ocean. (c) An apple tree bears fruit.

**20.16** Without using Appendix B, predict the sign of  $\Delta S^\circ$  for  
 (a)  $2\text{K}(s) + \text{F}_2(g) \rightarrow 2\text{KF}(s)$   
 (b)  $\text{NH}_3(g) + \text{HBr}(g) \rightarrow \text{NH}_4\text{Br}(s)$   
 (c)  $\text{NaClO}_3(s) \rightarrow \text{Na}^+(aq) + \text{ClO}_3^-(aq)$

**20.17** Without using Appendix B, predict the sign of  $\Delta S^\circ$  for  
 (a)  $\text{H}_2\text{S}(g) + \frac{1}{2}\text{O}_2(g) \rightarrow \frac{1}{8}\text{S}_8(s) + \text{H}_2\text{O}(g)$   
 (b)  $\text{HCl}(aq) + \text{NaOH}(aq) \rightarrow \text{NaCl}(aq) + \text{H}_2\text{O}(l)$   
 (c)  $2\text{NO}_2(g) \rightarrow \text{N}_2\text{O}_4(g)$

**20.18** Without using Appendix B, predict the sign of  $\Delta S^\circ$  for  
 (a)  $\text{CaCO}_3(s) + 2\text{HCl}(aq) \rightarrow \text{CaCl}_2(aq) + \text{H}_2\text{O}(l) + \text{CO}_2(g)$   
 (b)  $2\text{NO}(g) + \text{O}_2(g) \rightarrow 2\text{NO}_2(g)$   
 (c)  $2\text{KClO}_3(s) \rightarrow 2\text{KCl}(s) + 3\text{O}_2(g)$

**20.19** Without using Appendix B, predict the sign of  $\Delta S^\circ$  for  
 (a)  $\text{Ag}^+(aq) + \text{Cl}^-(aq) \rightarrow \text{AgCl}(s)$   
 (b)  $\text{KBr}(s) \rightarrow \text{KBr}(aq)$

(c)  $\text{CH}_3\text{CH}=\text{CH}_2(g) \rightarrow \text{H}_2\text{C} \begin{array}{c} \text{CH}_2 \\ \diagup \quad \diagdown \\ \text{---} \end{array} \text{CH}_2(g)$

**20.20** Predict the sign of  $\Delta S$  for each process:

(a)  $\text{C}_2\text{H}_5\text{OH}(g)$  (350 K and 500 torr)  $\rightarrow$   $\text{C}_2\text{H}_5\text{OH}(g)$  (350 K and 250 torr)  
 (b)  $\text{N}_2(g)$  (298 K and 1 atm)  $\rightarrow$   $\text{N}_2(aq)$  (298 K and 1 atm)  
 (c)  $\text{O}_2(aq)$  (303 K and 1 atm)  $\rightarrow$   $\text{O}_2(g)$  (303 K and 1 atm)

**20.21** Predict the sign of  $\Delta S$  for each process:

(a)  $\text{O}_2(g)$  (1.0 L at 1 atm)  $\rightarrow$   $\text{O}_2(g)$  (0.10 L at 10 atm)  
 (b)  $\text{Cu}(s)$  (350°C and 2.5 atm)  $\rightarrow$   $\text{Cu}(s)$  (450°C and 2.5 atm)  
 (c)  $\text{Cl}_2(g)$  (100°C and 1 atm)  $\rightarrow$   $\text{Cl}_2(g)$  (10°C and 1 atm)

**20.22** Predict which substance has greater molar entropy. Explain.

(a) Butane  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_3(g)$  or 2-butene  $\text{CH}_3\text{CH}=\text{CHCH}_3(g)$   
 (b)  $\text{Ne}(g)$  or  $\text{Xe}(g)$   
 (c)  $\text{CH}_4(g)$  or  $\text{CCl}_4(l)$

**20.23** Predict which substance has greater molar entropy. Explain.

(a)  $\text{NO}_2(g)$  or  $\text{N}_2\text{O}_4(g)$   
 (b)  $\text{CH}_3\text{OCH}_3(l)$  or  $\text{CH}_3\text{CH}_2\text{OH}(l)$   
 (c)  $\text{HCl}(g)$  or  $\text{HBr}(g)$

**20.24** Predict which substance has greater molar entropy. Explain.

(a)  $\text{CH}_3\text{OH}(l)$  or  $\text{C}_2\text{H}_5\text{OH}(l)$   
 (b)  $\text{KClO}_3(s)$  or  $\text{KClO}_3(aq)$   
 (c)  $\text{Na}(s)$  or  $\text{K}(s)$

**20.25** Predict which substance has greater molar entropy. Explain.

(a)  $\text{P}_4(g)$  or  $\text{P}_2(g)$   
 (b)  $\text{HNO}_3(aq)$  or  $\text{HNO}_3(l)$   
 (c)  $\text{CuSO}_4(s)$  or  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}(s)$

**20.26** Without consulting Appendix B, arrange each group in order of *increasing* standard molar entropy ( $S^\circ$ ). Explain.

(a) Graphite, diamond, charcoal  
 (b) Ice, water vapor, liquid water  
 (c)  $\text{O}_2$ ,  $\text{O}_3$ , O atoms

**20.27** Without consulting Appendix B, arrange each group in order of *increasing* standard molar entropy ( $S^\circ$ ). Explain.

(a) Glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ), sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ), ribose ( $\text{C}_5\text{H}_{10}\text{O}_5$ )  
 (b)  $\text{CaCO}_3$ ,  $\text{Ca} + \text{C} + \frac{3}{2}\text{O}_2$ ,  $\text{CaO} + \text{CO}_2$   
 (c)  $\text{SF}_6(g)$ ,  $\text{SF}_4(g)$ ,  $\text{S}_2\text{F}_{10}(g)$

**20.28** Without consulting Appendix B, arrange each group in order of *decreasing* standard molar entropy ( $S^\circ$ ). Explain.

(a)  $\text{ClO}_4^-(aq)$ ,  $\text{ClO}_2^-(aq)$ ,  $\text{ClO}_3^-(aq)$   
 (b)  $\text{NO}_2(g)$ ,  $\text{NO}(g)$ ,  $\text{N}_2(g)$   
 (c)  $\text{Fe}_2\text{O}_3(s)$ ,  $\text{Al}_2\text{O}_3(s)$ ,  $\text{Fe}_3\text{O}_4(s)$

**20.29** Without consulting Appendix B, arrange each group in order of *decreasing* standard molar entropy ( $S^\circ$ ). Explain.

(a) Mg metal, Ca metal, Ba metal  
 (b) Hexane ( $\text{C}_6\text{H}_{14}$ ), benzene ( $\text{C}_6\text{H}_6$ ), cyclohexane ( $\text{C}_6\text{H}_{12}$ )  
 (c)  $\text{PF}_2\text{Cl}_3(g)$ ,  $\text{PF}_5(g)$ ,  $\text{PF}_3(g)$

### Calculating the Change in Entropy of a Reaction

(Sample Problems 20.5 and 20.6)

### Concept Review Questions

**20.30** In the reaction depicted in the molecular scenes, X is red and Y is green.

(a) Write a balanced equation.  
 (b) Determine the sign of  $\Delta S_{\text{rxn}}$ .  
 (c) Which species has the highest molar entropy?

**20.31** Describe the equilibrium condition in terms of the entropy changes of a system and its surroundings. What does this description say about the entropy change of the universe?

**20.32** For the reaction  $\text{H}_2\text{O}(g) + \text{Cl}_2\text{O}(g) \rightarrow 2\text{HClO}(g)$ , you know  $\Delta S_{\text{rxn}}^\circ$  and  $S^\circ$  of  $\text{HClO}(g)$  and of  $\text{H}_2\text{O}(g)$ . Write an expression that can be used to determine  $S^\circ$  of  $\text{Cl}_2\text{O}(g)$ .

### Skill-Building Exercises (grouped in similar pairs)

**20.33** For each reaction, predict the sign and find the value of  $\Delta S_{\text{rxn}}^\circ$ :

(a)  $3\text{NO}(g) \rightarrow \text{N}_2\text{O}(g) + \text{NO}_2(g)$   
 (b)  $3\text{H}_2(g) + \text{Fe}_2\text{O}_3(s) \rightarrow 2\text{Fe}(s) + 3\text{H}_2\text{O}(g)$   
 (c)  $\text{P}_4(s) + 5\text{O}_2(g) \rightarrow \text{P}_4\text{O}_{10}(s)$

**20.34** For each reaction, predict the sign and find the value of  $\Delta S_{\text{rxn}}^{\circ}$ :

**20.35** Find  $\Delta S_{\text{rxn}}^{\circ}$  for the combustion of ethane ( $\text{C}_2\text{H}_6$ ) to carbon dioxide and gaseous water. Is the sign of  $\Delta S_{\text{rxn}}^{\circ}$  as expected?

**20.36** Find  $\Delta S_{\text{rxn}}^{\circ}$  for the combustion of methane to carbon dioxide and liquid water. Is the sign of  $\Delta S_{\text{rxn}}^{\circ}$  as expected?

**20.37** Find  $\Delta S_{\text{rxn}}^{\circ}$  for the reaction of nitrogen monoxide with hydrogen to form ammonia and water vapor. Is the sign of  $\Delta S_{\text{rxn}}^{\circ}$  as expected?

**20.38** Find  $\Delta S_{\text{rxn}}^{\circ}$  for the combustion of ammonia to nitrogen dioxide and water vapor. Is the sign of  $\Delta S_{\text{rxn}}^{\circ}$  as expected?

**20.39** (a) Find  $\Delta S_{\text{rxn}}^{\circ}$  for the formation of  $\text{Cu}_2\text{O}(\text{s})$  from its elements.

(b) Calculate  $\Delta S_{\text{univ}}$ , and state whether the reaction is spontaneous at 298 K.

**20.40** (a) Find  $\Delta S_{\text{rxn}}^{\circ}$  for the formation of  $\text{HI}(\text{g})$  from its elements.

(b) Calculate  $\Delta S_{\text{univ}}$ , and state whether the reaction is spontaneous at 298 K.

**20.41** (a) Find  $\Delta S_{\text{rxn}}^{\circ}$  for the formation of  $\text{CH}_3\text{OH}(\text{l})$  from its elements.

(b) Calculate  $\Delta S_{\text{univ}}$ , and state whether the reaction is spontaneous at 298 K.

**20.42** (a) Find  $\Delta S_{\text{rxn}}^{\circ}$  for the formation of  $\text{N}_2\text{O}(\text{g})$  from its elements.

(b) Calculate  $\Delta S_{\text{univ}}$ , and state whether the reaction is spontaneous at 298 K.

### Problems in Context

**20.43** Sulfur dioxide is released in the combustion of coal. Scrubbers use aqueous slurries of calcium hydroxide to remove the  $\text{SO}_2$  from flue gases. Write a balanced equation for this reaction and calculate  $\Delta S_{\text{rxn}}^{\circ}$  at 298 K [ $S^{\circ}$  of  $\text{CaSO}_3(\text{s}) = 101.4 \text{ J/mol}\cdot\text{K}$ ].

**20.44** Oxyacetylene welding is used to repair metal structures, including bridges, buildings, and even the Statue of Liberty. Calculate  $\Delta S_{\text{rxn}}^{\circ}$  for the combustion of 1 mol of acetylene ( $\text{C}_2\text{H}_2$ ).

### Entropy, Free Energy, and Work

(Sample Problems 20.7 to 20.11)

### Concept Review Questions

**20.45** What is the advantage of calculating free energy changes rather than entropy changes to determine reaction spontaneity?

**20.46** Given that  $\Delta G_{\text{sys}} = -T\Delta S_{\text{univ}}$ , explain how the sign of  $\Delta G_{\text{sys}}$  correlates with reaction spontaneity.

**20.47** (a) Is an endothermic reaction more likely to be spontaneous at higher temperatures or lower temperatures? Explain.

(b) The change depicted below occurs at constant pressure. Explain your answers to each of the following: (1) What is the sign of  $\Delta H_{\text{sys}}$ ? (2) What is the sign of  $\Delta S_{\text{sys}}$ ? (3) What is the

sign of  $\Delta S_{\text{surr}}$ ? (4) How does the sign of  $\Delta G_{\text{sys}}$  vary with temperature?

**20.48** Explain your answers to each of the following for the change depicted below. (a) What is the sign of  $\Delta H_{\text{sys}}$ ? (b) What is the sign of  $\Delta S_{\text{sys}}$ ? (c) What is the sign of  $\Delta S_{\text{surr}}$ ? (d) How does the sign of  $\Delta G_{\text{sys}}$  vary with temperature?

**20.49** With its components in their standard states, a certain reaction is spontaneous only at high  $T$ . What do you know about the signs of  $\Delta H^{\circ}$  and  $\Delta S^{\circ}$ ? Describe a process for which this is true.

**20.50** How can  $\Delta S^{\circ}$  for a reaction be relatively independent of  $T$  if  $S^{\circ}$  of each reactant and product increases with  $T$ ?

### Skill-Building Exercises (grouped in similar pairs)

**20.51** Calculate  $\Delta G^{\circ}$  for each reaction using  $\Delta G_f^{\circ}$  values:

**20.52** Calculate  $\Delta G^{\circ}$  for each reaction using  $\Delta G_f^{\circ}$  values:

**20.53** Find  $\Delta G^{\circ}$  for the reactions in Problem 20.51 using  $\Delta H_f^{\circ}$  and  $S^{\circ}$  values.

**20.54** Find  $\Delta G^{\circ}$  for the reactions in Problem 20.52 using  $\Delta H_f^{\circ}$  and  $S^{\circ}$  values.

**20.55** Consider the oxidation of carbon monoxide:

(a) Predict the signs of  $\Delta S^{\circ}$  and  $\Delta H^{\circ}$ . Explain.

(b) Calculate  $\Delta G^{\circ}$  by two different methods.

**20.56** Consider the combustion of butane gas:

(a) Predict the signs of  $\Delta S^{\circ}$  and  $\Delta H^{\circ}$ . Explain.

(b) Calculate  $\Delta G^{\circ}$  by two different methods.

**20.57** For the gaseous reaction of xenon and fluorine to form xenon hexafluoride:

(a) Calculate  $\Delta S^{\circ}$  at 298 K ( $\Delta H^{\circ} = -402 \text{ kJ/mol}$  and  $\Delta G^{\circ} = -280. \text{ kJ/mol}$ ).

(b) Assuming that  $\Delta S^{\circ}$  and  $\Delta H^{\circ}$  change little with temperature, calculate  $\Delta G^{\circ}$  at 500. K.

**20.58** For the gaseous reaction of carbon monoxide and chlorine to form phosgene ( $\text{COCl}_2$ ):

(a) Calculate  $\Delta S^\circ$  at 298 K ( $\Delta H^\circ = -220.$  kJ/mol and  $\Delta G^\circ = -206$  kJ/mol).

(b) Assuming that  $\Delta S^\circ$  and  $\Delta H^\circ$  change little with temperature, calculate  $\Delta G^\circ$  at 450. K.

**20.59** One reaction used to produce small quantities of pure  $\text{H}_2$  is

(a) Determine  $\Delta H^\circ$  and  $\Delta S^\circ$  for the reaction at 298 K.

(b) Assuming that these values are relatively independent of temperature, calculate  $\Delta G^\circ$  at 28°C, 128°C, and 228°C.

(c) What is the significance of the different values of  $\Delta G^\circ$ ?

(d) At what temperature (in K) does the reaction become spontaneous?

**20.60** A reaction that occurs in the internal combustion engine is

(a) Determine  $\Delta H^\circ$  and  $\Delta S^\circ$  for the reaction at 298 K.

(b) Assuming that these values are relatively independent of temperature, calculate  $\Delta G^\circ$  at 100.°C, 2560.°C, and 3540.°C.

(c) What is the significance of the different values of  $\Delta G^\circ$ ?

(d) At what temperature (in K) does the reaction become spontaneous?

### Problems in Context

**20.61** As a fuel,  $\text{H}_2(g)$  produces only nonpolluting  $\text{H}_2\text{O}(g)$  when it burns. Moreover, it combines with  $\text{O}_2(g)$  in a fuel cell (Chapter 21) to provide electrical energy.

(a) Calculate  $\Delta H^\circ$ ,  $\Delta S^\circ$ , and  $\Delta G^\circ$  per mole of  $\text{H}_2$  at 298 K.

(b) Is the spontaneity of this reaction dependent on  $T$ ? Explain.

(c) At what temperature does the reaction become spontaneous?

**20.62** The U.S. government requires automobile fuels to contain a renewable component. Fermentation of glucose from corn yields ethanol, which is added to gasoline to fulfill this requirement:

Calculate  $\Delta H^\circ$ ,  $\Delta S^\circ$ , and  $\Delta G^\circ$  for the reaction at 25°C. Is the spontaneity of this reaction dependent on  $T$ ? Explain.

### Free Energy, Equilibrium, and Reaction Direction

(Sample Problems 20.12 to 20.14)

### Concept Review Questions

**20.63** (a) If  $K \ll 1$  for a reaction, what do you know about the sign and magnitude of  $\Delta G^\circ$ ? (b) If  $\Delta G^\circ \ll 0$  for a reaction, what do you know about the magnitude of  $K$ ? Of  $Q$ ?

**20.64** How is the free energy change of a process related to the work that can be obtained from the process? Is this quantity of work obtainable in practice? Explain.

**20.65** The scenes and the graph relate to the reaction of  $\text{X}_2(g)$  (black) with  $\text{Y}_2(g)$  (orange) to form  $\text{XY}(g)$ . (a) If reactants and products are in their standard states, what quantity is represented on the graph by  $x$ ? (b) Which scene represents point 1? Explain. (c) Which scene represents point 2? Explain.

**20.66** What is the difference between  $\Delta G^\circ$  and  $\Delta G$ ? Under what circumstances does  $\Delta G = \Delta G^\circ$ ?

### Skill-Building Exercises (grouped in similar pairs)

**20.67** Calculate  $K$  at 298 K for each reaction:

**20.68** Calculate  $\Delta G^\circ$  at 298 K for each reaction:

**20.69** Calculate  $K$  at 298 K for each reaction:

**20.70** Calculate  $\Delta G^\circ$  at 298 K for each reaction:

**20.71** Use  $\Delta H^\circ$  and  $\Delta S^\circ$  values for the following process at 1 atm to find the normal boiling point of  $\text{Br}_2$ :

**20.72** Use  $\Delta H^\circ$  and  $\Delta S^\circ$  values to find the temperature at which these sulfur allotropes reach equilibrium at 1 atm:

**20.73** Use Appendix B to determine the  $K_{\text{sp}}$  of  $\text{Ag}_2\text{S}$ .

**20.74** Use Appendix B to determine the  $K_{\text{sp}}$  of  $\text{CaF}_2$ .

**20.75** For the reaction  $\text{I}_2(g) + \text{Cl}_2(g) \rightleftharpoons 2\text{ICl}(g)$ , calculate  $K_p$  at 25°C [ $\Delta G_f^\circ$  of  $\text{ICl}(g) = -6.075$  kJ/mol].

**20.76** For the reaction  $\text{CaCO}_3(s) \rightleftharpoons \text{CaO}(s) + \text{CO}_2(g)$ , calculate the equilibrium  $P_{\text{CO}_2}$  at 25°C.

**20.77** The  $K_{\text{sp}}$  of  $\text{PbCl}_2$  is  $1.7 \times 10^{-5}$  at 25°C. What is  $\Delta G^\circ$ ? Is it possible to prepare a solution that contains  $\text{Pb}^{2+}(aq)$  and  $\text{Cl}^-(aq)$ , at their standard-state concentrations?

**20.78** The  $K_{\text{sp}}$  of  $\text{ZnF}_2$  is  $3.0 \times 10^{-2}$  at 25°C. What is  $\Delta G^\circ$ ? Is it possible to prepare a solution that contains  $\text{Zn}^{2+}(aq)$  and  $\text{F}^-(aq)$  at their standard-state concentrations?

**20.79** The equilibrium constant for the reaction

is  $K_c = 9.1 \times 10^{-6}$  at 298 K.

(a) What is  $\Delta G^\circ$  at this temperature?

(b) If standard-state concentrations of the reactants and products are mixed, in which direction does the reaction proceed?

(c) Calculate  $\Delta G$  when  $[\text{Fe}^{3+}] = 0.20$  M,  $[\text{Hg}_2^{2+}] = 0.010$  M,  $[\text{Fe}^{2+}] = 0.010$  M, and  $[\text{Hg}_2^{2+}] = 0.025$  M. In which direction will the reaction proceed to achieve equilibrium?

**20.80** The formation constant for the reaction

is  $K_f = 5.6 \times 10^8$  at 25°C.

- (a) What is  $\Delta G^\circ$  at this temperature?  
 (b) If standard-state concentrations of the reactants and products are mixed, in which direction does the reaction proceed?  
 (c) Determine  $\Delta G$  when  $[\text{Ni}(\text{NH}_3)_6^{2+}] = 0.010 \text{ M}$ ,  $[\text{Ni}^{2+}] = 0.0010 \text{ M}$ , and  $[\text{NH}_3] = 0.0050 \text{ M}$ . In which direction will the reaction proceed to achieve equilibrium?

**20.81** The scenes below depict three gaseous mixtures in which A is reacting with itself to form  $A_2$ . Assume that each particle represents 0.10 mol and the volume is 0.10 L.

- (a) If  $K = 0.33$ , which mixture is at equilibrium? (b) Rank the mixtures from the most positive  $\Delta G$  to the most negative  $\Delta G$ .

**20.82** The scenes below depict three gaseous mixtures in which X (orange) and  $Y_2$  (black) are reacting to form XY and Y. Assume that each gas has a partial pressure of 0.10 atm.

- (a) If  $K = 4.5$ , which mixture is at equilibrium? (b) Rank the mixtures from the most positive  $\Delta G$  to the most negative  $\Delta G$ .

### Problems in Context

**20.83** High levels of ozone ( $\text{O}_3$ ) cause rubber to deteriorate, green plants to turn brown, and many people to have difficulty breathing.

- (a) Is the formation of  $\text{O}_3$  from  $\text{O}_2$  favored at all  $T$ , no  $T$ , high  $T$ , or low  $T$ ?  
 (b) Calculate  $\Delta G^\circ$  for this reaction at 298 K.  
 (c) Calculate  $\Delta G$  at 298 K for this reaction in urban smog where  $[\text{O}_2] = 0.21 \text{ atm}$  and  $[\text{O}_3] = 5 \times 10^{-7} \text{ atm}$ .

**20.84** A  $\text{BaSO}_4$  slurry is ingested before the gastrointestinal tract is x-rayed because it is opaque to x-rays and defines the contours of the tract.  $\text{Ba}^{2+}$  ion is toxic, but the compound is nearly insoluble. If  $\Delta G^\circ$  at 37°C (body temperature) is 59.1 kJ/mol for the dissolution,

what is  $[\text{Ba}^{2+}]$  in the intestinal tract? (Assume that the only source of  $\text{SO}_4^{2-}$  is the ingested slurry.)

### Comprehensive Problems

**20.85** According to advertisements, “a diamond is forever.”

- (a) Calculate  $\Delta H^\circ$ ,  $\Delta S^\circ$ , and  $\Delta G^\circ$  at 298 K for the phase change  
 Diamond  $\rightarrow$  graphite

(b) Given the conditions under which diamond jewelry is normally kept, argue for and against the statement in the ad.

(c) Given the answers in part (a), what would need to be done to make synthetic diamonds from graphite?

(d) Assuming  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change with temperature, can graphite be converted to diamond spontaneously at 1 atm?

**20.86** Replace each question mark with the correct information:

	$\Delta S_{\text{rxn}}$	$\Delta H_{\text{rxn}}$	$\Delta G_{\text{rxn}}$	Comment
(a)	+	−	−	?
(b)	?	0	−	Spontaneous
(c)	−	+	?	Not spontaneous
(d)	0	?	−	Spontaneous
(e)	?	0	+	?
(f)	+	+	?	$T\Delta S > \Delta H$

**20.87** Among the many complex ions of cobalt are the following:

where “en” stands for ethylenediamine,  $\text{H}_2\text{NCH}_2\text{CH}_2\text{NH}_2$ . Six Co—N bonds are broken and six Co—N bonds are formed in this reaction, so  $\Delta H_{\text{rxn}}^\circ \approx 0$ ; yet  $K > 1$ . What are the signs of  $\Delta S^\circ$  and  $\Delta G^\circ$ ? What drives the reaction?

**20.88** What is the change in entropy when 0.200 mol of potassium freezes at 63.7°C ( $\Delta H_{\text{fus}} = 2.39 \text{ kJ/mol}$ )?

**20.89** Is each statement true or false? If false, correct it.

- (a) All spontaneous reactions occur quickly.  
 (b) The reverse of a spontaneous reaction is nonspontaneous.  
 (c) All spontaneous processes release heat.  
 (d) The boiling of water at 100°C and 1 atm is spontaneous.  
 (e) If a process increases the freedom of motion of the particles of a system, the entropy of the system decreases.  
 (f) The energy of the universe is constant; the entropy of the universe decreases toward a minimum.  
 (g) All systems disperse their energy spontaneously.  
 (h) Both  $\Delta S_{\text{sys}}$  and  $\Delta S_{\text{surr}}$  equal zero at equilibrium.

**20.90** Hemoglobin carries  $\text{O}_2$  from the lungs to tissue cells, where the  $\text{O}_2$  is released. The protein is represented as Hb in its unoxylated form and as  $\text{Hb}\cdot\text{O}_2$  in its oxygenated form. One reason CO is toxic is that it competes with  $\text{O}_2$  in binding to Hb:

- (a) If  $\Delta G^\circ \approx -14 \text{ kJ}$  at 37°C (body temperature), what is the ratio of  $[\text{Hb}\cdot\text{CO}]$  to  $[\text{Hb}\cdot\text{O}_2]$  at 37°C with  $[\text{O}_2] = [\text{CO}]$ ?  
 (b) How is Le Châtelier’s principle used to treat CO poisoning?

**20.91** Magnesia ( $\text{MgO}$ ) is used for fire brick, crucibles, and furnace linings because of its high melting point. It is produced by decomposing magnesite ( $\text{MgCO}_3$ ) at around 1200°C.

- (a) Write a balanced equation for magnesite decomposition.  
 (b) Use  $\Delta H^\circ$  and  $S^\circ$  values to find  $\Delta G^\circ$  at 298 K.  
 (c) Assuming that  $\Delta H^\circ$  and  $S^\circ$  do not change with temperature, find the minimum temperature at which the reaction is spontaneous.  
 (d) Calculate the equilibrium  $P_{\text{CO}_2}$  above  $\text{MgCO}_3$  at 298 K.  
 (e) Calculate the equilibrium  $P_{\text{CO}_2}$  above  $\text{MgCO}_3$  at 1200 K.

**20.92** To prepare nuclear fuel,  $\text{U}_3\text{O}_8$  (“yellow cake”) is converted to  $\text{UO}_2(\text{NO}_3)_2$ , which is then converted to  $\text{UO}_3$  and finally  $\text{UO}_2$ . The fuel is enriched (the proportion of the  $^{235}\text{U}$  is increased) by a two-step conversion of  $\text{UO}_2$  into  $\text{UF}_6$ , a volatile solid, followed by a gaseous-diffusion separation of the  $^{235}\text{U}$  and  $^{238}\text{U}$  isotopes:

Calculate  $\Delta G^\circ$  for the overall process at 85°C:

	$\Delta H_f^\circ$ (kJ/mol)	$S^\circ$ (J/mol·K)	$\Delta G_f^\circ$ (kJ/mol)
UO <sub>2</sub> (s)	-1085	77.0	-1032
UF <sub>4</sub> (s)	-1921	152	-1830
UF <sub>6</sub> (s)	-2197	225	-2068

**20.93** Methanol, a major industrial feedstock, is made by several catalyzed reactions, such as  $\text{CO}(g) + 2\text{H}_2(g) \rightarrow \text{CH}_3\text{OH}(l)$ .

- (a) Show that this reaction is thermodynamically feasible.  
 (b) Is it favored at low or at high temperatures?  
 (c) One concern about using CH<sub>3</sub>OH as an auto fuel is its oxidation in air to yield formaldehyde, CH<sub>2</sub>O(g), which poses a health hazard. Calculate  $\Delta G^\circ$  at 100.°C for this oxidation.

**20.94** (a) Write a balanced equation for the gaseous reaction between N<sub>2</sub>O<sub>5</sub> and F<sub>2</sub> to form NF<sub>3</sub> and O<sub>2</sub>. (b) Determine  $\Delta G_{\text{rxn}}^\circ$ . (c) Find  $\Delta G_{\text{rxn}}$  at 298 K if  $P_{\text{N}_2\text{O}_5} = P_{\text{F}_2} = 0.20$  atm,  $P_{\text{NF}_3} = 0.25$  atm, and  $P_{\text{O}_2} = 0.50$  atm.

**20.95** Consider the following reaction:

Given that  $S^\circ$  of NOBr(g) = 272.6 J/mol·K and that  $\Delta S_{\text{rxn}}^\circ$  and  $\Delta H_{\text{rxn}}^\circ$  are constant with temperature, find

- (a)  $\Delta S_{\text{rxn}}^\circ$  at 298 K                      (b)  $\Delta G_{\text{rxn}}^\circ$  at 373 K  
 (c)  $\Delta H_{\text{rxn}}^\circ$  at 373 K                      (d)  $\Delta H_f^\circ$  of NOBr at 298 K  
 (e)  $\Delta G_{\text{rxn}}^\circ$  at 298 K                      (f)  $\Delta G_f^\circ$  of NOBr at 298 K

**20.96** Hydrogenation is the addition of H<sub>2</sub> to double (or triple) carbon-carbon bonds. Peanut butter and most commercial baked goods include hydrogenated oils. Find  $\Delta H^\circ$ ,  $\Delta S^\circ$ , and  $\Delta G^\circ$  for the hydrogenation of ethene (C<sub>2</sub>H<sub>4</sub>) to ethane (C<sub>2</sub>H<sub>6</sub>) at 25°C.

**20.97** Styrene is produced by catalytic dehydrogenation of ethylbenzene at high temperature in the presence of superheated steam.

(a) Find  $\Delta H_{\text{rxn}}^\circ$ ,  $\Delta G_{\text{rxn}}^\circ$ , and  $\Delta S_{\text{rxn}}^\circ$ , given these data at 298 K:

Compound	$\Delta H_f^\circ$ (kJ/mol)	$\Delta G_f^\circ$ (kJ/mol)	$S^\circ$ (J/mol·K)
Ethylbenzene, C <sub>6</sub> H <sub>5</sub> —CH <sub>2</sub> CH <sub>3</sub>	-12.5	119.7	255
Styrene, C <sub>6</sub> H <sub>5</sub> —CH=CH <sub>2</sub>	103.8	202.5	238

- (b) At what temperature is the reaction spontaneous?  
 (c) What are  $\Delta G_{\text{rxn}}^\circ$  and  $K$  at 600.°C?  
 (d) With 5.0 parts steam to 1.0 part ethylbenzene in the reactant mixture and the total pressure kept constant at 1.3 atm, what is  $\Delta G$  at 50.% conversion, that is, when 50.% of the ethylbenzene has reacted?

**20.98** Propylene (propene; CH<sub>3</sub>CH=CH<sub>2</sub>) is used to produce polypropylene and many other chemicals. Although most propylene is obtained from the cracking of petroleum, about 2% is produced by catalytic dehydrogenation of propane (CH<sub>3</sub>CH<sub>2</sub>CH<sub>3</sub>):

Because this reaction is endothermic, heaters are placed between the reactor vessels to maintain the required temperature.

- (a) If the molar entropy,  $S^\circ$ , of propylene is 267.1 J/mol·K, find its entropy of formation,  $S_f^\circ$ .  
 (b) Find  $\Delta G_f^\circ$  of propylene ( $\Delta H_f^\circ$  for propylene = 20.4 kJ/mol).  
 (c) Calculate  $\Delta H_{\text{rxn}}^\circ$  and  $\Delta G_{\text{rxn}}^\circ$  for the dehydrogenation.  
 (d) What is the theoretical yield of propylene at 580°C if the initial pressure of propane is 1.00 atm?  
 (e) Would the yield change if the reactor walls were permeable to H<sub>2</sub>? Explain.  
 (f) At what temperature is the dehydrogenation spontaneous, with all substances in the standard state?

**Note:** Problems 20.99 and 20.100 relate to the thermodynamics of adenosine triphosphate (ATP). Refer to the Chemical Connections essay at the end of Section 20.3.

**20.99** Find  $K$  for (a) the hydrolysis of ATP, (b) the dehydration-condensation to form glucose phosphate, and (c) the coupled reaction between ATP and glucose. (d) How does each  $K$  change when  $T$  changes from 25°C to 37°C?

**20.100** Energy from ATP hydrolysis drives many nonspontaneous cell reactions:

Energy for the reverse process comes ultimately from glucose metabolism:

- (a) Find  $K$  for the hydrolysis of ATP at 37°C.  
 (b) Find  $\Delta G_{\text{rxn}}^\circ$  for metabolism of 1 mol of glucose.  
 (c) How many moles of ATP can be produced by metabolism of 1 mol of glucose?  
 (d) If 36 mol of ATP is formed, what is the actual yield?

**20.101** From the following reaction and data, find (a)  $S^\circ$  of SOCl<sub>2</sub> and (b) the  $T$  at which the reaction becomes nonspontaneous:

	SO <sub>3</sub> (g)	SCl <sub>2</sub> (l)	SOCl <sub>2</sub> (l)	SO <sub>2</sub> (g)
$\Delta H_f^\circ$ (kJ/mol)	-396	-50.0	-245.6	-296.8
$S^\circ$ (J/mol·K)	256.7	184	—	248.1

**20.102** Write equations for the oxidation of Fe and of Al. Use  $\Delta G_f^\circ$  to determine whether either process is spontaneous at 25°C.

**20.103** The molecular scene depicts a gaseous equilibrium mixture at 460°C for the reaction of H<sub>2</sub> (blue) and I<sub>2</sub> (purple) to form HI. Each molecule represents 0.010 mol and the container volume is 1.0 L. (a) Is  $K_c > 1$ , = 1, or < 1? (b) Is  $K_p > K_c$ , =  $K_c$ , or <  $K_c$ ? (c) Calculate  $\Delta G_{\text{rxn}}^\circ$ . (d) How would the value of  $\Delta G_{\text{rxn}}^\circ$  change if the purple molecules represented H<sub>2</sub> and the blue I<sub>2</sub>? Explain.

**20.104** A key step in the metabolism of glucose for energy is the isomerization of glucose-6-phosphate (G6P) to fructose-6-phosphate (F6P):  $\text{G6P} \rightleftharpoons \text{F6P}$ ;  $K = 0.510$  at 298 K.

- (a) Calculate  $\Delta G^\circ$  at 298 K.  
 (b) Calculate  $\Delta G$  when  $Q$ , the [F6P]/[G6P] ratio, equals 10.0.  
 (c) Calculate  $\Delta G$  when  $Q = 0.100$ .  
 (d) Calculate  $Q$  if  $\Delta G = -2.50$  kJ/mol.

**20.105** A chemical reaction, such as HI forming from its elements, can reach equilibrium at many temperatures. In contrast, a phase change, such as ice melting, is in equilibrium at a given pressure and temperature. Each of the graphs below depicts  $G_{\text{sys}}$  vs. extent of change. (a) Which graph depicts how  $G_{\text{sys}}$  changes for the formation of HI? Explain. (b) Which graph depicts how  $G_{\text{sys}}$  changes as ice melts at 1°C and 1 atm? Explain.

**20.106** When heated, the DNA double helix separates into two random coil single strands. When cooled, the random coils reform the double helix: double helix  $\rightleftharpoons$  2 random coils.

- (a) What is the sign of  $\Delta S$  for the forward process? Why?  
 (b) Energy must be added to break H bonds and overcome dispersion forces between the strands. What is the sign of  $\Delta G$  for the forward process when  $T\Delta S$  is smaller than  $\Delta H$ ?  
 (c) Write an expression for  $T$  in terms of  $\Delta H$  and  $\Delta S$  when the reaction is at equilibrium. (This temperature is called the *melting temperature* of the nucleic acid.)

**20.107** In the process of respiration, glucose is oxidized completely. In fermentation,  $O_2$  is absent and glucose is broken down to ethanol and  $CO_2$ . Ethanol is oxidized to  $CO_2$  and  $H_2O$ .

- (a) Balance the following equations for these processes:

- (b) Calculate  $\Delta G_{rxn}^\circ$  for respiration of 1.00 g of glucose.  
 (c) Calculate  $\Delta G_{rxn}^\circ$  for fermentation of 1.00 g of glucose.  
 (d) Calculate  $\Delta G_{rxn}^\circ$  for oxidation of the ethanol from part (c).

**20.108** Consider the formation of ammonia:

- (a) Assuming that  $\Delta H^\circ$  and  $\Delta S^\circ$  are constant with temperature, find the temperature at which  $K_p = 1.00$ .  
 (b) Find  $K_p$  at 400.°C, a typical temperature for  $NH_3$  production.  
 (c) Given the lower  $K_p$  at the higher temperature, why are these conditions used industrially?

**20.109** Kyanite, sillimanite, and andalusite all have the formula  $Al_2SiO_5$ . Each is stable under different conditions (see the graph below). At the point where the three phases intersect:

- (a) Which mineral, if any, has the lowest free energy?  
 (b) Which mineral, if any, has the lowest enthalpy?  
 (c) Which mineral, if any, has the highest entropy?  
 (d) Which mineral, if any, has the lowest density?

**20.110** Acetylene is produced commercially by the partial oxidation of methane. At 1500°C and pressures of 1–10 bar, the yield of

acetylene is about 20%. The major side product is carbon monoxide, and some soot and carbon dioxide also form.

- (a) At what temperature is the desired reaction spontaneous:

(b) Acetylene can also be made by the reaction of its elements, carbon (graphite) and hydrogen. At what temperature is this formation reaction spontaneous?

- (c) Why must this reaction mixture be immediately cooled?

**20.111** Synthesis gas, a mixture that includes the fuels  $CO$  and  $H_2$ , is used to produce liquid hydrocarbons and methanol. It is made at pressures up to 100 atm by oxidation of methane followed by the steam re-forming and water-gas shift reactions. Because the process is exothermic, temperatures reach 950–1100°C, and the conditions are such that the amounts of  $H_2$ ,  $CO$ ,  $CO_2$ ,  $CH_4$ , and  $H_2O$  leaving the reactor are close to the equilibrium amounts for the steam re-forming and water-gas shift reactions:

- (a) At 1000.°C, what are  $\Delta G^\circ$  and  $\Delta H^\circ$  for the steam re-forming reaction and for the water-gas shift reaction?

(b) By doubling the steam re-forming step and adding it to the water-gas shift step, we obtain the following combined reaction:

Is this reaction spontaneous at 1000.°C in the standard state?

- (c) Is it spontaneous at 98 atm and 50.% conversion (when 50.% of the starting materials have reacted)?  
 (d) Is it spontaneous at 98 atm and 90.% conversion?

**20.112** Calculate the change in entropy when 10.0 g of  $CO_2$  isothermally expands from a volume of 6.15 L to 11.5 L. Assume that the gas behaves ideally.

**20.113** Calculate the change in entropy when the pressure of a 46.0 g sample of oxygen gas is increased from 625 mmHg to 1.24 atm at a constant temperature of 25°C. Assume ideal behavior.

**20.114** Iron melts at 1535°C and its enthalpy of fusion is 13.8 kJ/mol. Calculate the entropy of fusion per mole of iron.

**20.115** Calculate the entropy change for the vaporization of 25.0 g of hexane,  $C_6H_{14}$ , at its boiling point of 68.8°C. The enthalpy of vaporization of hexane is 28.8 kJ/mol.

**20.116** Calculate the entropy change of a 235 g sample of copper that is heated at constant pressure from 32.0°C to 125°C.  $C_{p,m}$  for copper = 24.5 J/mol·K.

**20.117** The temperature of a 625 g piece of granite is increased from 18.0°C to 60.0°C. What is its change in entropy? The specific heat capacity of granite is 0.790 J/g·K.

**20.118** The boiling point of chloroform,  $CHCl_3$ , is 61.2°C. Use Trouton's rule to estimate the enthalpy of vaporization of chloroform.

## Concepts and Skills to Review Before You Study This Chapter

- › redox terminology (Section 4.5)
- › activity series of the metals (Section 4.6)
- › trends in ionization energy (Section 8.3) and electronegativity (Section 9.5)
- › free energy, work, and equilibrium (Sections 20.3 and 20.4)
- ›  $Q$  vs.  $K$  (Section 17.4) and  $\Delta G$  vs.  $\Delta G^\circ$  (Section 20.4)

**T**hermodynamics has countless applications. Some are probably at your fingertips right now: a laptop computer or tablet, MP3 player, or smart phone. These are a few of the objects you use every day that rely on a major field in applied thermodynamics called **electrochemistry**, the study of the relationship between chemical change and electrical work. This field relies on **electrochemical cells**, systems that incorporate a redox reaction to produce or utilize electrical energy.

**IN THIS CHAPTER . . .** We examine the essential features of electrochemical cells and quantify the relationship between free energy and electrical work.

- › We review oxidation-reduction (redox) reactions and describe a method for balancing redox reactions that take place in electrochemical cells.
- › We highlight key differences between the two types of electrochemical cells.
- › We focus on voltaic cells, which *release* free energy to do electrical work, and see how they operate as a combination of two half-cells.
- › We calculate the voltage, the cell's electrical potential, which is the sum of the voltages of the half-cells.
- › We use half-cell voltages to determine the relative strengths of redox couples and to write spontaneous redox equations.
- › We examine the interdependence of the standard free energy change, the standard cell potential, and the equilibrium constant.
- › We follow the change in voltage as a voltaic cell operates.
- › We see how differences in concentration between the solutions in the half-cells can be harnessed to generate electricity.
- › We analyze the makeup and operation of some major types of batteries.
- › We describe the problem of corrosion, which has key similarities to the operation of voltaic cells.
- › We examine electrolytic cells, which *absorb* free energy from an external source to do electrical work. We predict the products that form under different conditions and quantify the relation between charge and amount of substance.
- › We explore the redox system that generates energy in living cells.

## 21.1 REDOX REACTIONS AND ELECTROCHEMICAL CELLS

To begin, we review the oxidation-reduction process that we covered in Chapter 4 and describe the *half-reaction method* of balancing redox reactions. Then we see how redox reactions are used in the two types of electrochemical cells.

### A Quick Review of Oxidation-Reduction Concepts

All electrochemical processes involve the *movement of electrons from one chemical species to another* in an oxidation-reduction (redox) reaction. In any redox process:

- *Oxidation* is the loss of electrons, and *reduction* is the gain of electrons. Oxidation and reduction occur *simultaneously*.

- The *oxidizing agent* does the oxidizing by *taking electrons* from the substance being oxidized. The *reducing agent* does the reducing by *giving electrons* to the substance being reduced. Therefore:

*The oxidizing agent is reduced, and the reducing agent is oxidized.*

- The oxidized substance ends up with a *higher* (more positive or less negative) oxidation number (O.N.), and the reduced substance ends up with a *lower* (less positive or more negative) O.N.
- The total number of electrons gained by the atoms/ions of the oxidizing agent equals the total number lost by the atoms/ions of the reducing agent.

Figure 21.1 presents these ideas for the aqueous reaction between zinc metal and  $H^+$  from a strong acid. Be sure you can identify the oxidation and reduction parts of a redox process. You may want to review the full discussion in Section 4.5.

**Figure 21.1** A summary of redox terminology, as applied to the reaction of zinc with hydrogen ion.

## Half-Reaction Method for Balancing Redox Reactions

In Chapter 4, you learned how to determine the oxidation number of each element in a compound, how to identify oxidizing and reducing agents, and how to decide if a chemical change is a redox reaction. Now, let's see how to balance redox reactions. The **half-reaction method** is especially useful for studying electrochemistry:

- It *divides the overall redox reaction* into oxidation and reduction *half-reactions*, which, as you'll see, reflect their actual physical separation in electrochemical cells.
- It applies well to reactions in acidic or basic solution, which are common in cells.
- It (usually) does *not* require assigning O.N.s. (In cases where the half-reactions are not obvious, we assign O.N.s to determine which atoms undergo a change and write half-reactions with the species that contain those atoms.)

**Steps in the Half-Reaction Method** The balancing process begins with a “skeleton” ionic reaction that consists of only species that are oxidized and reduced. Here are the steps in the half-reaction method:

- Step 1.* Divide the skeleton reaction into two half-reactions. Each half-reaction contains the oxidized and reduced forms of one of the species: *if the oxidized form of a species is on the left side, the reduced form must be on the right, and vice versa.*
- Step 2.* Balance the atoms and charges in each half-reaction.
  - Atoms are balanced *in this order*: atoms other than O and H, then O, then H.
  - Charge is balanced by *adding electrons* ( $e^-$ ) *to the left side in the reduction half-reaction* because the reactant gains them and *to the right side in the oxidation half-reaction* because the reactant loses them.
- Step 3.* If necessary, multiply one or both half-reactions by an integer so that
 
$$\text{number of } e^- \text{ gained in reduction} = \text{number of } e^- \text{ lost in oxidation}$$
- Step 4.* Add the balanced half-reactions, and include states of matter.
- Step 5.* Check that the atoms and charges are balanced.

Let's balance a redox reaction that occurs in acidic solution and then see how to balance one in basic solution in Sample Problem 21.1.

**Balancing Redox Reactions in Acidic Solution** For a reaction in acidic solution,  $\text{H}_2\text{O}$  molecules and  $\text{H}^+$  ions are present for the balancing. We've usually used  $\text{H}_3\text{O}^+$  to represent the proton in water, but we use  $\text{H}^+$  in this chapter because it makes the balancing simpler. To make that point, we'll also balance this first reaction with  $\text{H}_3\text{O}^+$  to show that the only difference is in the number of water molecules.

The reaction between dichromate ion and iodide ion to form chromium(III) ion and solid iodine occurs in acidic solution (*see photo*). The skeleton ionic reaction is

*Step 1. Divide the reaction into half-reactions.* Each half-reaction contains the oxidized and reduced forms of one species:

*Step 2. Balance atoms and charges in each half-reaction.* We use  $\text{H}_2\text{O}$  to balance O,  $\text{H}^+$  to balance H, and  $e^-$  to balance charges.

For the  $\text{Cr}_2\text{O}_7^{2-}/\text{Cr}^{3+}$  half-reaction:

a. *Balance atoms other than O and H.* We balance the two Cr in  $\text{Cr}_2\text{O}_7^{2-}$  on the left with a coefficient of 2 on the right:

b. *Balance O atoms by adding  $\text{H}_2\text{O}$  molecules.* Each  $\text{H}_2\text{O}$  has one O atom, so we add seven  $\text{H}_2\text{O}$  on the right to balance the seven O in  $\text{Cr}_2\text{O}_7^{2-}$ :

c. *Balance H atoms by adding  $\text{H}^+$  ions.* Each  $\text{H}_2\text{O}$  contains two H, and we added seven  $\text{H}_2\text{O}$ , so we add 14  $\text{H}^+$  ions on the left:

d. *Balance charge by adding electrons.* Each  $\text{H}^+$  ion has a 1+ charge, and 14  $\text{H}^+$  plus the 2- of  $\text{Cr}_2\text{O}_7^{2-}$  gives 12+ on the left. Two  $\text{Cr}^{3+}$  give 6+ on the right. There is an excess of 6+ on the left, so we add six  $e^-$  on the left:

This half-reaction is balanced. We note that

- it is the *reduction* because electrons appear on the *left*, as a *reactant*;
- $\text{Cr}_2\text{O}_7^{2-}$  gains electrons (is reduced), so  $\text{Cr}_2\text{O}_7^{2-}$  is the *oxidizing agent*;
- the O.N. of Cr decreases from +6 on the left to +3 on the right.

For the  $\text{I}^-/\text{I}_2$  half-reaction:

a. *Balance atoms other than O and H.* Two I atoms on the right require a coefficient of 2 on the left:

b. *Balance O atoms with  $\text{H}_2\text{O}$ .* Not needed; there are no O atoms.

c. *Balance H atoms with  $\text{H}^+$ .* Not needed; there are no H atoms.

d. *Balance charge with  $e^-$ .* To balance the 2- on the left, we add two  $e^-$  on the right:

This half-reaction is balanced. We see that

- it is the *oxidation* because electrons appear on the *right*, as a *product*;
- the reactant  $\text{I}^-$  loses electrons (is oxidized), so  $\text{I}^-$  is the *reducing agent*;
- the O.N. of I increases from -1 to 0.

*Step 3. Multiply each half-reaction, if necessary, by an integer so that the number of  $e^-$  lost in the oxidation equals the number of  $e^-$  gained in the reduction.* Two  $e^-$  are

Dichromate ion (*left*) and iodide ion (*center*) form chromium(III) ion and solid iodine (*right*).

Source: © McGraw-Hill Education/Stephen Frisch, photographer

lost in the oxidation and six  $e^-$  are gained in the reduction, so we multiply the oxidation by 3:

*Step 4. Add the half-reactions, canceling species that appear on both sides, and include states of matter. In this example, only the electrons cancel:*

*Step 5. Check that atoms and charges balance:*

**Using  $H_3O^+$ , Instead of  $H^+$ , to Balance H** Now let's see what happens if we use  $H_3O^+$  to supply H atoms, instead of  $H^+$ . In step 2 for the reduction half-reaction, balancing Cr atoms and balancing O atoms with  $H_2O$  are the same as before, so we have

Now we use  $H_3O^+$  to balance H atoms. Because each  $H_3O^+$  is an  $H^+$  bonded to an  $H_2O$ , we balance the 14 H on the right with 14  $H_3O^+$  on the left and immediately add 14 more  $H_2O$  on the right:

Taking the sum of the  $H_2O$  molecules on the right gives

None of this affects the redox change, so balancing the charge still requires six  $e^-$  on the left, and we obtain the balanced reduction half-reaction:

Adding the balanced oxidation half-reaction gives the balanced redox equation:

Note that, as mentioned earlier, the only difference is the number of  $H_2O$  molecules: 21  $H_2O$  instead of 7  $H_2O$ . So, even though this approach uses  $H_3O^+$ , which shows more accurately how  $H^+$  exists, only the number of water molecules changes and the balancing involves more steps. Therefore, we'll continue to use  $H^+$  to balance H atoms in these equations.

**Balancing Redox Reactions in Basic Solution** In acidic solution,  $H_2O$  molecules and  $H^+$  ions are available to balance a redox reaction, but in basic solution,  $H_2O$  molecules and  $OH^-$  ions are available.

We need only one additional step to balance a redox reaction that takes place in basic solution. It appears after we balance the half-reactions *as if they occur in acidic solution* and are combined (step 4). At this point, *we add one  $OH^-$  to both sides of the equation for every  $H^+$  present*. (This step is labeled "4 Basic" in Sample Problem 21.1.) The  $OH^-$  ions added on the side with  $H^+$  ions combine with them to form  $H_2O$  molecules, while the  $OH^-$  on the other side remain in the equation, and then excess  $H_2O$  is canceled.

### Student Hot Spot

Student data indicate that you may struggle with balancing redox reactions in basic solution. Access the Smartbook to view additional Learning Resources on this topic.

### SAMPLE PROBLEM 21.1

### Balancing a Redox Reaction in Basic Solution

**Problem** Permanganate ion reacts in basic solution with oxalate ion to form carbonate ion and solid manganese dioxide. Balance the skeleton ionic equation for the reaction between  $NaMnO_4$  and  $Na_2C_2O_4$  in basic solution:

**Plan** We follow the numbered steps as described in text, and proceed through step 4 as if this reaction occurs in acidic solution. Then, we add the appropriate number of  $OH^-$  ions and cancel excess  $H_2O$  molecules (see "4 Basic").

**Solution**

1. Divide into half-reactions.

2. Balance.

- a. Atoms other than O and H.
- 
- Not needed.

- a. Atoms other than O and H,
- 
- $\text{C}_2\text{O}_4^{2-} \longrightarrow 2\text{CO}_3^{2-}$

- b. O atoms with
- $\text{H}_2\text{O}$
- ,
- 
- $\text{MnO}_4^- \longrightarrow \text{MnO}_2 + 2\text{H}_2\text{O}$

- b. O atoms with
- $\text{H}_2\text{O}$
- ,
- 
- $2\text{H}_2\text{O} + \text{C}_2\text{O}_4^{2-} \longrightarrow 2\text{CO}_3^{2-}$

- c. H atoms with
- $\text{H}^+$
- ,
- 
- $4\text{H}^+ + \text{MnO}_4^- \longrightarrow \text{MnO}_2 + 2\text{H}_2\text{O}$

- c. H atoms with
- $\text{H}^+$
- ,
- 
- $2\text{H}_2\text{O} + \text{C}_2\text{O}_4^{2-} \longrightarrow 2\text{CO}_3^{2-} + 4\text{H}^+$

- d. Charge with
- $e^-$
- ,
- 
- $3e^- + 4\text{H}^+ + \text{MnO}_4^- \longrightarrow \text{MnO}_2 + 2\text{H}_2\text{O}$
- 
- [reduction]

- d. Charge with
- $e^-$
- ,
- 
- $2\text{H}_2\text{O} + \text{C}_2\text{O}_4^{2-} \longrightarrow 2\text{CO}_3^{2-} + 4\text{H}^+ + 2e^-$
- 
- [oxidation]

3. Multiply each half-reaction, if necessary, by some integer to make
- $e^-$
- lost equal
- $e^-$
- gained.

4. Add half-reactions, and cancel species appearing on both sides.

The six  $e^-$  cancel, eight  $\text{H}^+$  cancel to leave four  $\text{H}^+$  on the right, and four  $\text{H}_2\text{O}$  cancel to leave two  $\text{H}_2\text{O}$  on the left:

- 4 Basic.**
- Add
- $\text{OH}^-$
- to both sides to neutralize the
- $\text{H}^+$
- present, and cancel excess
- $\text{H}_2\text{O}$
- .

Adding four  $\text{OH}^-$  to both sides forms four  $\text{H}_2\text{O}$  on the right. Two of those cancel the two  $\text{H}_2\text{O}$  on the left and leave two  $\text{H}_2\text{O}$  on the right:

Including states of matter gives the final balanced equation:

5. Check that atoms and charges balance.

**Comment** As a final step, let's see how to obtain the balanced *molecular* equation for this reaction. We note the amount (mol) of each anion in the balanced ionic equation and add the correct amount (mol) of spectator ions (in this case,  $\text{Na}^+$ , as given in the problem statement) to obtain neutral compounds. The balanced molecular equation is

**FOLLOW-UP PROBLEMS**

*Brief Solutions to all Follow-up Problems appear at the end of the chapter.*

**21.1A** Write a balanced molecular equation for the reaction between  $\text{KMnO}_4$  and  $\text{KI}$  in basic solution. The skeleton ionic reaction is

**21.1B** Write a balanced molecular equation for the reaction between chromium(III) hydroxide and sodium iodate in basic solution. The skeleton ionic reaction is

**SOME SIMILAR PROBLEMS** 21.12–21.19

## An Overview of Electrochemical Cells

The fundamental difference between the two types of electrochemical cells is based on whether the overall redox reaction in the cell is spontaneous (free energy is released) or nonspontaneous (free energy is absorbed):

1. A **voltaic cell** (also called a **galvanic cell**) uses a *spontaneous* redox reaction ( $\Delta G < 0$ ) to generate electrical energy. In the cell reaction, some of the difference in free energy between higher energy reactants and lower energy products is converted into electrical energy, which operates the load—flashlight, MP3 player, car starter motor, and so forth. Thus, *the system does work on the surroundings (load)*. All batteries contain voltaic cells.
2. An **electrolytic cell** uses electrical energy to drive a *nonspontaneous* redox reaction ( $\Delta G > 0$ ). In the cell reaction, an external power source supplies free energy to convert lower energy reactants into higher energy products. Thus, *the surroundings (power supply) do work on the system*. Electroplating and the recovery of metals from ores utilize electrolytic cells.

The two types of cell have several similarities. Two **electrodes**, which conduct the electricity between cell and surroundings, are dipped into an **electrolyte**, a mixture of ions (usually in aqueous solution) that are involved in the reaction or that carry the charge (Figure 21.2). An electrode is identified as either **anode** or **cathode** depending on the half-reaction that takes place there:

- *The oxidation half-reaction occurs at the anode.* Electrons lost by the substance being oxidized (reducing agent) *leave the oxidation half-cell at the anode.*
- *The reduction half-reaction occurs at the cathode.* Electrons gained by the substance being reduced (oxidizing agent) *enter the reduction half-cell at the cathode.* ◀

Note that, for reasons we discuss shortly, *the relative charges of the electrodes are opposite in sign in the two types of cell.*

### Which Half-Reaction Occurs at Which Electrode?

Here are some memory aids to help you remember which half-reaction occurs at which electrode:

1. The words *anode* and *oxidation* start with vowels; the words *cathode* and *reduction* start with consonants.
2. Alphabetically, the A in anode comes before the C in cathode, and the O in oxidation comes before the R in reduction.
3. Look at the first syllables and use your imagination:  
ANode, OXidation; REDuction,  
CAThode  $\Rightarrow$  AN OX and a RED CAT

**Figure 21.2** General characteristics of (A) voltaic cells and (B) electrolytic cells.

## › Summary of Section 21.1

- › An oxidation-reduction (redox) reaction involves the transfer of electrons from a reducing agent to an oxidizing agent.
- › The half-reaction method of balancing divides the overall reaction into half-reactions that are balanced separately and then recombined.
- › There are two types of electrochemical cells. In a voltaic cell, a spontaneous reaction generates electricity and does work on the surroundings. In an electrolytic cell, the surroundings supply electricity that does work to drive a nonspontaneous reaction.
- › In both types of cell, two electrodes dip into electrolyte solutions; oxidation occurs at the anode, and reduction occurs at the cathode.

## 21.2 VOLTAIC CELLS: USING SPONTANEOUS REACTIONS TO GENERATE ELECTRICAL ENERGY

When you put a strip of zinc metal in a solution of  $\text{Cu}^{2+}$  ion, the blue color of the solution fades and a brown-black crust of copper metal forms on the zinc strip (Figure 21.3). During this spontaneous reaction,  $\text{Cu}^{2+}$  ion (blue in color) is reduced to Cu metal, while Zn metal is oxidized to  $\text{Zn}^{2+}$  ion (colorless). The overall reaction consists of two half-reactions:

Let's examine this spontaneous reaction as the basis of a voltaic cell.

**Figure 21.3** The spontaneous reaction between zinc and copper(II) ion. When zinc metal is placed in a solution of  $\text{Cu}^{2+}$  ion (left), zinc is oxidized to  $\text{Zn}^{2+}$ , and  $\text{Cu}^{2+}$  is reduced to copper metal (right). (The very finely divided Cu appears black.)

## Construction and Operation of a Voltaic Cell

Electrons are being transferred in the  $\text{Zn}/\text{Cu}^{2+}$  reaction, but the system does not generate electrical energy because the oxidizing agent ( $\text{Cu}^{2+}$ ) and the reducing agent ( $\text{Zn}$ ) are in the *same* beaker. If, however, we physically separate the half-reactions and connect them by an external circuit, the electrons lost by the zinc produce an electric current as they travel through the circuit toward the copper ions that gain them.

**Basis of the Voltaic Cell: Separation of Half-Reactions** In any voltaic cell, the components of each half-reaction are placed in a separate container, or **half-cell**, which consists of one electrode dipping into an electrolyte solution (Figure 21.4A). The two half-cells are joined by the external circuit, and a voltmeter measures the voltage generated. A switch (not shown) closes (completes) or opens (breaks) the circuit. Here are some key points about the half-cells of the  $\text{Zn}/\text{Cu}^{2+}$  voltaic cell:

1. **Oxidation half-cell (anode compartment, always shown on the left).** The anode compartment consists of a bar of zinc (the anode) immersed in a  $\text{Zn}^{2+}$  electrolyte (such as aqueous zinc sulfate,  $\text{ZnSO}_4$ ). Zinc metal is the reactant in the oxidation half-reaction, and the bar loses electrons *and* conducts them *out* of this half-cell.
2. **Reduction half-cell (cathode compartment, always shown on the right).** The cathode compartment consists of a bar of copper (the cathode) immersed in a  $\text{Cu}^{2+}$  electrolyte [such as aqueous copper(II) sulfate,  $\text{CuSO}_4$ ]. Copper is the product in the reduction half-reaction, and the bar conducts electrons *into* its half-cell, where  $\text{Cu}^{2+}$  is reduced.

**Figure 21.4** A voltaic cell based on the zinc-copper reaction. **A**, In the anode half-cell (oxidation; *left*), two electrons from a Zn atom move through the Zn bar as the  $\text{Zn}^{2+}$  ion enters the solution. In the cathode half-cell (reduction; *right*), the electrons reduce  $\text{Cu}^{2+}$  ions to Cu atoms. **B**, After several hours, the Zn anode weighs less and the Cu cathode weighs more.

Source: B: © McGraw-Hill Education/Stephen Frisch, photographer

**Charges of the Electrodes** The charges of the electrodes are determined by the *source of electrons* and the *direction of electron flow* through the circuit. In this cell, Zn atoms are oxidized at the anode to  $\text{Zn}^{2+}$  ions and are the source of electrons. The  $\text{Zn}^{2+}$  ions enter the half-cell's electrolyte, while the electrons move through the bar and into the wire. *The electrons flow left to right* through the wire to the cathode, where  $\text{Cu}^{2+}$  ions in this half-cell's electrolyte are reduced to Cu atoms. As the cell operates, electrons are continuously generated at the anode and consumed at the cathode. Therefore, the anode has an excess of electrons and the cathode has a deficit of electrons: *in any voltaic cell, the anode is negative relative to the cathode.*

**Completing the Circuit with a Salt Bridge** A cell cannot operate unless the circuit is complete. The oxidation half-cell initially contains a neutral solution of  $\text{Zn}^{2+}$  and  $\text{SO}_4^{2-}$  ions, but as Zn atoms in the bar lose electrons, the  $\text{Zn}^{2+}$  ions that form enter the solution and would give it a net positive charge. Similarly, in the reduction half-cell, the initial neutral solution of  $\text{Cu}^{2+}$  and  $\text{SO}_4^{2-}$  ions would develop a net negative charge as  $\text{Cu}^{2+}$  ions leave the solution and form Cu atoms. If allowed to occur, such a charge imbalance between the half-cells would stop cell operation.

This situation is avoided by use of a **salt bridge**. It joins the half-cells and acts like a “liquid wire,” allowing ions to flow through both compartments and complete the circuit while keeping the electrolyte solutions neutral. The salt bridge is an inverted U tube containing nonreacting ions, such as  $\text{Na}^+$  and  $\text{SO}_4^{2-}$ , dissolved in a gel, which does not flow out of the tube but allows ions to diffuse into or out of the half-cells:

- *Maintaining a neutral reduction half-cell (right; cathode compartment).* As  $\text{Cu}^{2+}$  ions change to Cu atoms,  $\text{Na}^+$  ions move from the salt bridge into the electrolyte solution (and some  $\text{SO}_4^{2-}$  ions move from the solution into the salt bridge).
- *Maintaining a neutral oxidation half-cell (left; anode compartment).* As Zn atoms change to  $\text{Zn}^{2+}$  ions,  $\text{SO}_4^{2-}$  ions move from the salt bridge into the electrolyte solution (and some  $\text{Zn}^{2+}$  ions move from the solution into the salt bridge).

Thus, the wire and the salt bridge complete the circuit:

- *Electrons move left to right* through the wire.
- *Anions move right to left* through the salt bridge into the anode half-cell.
- *Cations move left to right* through the salt bridge into the cathode half-cell.

**Active vs. Inactive Electrodes** The electrodes in the Zn/ $\text{Cu}^{2+}$  cell are *active* because the metals themselves are components of the half-reactions. As the cell operates, the mass of the zinc bar gradually decreases, as the  $[\text{Zn}^{2+}]$  in the anode half-cell increases. At the same time, the mass of the copper bar increases as the  $[\text{Cu}^{2+}]$  in the cathode half-cell decreases and the ions form atoms that “plate out” on the electrode (Figure 21.4B).

In many cases, however, there are no reaction components that can be physically used as an electrode, so *inactive* electrodes are used. Most commonly, inactive electrodes are rods of *graphite* or *platinum*. In a voltaic cell based on the following half-reactions, for instance, the reacting species cannot be made into electrodes:

Each half-cell consists of an inactive electrode immersed in an electrolyte that contains *all the reactant species involved in that half-reaction* (Figure 21.5):

- In the *anode half-cell*,  $\text{I}^-$  ions are oxidized to solid  $\text{I}_2$ , and the released electrons flow into the graphite (C) electrode and through the wire.
- From the wire, the electrons enter the graphite electrode in the *cathode half-cell* and reduce  $\text{MnO}_4^-$  ions to  $\text{Mn}^{2+}$  ions. (A  $\text{KNO}_3$  salt bridge is used.)

**Figure 21.5** A voltaic cell using inactive electrodes.

**Diagram of a Voltaic Cell** As Figures 21.4A and 21.5 show, there are certain consistent features in the *diagram* of any voltaic cell:

- Components of the half-cells include electrode materials, electrolyte ions, and other species involved in the reaction.
- Electrode name (anode or cathode) and charge are shown. By convention, the anode compartment appears *on the left*.
- Each half-reaction and the overall cell reaction are given.
- Direction of electron flow in the external circuit is from left to right.
- Nature of ions and direction of ion flow in the salt bridge are shown, with cations moving right and anions moving left.

## Notation for a Voltaic Cell

A useful shorthand notation describes the components of a voltaic cell. The notation for the Zn/Cu<sup>2+</sup> cell is

Key parts of the notation are as follows:

- The components of the anode compartment (oxidation half-cell) are written *to the left* of the components of the cathode compartment (reduction half-cell).
- A double vertical line indicates the half-cells are physically separated.
- A single vertical line represents a phase boundary. For example, Zn(s) | Zn<sup>2+</sup>(aq) indicates that *solid* Zn is a *different* phase from *aqueous* Zn<sup>2+</sup>.
- A comma separates the half-cell components that are in the *same* phase. For example, the notation for the voltaic cell shown in Figure 21.5 is

That is, in the cathode compartment, MnO<sub>4</sub><sup>-</sup>, H<sup>+</sup>, and Mn<sup>2+</sup> ions are in an aqueous solution with solid graphite immersed in it.

- If needed, the concentrations of dissolved components are given in parentheses; for example, if the concentrations of Zn<sup>2+</sup> and Cu<sup>2+</sup> are 1 M, we write

- Half-cell components usually appear in the same order as in the half-reaction, and electrodes appear at the far left (anode) and far right (cathode) of the notation.
- Ions in the salt bridge are not part of the reaction so they are not in the notation.

### SAMPLE PROBLEM 21.2

### Describing a Voltaic Cell with a Diagram and Notation

**Problem** Draw a diagram, show balanced half-cell and cell equations, and write the notation for a voltaic cell that consists of one half-cell with a Cr bar in a Cr(NO<sub>3</sub>)<sub>3</sub> solution, another half-cell with an Ag bar in an AgNO<sub>3</sub> solution, and a KNO<sub>3</sub> salt bridge. Measurement indicates that the Cr electrode is negative relative to the Ag electrode.

**Plan** From the given contents of the half-cells, we write the half-reactions. To determine which is the anode compartment (oxidation) and which is the cathode (reduction), we note the relative electrode charges (which are based on the direction of the spontaneous redox reaction). Electrons are released into the anode during oxidation, so it has a negative charge. We are told that Cr is negative, so it is the anode and Ag is the cathode.

**Solution** Writing the balanced half-reactions. The Ag half-reaction consumes e<sup>-</sup>:

The Cr half-reaction releases e<sup>-</sup>:

Writing the balanced overall cell equation. We triple the reduction half-reaction to balance e<sup>-</sup> and combine the half-reactions:

Determining direction of electron and ion flow. The released  $e^-$  in the Cr electrode (negative) flow through the external circuit to the Ag electrode (positive). As  $Cr^{3+}$  ions enter the anode electrolyte,  $NO_3^-$  ions enter from the salt bridge to maintain neutrality. As  $Ag^+$  ions leave the cathode electrolyte and plate out on the Ag electrode,  $K^+$  ions enter from the salt bridge to maintain neutrality. The cell diagram is shown in the margin. Writing the cell notation with the oxidation components on the left and the reduction components on the right:

**Check** Always be sure that the half-reactions and the cell reaction are balanced, the half-cells contain *all* components of the half-reactions, and the electron and ion flow are shown. You should be able to write the half-reactions from the cell notation as a check.

**Comment** The diagram of a voltaic cell relies on the *direction of the spontaneous reaction* to give the oxidation (anode; negative) and reduction (cathode; positive) half-reactions.

### FOLLOW-UP PROBLEMS

**21.2A** In one half-cell of a voltaic cell, a graphite rod dips into an acidic solution of  $K_2Cr_2O_7$  and  $Cr(NO_3)_3$ ; in the other half-cell, a tin bar dips into a  $Sn(NO_3)_2$  solution. A  $KNO_3$  salt bridge joins the half-cells. The tin electrode is negative relative to the graphite. Diagram the cell, and write the balanced half-cell and cell equations and the cell notation.

**21.2B** In one half-cell of a voltaic cell, a graphite rod dips into an acidic solution of  $KClO_3$  and  $KCl$ ; in the other half-cell, a nickel bar dips into a  $Ni(NO_3)_2$  solution. A  $KNO_3$  salt bridge joins the half-cells, and the graphite is positive relative to the nickel. Diagram the cell, and write balanced half-cell and cell equations and the cell notation.

**SOME SIMILAR PROBLEMS** 21.29–21.34

## Why Does a Voltaic Cell Work?

What principles explain *how* the  $Zn/Cu^{2+}$  cell reaction takes place and *why* electrons flow in the direction they do? Let's examine what is happening when the switch is open and no reaction is occurring. In each half-cell, the metal electrode is in equilibrium with the metal ions in the electrolyte and the electrons within the metal:

Given the direction of the overall spontaneous reaction, Zn gives up its electrons more easily than Cu does; that is, Zn is a stronger reducing agent. Therefore, the equilibrium position of the Zn half-reaction lies farther to the right. We can think of the electrons in the Zn electrode as being subject to a greater "pressure" than those in the Cu electrode, a greater potential energy (referred to as *electrical potential*) ready to "push" them through the circuit. Close the switch, and electrons flow from the Zn to the Cu electrode to equalize this difference in electrical potential. The flow disturbs the equilibrium at each electrode. The Zn half-reaction shifts to the right to restore the electrons flowing out, and the Cu half-reaction shifts to the left to remove the electrons flowing in. Thus, *the spontaneous reaction occurs as a result of the different abilities of these metals to give up their electrons.* >

### > Summary of Section 21.2

- > A voltaic cell consists of oxidation (anode) and reduction (cathode) half-cells, connected by a wire to conduct electrons and a salt bridge to maintain charge neutrality.
- > Electrons move from the anode (left) to the cathode (right), while cations move from the salt bridge into the cathode half-cell and anions move from the salt bridge into the anode half-cell.
- > The cell notation shows the species and their phases in each half-cell, as well as the direction of current flow.
- > A voltaic cell operates because species in the two half-cells differ in the tendency to lose electrons (strength as a reducing agent).

### Electron Flow and Water Flow

Consider this analogy between electron "pressure" and water pressure. A U tube (cell) is separated into two arms (two half-cells) by a stopcock (switch), and the two arms contain water at different heights (the half-cells have different electrical potentials). Open the stopcock (close the switch), and the different heights (potential difference) become equal as water flows (electrons flow and current is generated).

## 21.3 CELL POTENTIAL: OUTPUT OF A VOLTAIC CELL

A voltaic cell converts the free energy change of a spontaneous reaction into the kinetic energy of electrons moving through an external circuit (electrical energy). This electrical energy is proportional to the *difference in electrical potential between the two electrodes*, which is called the **cell potential** ( $E_{\text{cell}}$ ), the **voltage** of the cell, or the **electromotive force (emf)**.

Electrons flow spontaneously from the negative to the positive electrode, that is, toward the electrode with the more positive electrical potential. Thus, when the cell operates *spontaneously*, there is a *positive* cell potential:

$$E_{\text{cell}} > 0 \text{ for a spontaneous process} \quad (21.1)$$

- $E_{\text{cell}} > 0$  for a spontaneous reaction. The more positive  $E_{\text{cell}}$  is, the more work the cell can do, and the farther the reaction proceeds to the right as written.
- $E_{\text{cell}} < 0$  for a *nonspontaneous* cell reaction.
- $E_{\text{cell}} = 0$  when the reaction has reached equilibrium, so the cell can do no more work. (We return to these ideas in Section 21.4.)

### Standard Cell Potential ( $E_{\text{cell}}^{\circ}$ )

The SI unit of electrical potential is the **volt (V)**, and the SI unit of electrical charge is the **coulomb (C)**. By definition, if two electrodes differ by 1 volt of electrical potential, 1 joule of energy is released (that is, 1 joule of work can be done) for each coulomb of charge that moves between the electrodes. That is,

$$1 \text{ V} = 1 \text{ J/C} \quad (21.2)$$

Table 21.1 lists the voltages of some commercial and natural voltaic cells.

The *measured* cell potential is affected by changes in concentration as the reaction proceeds and by energy losses from heating the cell and external circuit. Therefore, as with other thermodynamic quantities, to compare potentials of different cells, we obtain a **standard cell potential** ( $E_{\text{cell}}^{\circ}$ ), which is measured at a specified temperature (usually 298 K) with no current flowing\* and *all components in their standard states*: 1 atm for gases, 1 M for solutions, the pure solid for electrodes. For example, the zinc-copper cell produces 1.10 V when it operates at 298 K with  $[\text{Zn}^{2+}] = [\text{Cu}^{2+}] = 1 \text{ M}$  (Figure 21.6):

**Standard Electrode (Half-Cell) Potential ( $E_{\text{half-cell}}^{\circ}$ )** Just as each half-reaction makes up part of the overall reaction, each half-cell (electrode) potential makes up a part of the overall cell potential. The **standard electrode potential** ( $E_{\text{half-cell}}^{\circ}$ ) (or **standard half-cell potential**) is the electrical potential of a given half-reaction (half-cell compartment) with all components in their standard states.

By convention (and as reference tables list them), *standard electrode potentials refer to the half-reactions written as reductions*. (A list of these potentials, like that in Appendix D, is called an *emf series* or a *table of standard electrode potentials*.) For example, for the zinc-copper reaction, both the zinc half-reaction ( $E_{\text{zinc}}^{\circ}$ , anode compartment) and the copper half-reaction ( $E_{\text{copper}}^{\circ}$ , cathode compartment) are written as reductions:

But, since the overall cell reaction involves the *oxidation* of zinc, not the *reduction* of  $\text{Zn}^{2+}$ , we can show what is actually occurring by reversing the zinc (anode) half-reaction:

\*The tiny current required to operate modern digital voltmeters makes a negligible difference in the value of  $E_{\text{cell}}^{\circ}$

**Table 21.1** Voltages of Some Voltaic Cells

Voltaic Cell	Voltage (V)
Common alkaline flashlight battery	1.5
Lead-acid car battery (6 cells $\approx$ 12 V)	2.1
Calculator battery (mercury)	1.3
Lithium-ion laptop battery	3.7
Electric eel ( $\sim$ 5000 cells in 6-ft eel = 750 V)	0.15
Nerve of giant squid (across cell membrane)	0.070

**Figure 21.6** Measuring the standard cell potential of a zinc-copper cell.

Source: © Richard Megna/Fundamental Photographs, NYC

**Calculating  $E_{\text{cell}}^{\circ}$  from  $E_{\text{half-cell}}^{\circ}$**  The overall redox reaction for the zinc-copper cell is the sum of its half-reactions:

Because electrons flow spontaneously from the negative to the positive electrode, the copper electrode (cathode) has a more positive  $E_{\text{half-cell}}^{\circ}$  than the zinc electrode (anode). As you'll see shortly, to obtain a positive  $E_{\text{cell}}^{\circ}$  for this spontaneous redox reaction, we subtract  $E_{\text{zinc}}^{\circ}$  from  $E_{\text{copper}}^{\circ}$ :

$$E_{\text{cell}}^{\circ} = E_{\text{copper}}^{\circ} - E_{\text{zinc}}^{\circ}$$

We can generalize this result for any voltaic cell: *the standard cell potential is the standard electrode potential of the cathode (reduction) half-cell minus the standard electrode potential of the anode (oxidation) half-cell:*

$$E_{\text{cell}}^{\circ} = E_{\text{cathode(reduction)}}^{\circ} - E_{\text{anode(oxidation)}}^{\circ} \quad (21.3)$$

For a *spontaneous* reaction at standard conditions, this calculation gives  $E_{\text{cell}}^{\circ} > 0$ .

### SAMPLE PROBLEM 21.3

### Using $E_{\text{half-cell}}^{\circ}$ Values to Find $E_{\text{cell}}^{\circ}$

**Problem** Balance the following skeleton ionic reaction, and calculate  $E_{\text{cell}}^{\circ}$  to decide whether the reaction is spontaneous:

**Plan** We balance the skeleton reaction (see Sample Problem 21.1). Then, we look up the  $E_{\text{half-cell}}^{\circ}$  values in Appendix D and use Equation 21.3 to find  $E_{\text{cell}}^{\circ}$ . If  $E_{\text{cell}}^{\circ}$  is positive, the reaction is spontaneous.

**Solution** Balancing the skeleton reaction:

Using  $E_{\text{half-cell}}^{\circ}$  values to find  $E_{\text{cell}}^{\circ}$ :

$$\begin{aligned} E_{\text{cell}}^{\circ} &= E_{\text{cathode(reduction)}}^{\circ} - E_{\text{anode(oxidation)}}^{\circ} = 1.07 \text{ V} - 1.51 \text{ V} \\ &= -0.44 \text{ V; not spontaneous} \end{aligned}$$

**Check** Rounding to check the calculation:  $1.00 \text{ V} - 1.50 \text{ V} = -0.50 \text{ V}$ . A negative  $E_{\text{cell}}^{\circ}$  indicates a nonspontaneous reaction.

### FOLLOW-UP PROBLEMS

**21.3A** Balance the following skeleton ionic reaction, and calculate  $E_{\text{cell}}^{\circ}$  to decide whether the reaction is spontaneous:

**21.3B** Balance the following skeleton ionic reaction, and calculate  $E_{\text{cell}}^{\circ}$  to decide whether the reaction is spontaneous:

**SOME SIMILAR PROBLEMS** 21.42–21.45

**Determining  $E_{\text{half-cell}}^{\circ}$  with the Standard Hydrogen Electrode** To compare half-cell potentials, we need to know the portion of  $E_{\text{cell}}^{\circ}$  contributed by each half-cell. But, how can we find individual half-cell potentials if we can measure only the potential of the overall cell? We can do so because half-cell potentials, such as  $E_{\text{zinc}}^{\circ}$  and  $E_{\text{copper}}^{\circ}$ , are measured *relative* to a standard reference half-cell, *which has a standard electrode potential defined as zero* ( $E_{\text{reference}}^{\circ} \equiv 0.00 \text{ V}$ ). To find an unknown standard electrode potential ( $E_{\text{unknown}}^{\circ}$ ), we construct a voltaic cell consisting of this reference half-cell and the unknown half-cell. Since  $E_{\text{reference}}^{\circ}$  is zero, the overall  $E_{\text{cell}}^{\circ}$  gives  $E_{\text{unknown}}^{\circ}$ .

The **standard reference half-cell** is a **standard hydrogen electrode**, which consists of a platinum electrode that has  $\text{H}_2$  gas at 1 atm bubbling through it and is immersed in 1  $M$  strong acid, which means 1  $M$   $\text{H}^+(\text{aq})$  [or  $\text{H}_3\text{O}^+(\text{aq})$ ]. Thus, the reference half-reaction is

Depending on the unknown half-cell, the reference half-cell can be the anode or the cathode:

- When  $\text{H}_2$  is oxidized, the reference half-cell is the anode, and so *reduction* occurs at the unknown half-cell:

$$E_{\text{cell}}^\circ = E_{\text{cathode}}^\circ - E_{\text{anode}}^\circ = E_{\text{unknown}}^\circ - E_{\text{reference}}^\circ = E_{\text{unknown}}^\circ - 0.00 \text{ V} = E_{\text{unknown}}^\circ$$

- When  $\text{H}^+$  is reduced, the reference half-cell is the cathode, and so *oxidation* occurs at the unknown half-cell:

$$E_{\text{cell}}^\circ = E_{\text{cathode}}^\circ - E_{\text{anode}}^\circ = E_{\text{reference}}^\circ - E_{\text{unknown}}^\circ = 0.00 \text{ V} - E_{\text{unknown}}^\circ = -E_{\text{unknown}}^\circ$$

Figure 21.7 shows a voltaic cell that has the  $\text{Zn}/\text{Zn}^{2+}$  half-reaction in one compartment and the  $\text{H}^+/\text{H}_2$  (or  $\text{H}_3\text{O}^+/\text{H}_2$ ) half-reaction in the other. The zinc electrode is negative relative to the hydrogen electrode, so we know that the zinc is being oxidized and is the anode. The measured  $E_{\text{cell}}^\circ$  is +0.76 V (the reaction is spontaneous), and we use this value to find the unknown standard electrode potential,  $E_{\text{zinc}}^\circ$ :

Solving for  $E_{\text{zinc}}^\circ$ , the standard half-cell potential for  $\text{Zn}^{2+} + 2e^- \rightarrow \text{Zn}$ , gives

$$E_{\text{zinc}}^\circ = E_{\text{reference}}^\circ - E_{\text{cell}}^\circ = 0.00 \text{ V} - 0.76 \text{ V} = -0.76 \text{ V}$$

Now we can return to the zinc-copper cell and use the measured  $E_{\text{cell}}^\circ$  (1.10 V) and the value we just found for  $E_{\text{zinc}}^\circ$  to calculate  $E_{\text{copper}}^\circ$ :

$$E_{\text{cell}}^\circ = E_{\text{cathode}}^\circ - E_{\text{anode}}^\circ = E_{\text{copper}}^\circ - E_{\text{zinc}}^\circ$$

and, 
$$E_{\text{copper}}^\circ = E_{\text{cell}}^\circ + E_{\text{zinc}}^\circ = 1.10 \text{ V} + (-0.76 \text{ V}) = 0.34 \text{ V}$$

By continuing this process of constructing cells with one known and one unknown electrode potential, we find other standard electrode potentials.

**Figure 21.7** Determining an unknown  $E_{\text{half-cell}}^\circ$  with the standard reference (hydrogen) electrode. The magnified view of the hydrogen half-reaction (*right*) shows two  $\text{H}_3\text{O}^+$  ions being reduced to two  $\text{H}_2\text{O}$  molecules and an  $\text{H}_2$  molecule, which enters the  $\text{H}_2$  bubble.

## SAMPLE PROBLEM 21.4

Calculating an Unknown  $E^\circ_{\text{half-cell}}$  from  $E^\circ_{\text{cell}}$ 

**Problem** A voltaic cell houses the reaction between aqueous bromine and zinc metal:

Calculate  $E^\circ_{\text{bromine}}$ , given  $E^\circ_{\text{zinc}} = -0.76 \text{ V}$ .

**Plan**  $E^\circ_{\text{cell}}$  is positive, so the reaction is spontaneous as written. By dividing the reaction into half-reactions, we see that  $\text{Br}_2$  is reduced and Zn is oxidized; thus, the zinc half-cell contains the anode. We use Equation 21.3 and the known  $E^\circ_{\text{zinc}}$  to find  $E^\circ_{\text{unknown}}$  ( $E^\circ_{\text{bromine}}$ ).

**Solution** Dividing the reaction into half-reactions:

Calculating  $E^\circ_{\text{bromine}}$ :

$$\begin{aligned} E^\circ_{\text{cell}} &= E^\circ_{\text{cathode}} - E^\circ_{\text{anode}} = E^\circ_{\text{bromine}} - E^\circ_{\text{zinc}} \\ E^\circ_{\text{bromine}} &= E^\circ_{\text{cell}} + E^\circ_{\text{zinc}} = 1.83 \text{ V} + (-0.76 \text{ V}) = 1.07 \text{ V} \end{aligned}$$

**Check** A good check is to make sure that calculating  $E^\circ_{\text{bromine}} - E^\circ_{\text{zinc}}$  gives  $E^\circ_{\text{cell}}$ :  
 $1.07 \text{ V} - (-0.76 \text{ V}) = 1.83 \text{ V}$ .

**Comment** Keep in mind that, whichever half-cell potential is unknown, reduction is the cathode half-reaction and oxidation is the anode half-reaction. *Always* subtract  $E^\circ_{\text{anode}}$  from  $E^\circ_{\text{cathode}}$  to get  $E^\circ_{\text{cell}}$ . (We use  $E^\circ_{\text{bromine}}$  in Follow-up Problem 21.4A.)

## FOLLOW-UP PROBLEMS

**21.4A** A voltaic cell based on the reaction between aqueous  $\text{Br}_2$  and vanadium(III) ions has  $E^\circ_{\text{cell}} = 0.73 \text{ V}$ :

What is  $E^\circ_{\text{vanadium}}$ , the standard electrode potential for the reduction of  $\text{VO}^{2+}$  to  $\text{V}^{3+}$ ?

**21.4B** A voltaic cell based on the reaction between vanadium(III) and nitrate ions has  $E^\circ_{\text{cell}} = 0.62 \text{ V}$ :

Use the value for  $E^\circ_{\text{vanadium}}$  you obtained in Follow-up Problem 21.4A to find  $E^\circ_{\text{nitrate}}$ , the standard electrode potential for the reduction of  $\text{NO}_3^-$  to  $\text{NO}$ .

**SOME SIMILAR PROBLEMS** 21.38 and 21.39

## Relative Strengths of Oxidizing and Reducing Agents

We learn the relative strengths of oxidizing and reducing agents from measuring cell potentials. Three oxidizing agents we just discussed are  $\text{Cu}^{2+}$ ,  $\text{H}^+$ , and  $\text{Zn}^{2+}$ . Let's rank, from high (*top*) to low (*bottom*), their relative oxidizing strengths by writing each half-reaction as a reduction (gain of electrons), with its corresponding standard electrode potential:

The more positive the  $E^\circ$  value, the more readily the reaction (as written) occurs; thus,  $\text{Cu}^{2+}$  gains two  $e^-$  more readily than  $\text{H}^+$ , which gains them more readily than  $\text{Zn}^{2+}$ :

- Strength as an oxidizing agent *decreases* top to bottom:  $\text{Cu}^{2+} > \text{H}^+ > \text{Zn}^{2+}$ .
- Strength as a reducing agent *increases* top to bottom:  $\text{Zn} > \text{H}_2 > \text{Cu}$ .

By continuing this process with other half-cells, we create a list of reduction half-reactions in *decreasing* order of standard electrode potential (from most positive

Table 21.2

Selected Standard Electrode Potentials (298 K)

Half-Reaction	$E^\circ_{\text{half-cell}}$ (V)
$\text{F}_2(g) + 2e^- \rightleftharpoons 2\text{F}^-(aq)$	+2.87
$\text{Cl}_2(g) + 2e^- \rightleftharpoons 2\text{Cl}^-(aq)$	+1.36
$\text{MnO}_2(s) + 4\text{H}^+(aq) + 2e^- \rightleftharpoons \text{Mn}^{2+}(aq) + 2\text{H}_2\text{O}(l)$	+1.23
$\text{NO}_3^-(aq) + 4\text{H}^+(aq) + 3e^- \rightleftharpoons \text{NO}(g) + 2\text{H}_2\text{O}(l)$	+0.96
$\text{Ag}^+(aq) + e^- \rightleftharpoons \text{Ag}(s)$	+0.80
$\text{Fe}^{3+}(aq) + e^- \rightleftharpoons \text{Fe}^{2+}(aq)$	+0.77
$\text{O}_2(g) + 2\text{H}_2\text{O}(l) + 4e^- \rightleftharpoons 4\text{OH}^-(aq)$	+0.40
$\text{Cu}^{2+}(aq) + 2e^- \rightleftharpoons \text{Cu}(s)$	+0.34
$2\text{H}^+(aq) + 2e^- \rightleftharpoons \text{H}_2(g)$	0.00
$\text{N}_2(g) + 5\text{H}^+(aq) + 4e^- \rightleftharpoons \text{N}_2\text{H}_5^+(aq)$	-0.23
$\text{Fe}^{2+}(aq) + 2e^- \rightleftharpoons \text{Fe}(s)$	-0.44
$\text{Zn}^{2+}(aq) + 2e^- \rightleftharpoons \text{Zn}(s)$	-0.76
$2\text{H}_2\text{O}(l) + 2e^- \rightleftharpoons \text{H}_2(g) + 2\text{OH}^-(aq)$	-0.83
$\text{Na}^+(aq) + e^- \rightleftharpoons \text{Na}(s)$	-2.71
$\text{Li}^+(aq) + e^- \rightleftharpoons \text{Li}(s)$	-3.05

to most negative), as in Appendix D; a few examples are presented in Table 21.2. There are several key points to keep in mind:

- All values are relative to the standard hydrogen (reference) electrode.
- Since the half-reactions are written as *reductions*, *reactants are oxidizing agents* and *products are reducing agents*.
- The more positive the  $E^\circ_{\text{half-cell}}$ , the more readily the half-reaction occurs, as written.
- Half-reactions are shown with an equilibrium arrow because each can occur as a reduction (at the cathode) or an oxidation (at the anode), depending on the  $E^\circ_{\text{half-cell}}$  of the other half-reaction. In calculations, *always* use  $E^\circ_{\text{half-cell}}$  for the half-reaction *written as a reduction*.
- As Appendix D (or Table 21.2) is arranged, the strength of the oxidizing agent (reactant) *increases going up (bottom to top)*, and the strength of the reducing agent (product) *increases going down (top to bottom)*.

Thus,  $\text{F}_2(g)$  is the strongest oxidizing agent (has the largest positive  $E^\circ$ ), which means  $\text{F}^-(aq)$  is the weakest reducing agent. Similarly,  $\text{Li}^+(aq)$  is the weakest oxidizing agent (has the most negative  $E^\circ$ ), which means  $\text{Li}(s)$  is the strongest reducing agent: a *strong oxidizing agent forms a weak reducing agent*, and vice versa. Rely on your knowledge of the redox behavior of the elements (see Section 8.4) if you forget the ranking in the table:

- $\text{F}_2$  is very electronegative and occurs naturally as  $\text{F}^-$ , so it is easily reduced (gains electrons) and must be a strong oxidizing agent (high, positive  $E^\circ$ ).
- Li metal has a low ionization energy and occurs naturally as  $\text{Li}^+$ , so it is easily oxidized (loses electrons) and must be a strong reducing agent (low, negative  $E^\circ$ ).

### Using $E^\circ_{\text{half-cell}}$ Values to Write Spontaneous Redox Reactions

Every redox reaction is the sum of two half-reactions, so there is a reducing agent and an oxidizing agent on each side. In the zinc-copper reaction, for instance, Zn and Cu are the reducing agents, and  $\text{Cu}^{2+}$  and  $\text{Zn}^{2+}$  are the oxidizing agents. The stronger oxidizing and reducing agents react spontaneously to form the weaker oxidizing and reducing agents:

Based on the order of the  $E^\circ$  values in Appendix D, and as we just saw for the  $\text{Cu}^{2+}/\text{Cu}$ ,  $\text{H}^+/\text{H}_2$ , and  $\text{Zn}^{2+}/\text{Zn}$  redox pairs (or redox *couples*), *the stronger oxidizing agent (species on the left) has a half-reaction with a larger (more positive or less negative)  $E^\circ$  value, and the stronger reducing agent (species on the right) has a half-reaction with a smaller (less positive or more negative)  $E^\circ$  value.* Therefore, we can use Appendix D to choose a redox reaction for constructing a voltaic cell.

**Writing a Spontaneous Reaction with Appendix D** A spontaneous reaction ( $E^\circ_{\text{cell}} > 0$ ) will occur between an oxidizing agent and any reducing agent that lies *below* it in the list of standard electrode potentials in Appendix D. In other words:

- For a spontaneous reaction to occur, the half-reaction higher in the list proceeds at the cathode as written, and the half-reaction lower in the list proceeds at the anode in reverse.

This pairing ensures that the stronger oxidizing agent (higher on the left) and stronger reducing agent (lower on the right) will be the reactants. For example, two half-reactions in the order they appear in Appendix D are

Here are the steps we follow to write a spontaneous reaction between these reactants:

- Reverse the nickel half-reaction (it is lower in the list):

Note, however, that *we do not reverse the sign of  $E^\circ_{\text{half-cell}}$*  because the arithmetic operation of subtraction in Equation 21.3 (cathode – anode) will do that.

- Make sure that  $e^-$  lost equals  $e^-$  gained; if not, multiply one or both half-reactions by a coefficient to accomplish this. In this case, both  $e^-$  lost and  $e^-$  gained are  $2e^-$ , so we skip this step.
- Add the half-reactions to get the balanced equation:

- Apply Equation 21.3 to find  $E^\circ_{\text{cell}}$ :

$$E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}} = E^\circ_{\text{chlorine}} - E^\circ_{\text{nickel}} = 1.36 \text{ V} - (-0.25 \text{ V}) = 1.61 \text{ V}$$

**Writing a Spontaneous Reaction Without Appendix D** Even when a list like Appendix D is not available, we can write a spontaneous redox reaction from a given pair of half-reactions. For example, here are two half-reactions:

Two steps are required:

1. Reverse one of the half-reactions into an oxidation step so that the difference of the electrode potentials (cathode *minus* anode) gives a *positive*  $E^\circ_{\text{cell}}$ . (Remember that when we reverse the half-reaction, we do *not* reverse the sign of  $E^\circ_{\text{half-cell}}$ .)
2. Multiply by one or more coefficients to make  $e^-$  lost equal  $e^-$  gained, add the rearranged half-reactions to get a balanced overall equation, and cancel species common to both sides.

We want the reactants to be the stronger oxidizing and reducing agents:

- The larger (more positive)  $E^\circ$  value for the silver half-reaction means that  $\text{Ag}^+$  is a stronger oxidizing agent (gains electrons more readily) than  $\text{Sn}^{2+}$ .
- The smaller (more negative)  $E^\circ$  value for the tin half-reaction means that Sn is a stronger reducing agent (loses electrons more readily) than Ag.

For step 1, we reverse the tin half-reaction (but *not* the sign of  $E_{\text{tin}}^{\circ}$ ):

because when we subtract  $E_{\text{half-cell}}^{\circ}$  of the tin half-reaction (anode, oxidation) from  $E_{\text{half-cell}}^{\circ}$  of the silver half-reaction (cathode, reduction), we get a positive  $E_{\text{cell}}^{\circ}$ :

$$0.80 \text{ V} - (-0.14 \text{ V}) = 0.94 \text{ V}$$

For step 2, the number of electrons lost in the oxidation must equal the number gained in the reduction, so we double the silver (reduction) half-reaction. Adding the half-reactions and applying Equation 21.3 gives

A very important point to note is that, when we double the coefficients of the silver half-reaction, we do *not* double its  $E_{\text{half-cell}}^{\circ}$ . Changing the coefficients of a half-reaction does *not* change its  $E_{\text{half-cell}}^{\circ}$  because a standard electrode potential is an intensive property, one that does *not* depend on the amount of substance. Let's see why. The potential is the *ratio* of energy to charge. When we change the coefficients to change the amounts, the energy *and* the charge change proportionately, so their ratio stays the same. (Similarly, density does not change with the amount of substance because the mass *and* the volume change proportionately.)

### Student Hot Spot

Student data indicate that you may struggle with using electrode potentials to determine spontaneity. Access the Smartbook to view additional Learning Resources on this topic.

#### SAMPLE PROBLEM 21.5

#### Writing Spontaneous Redox Reactions and Ranking Oxidizing and Reducing Agents by Strength

**Problem** (a) Combine pairs of the balanced half-reactions (1), (2), and (3) into three spontaneous reactions A, B, and C, and calculate  $E_{\text{cell}}^{\circ}$  for each. (b) Rank the relative strengths of the oxidizing and reducing agents.

**Plan** (a) To write spontaneous redox reactions, we combine the possible pairs of half-reactions: (1) and (2) give reaction A, (1) and (3) give B, and (2) and (3) give C. They are all written as reductions, so the oxidizing agents appear as reactants and the reducing agents appear as products. For each pair, we reverse the half-reaction that has the smaller (less positive or more negative)  $E^{\circ}$  value to an oxidation (without changing the sign of  $E^{\circ}$ ) to obtain a positive  $E_{\text{cell}}^{\circ}$ . We make  $e^{-}$  lost equal  $e^{-}$  gained (without changing the  $E^{\circ}$  value), add the half-reactions together, and then apply Equation 21.3 to find  $E_{\text{cell}}^{\circ}$ . (b) Because each reaction is spontaneous as written, the stronger oxidizing and reducing agents are the reactants. To obtain the overall ranking, we first rank the relative strengths within each equation and then compare them.

**Solution** (a) Combining half-reactions (1) and (2) gives equation A. The  $E^{\circ}$  value for half-reaction (1) is larger (more positive) than that for (2), so we reverse (2) to obtain a positive  $E_{\text{cell}}^{\circ}$ :

To make  $e^{-}$  lost equal  $e^{-}$  gained, we multiply (1) by four and the reversed (2) by three; then add half-reactions and cancel appropriate numbers of common species ( $\text{H}^{+}$  and  $e^{-}$ ):

$$E_{\text{cell}}^{\circ} = 0.96 \text{ V} - (-0.23 \text{ V}) = 1.19 \text{ V}$$

Combining half-reactions (1) and (3) gives equation B. Half-reaction (1) has a smaller  $E^\circ$ , so it is reversed:

We multiply reversed (1) by two and (3) by three, then add and cancel:

$$E_{\text{cell}}^\circ = 1.23 \text{ V} - 0.96 \text{ V} = 0.27 \text{ V}$$

Combining half-reactions (2) and (3) gives equation C. Half-reaction (2) has a smaller  $E^\circ$ , so it is reversed:

We multiply reaction (3) by two, add the half-reactions, and cancel:

$$E_{\text{cell}}^\circ = 1.23 \text{ V} - (-0.23 \text{ V}) = 1.46 \text{ V}$$

**(b)** Ranking the oxidizing and reducing agents within each reaction:

Equation A    Oxidizing agents:  $\text{NO}_3^- > \text{N}_2$     Reducing agents:  $\text{N}_2\text{H}_5^+ > \text{NO}$

Equation B    Oxidizing agents:  $\text{MnO}_2 > \text{NO}_3^-$     Reducing agents:  $\text{NO} > \text{Mn}^{2+}$

Equation C    Oxidizing agents:  $\text{MnO}_2 > \text{N}_2$     Reducing agents:  $\text{N}_2\text{H}_5^+ > \text{Mn}^{2+}$

Determining the overall ranking of oxidizing and reducing agents. Comparing the relative strengths from the three balanced equations gives

Oxidizing agents:  $\text{MnO}_2 > \text{NO}_3^- > \text{N}_2$

Reducing agents:  $\text{N}_2\text{H}_5^+ > \text{NO} > \text{Mn}^{2+}$

**Check** As always, check that atoms and charges balance on both sides of each equation. A good way to check the ranking and equations is to list the given half-reactions in order of decreasing  $E^\circ$  value:

Then the oxidizing agents (reactants) decrease in strength going down the list, so the reducing agents (products) decrease in strength going up. Moreover, each of the equations for the spontaneous reactions (A, B, and C) should combine a reactant with a product that is lower down on this list.

### FOLLOW-UP PROBLEMS

**21.5A** (a) Combine pairs of the balanced half-reactions (1), (2), and (3) into three spontaneous reactions A, B, and C, and calculate  $E_{\text{cell}}^\circ$  for each:

**(b)** Rank the relative strengths of the oxidizing and reducing agents.

**21.5B** Is the following reaction spontaneous as written (see Appendix D)?

If not, write the equation for the spontaneous reaction, calculate  $E_{\text{cell}}^\circ$ , and rank the three species of iron in order of decreasing strength as reducing agents.

**SOME SIMILAR PROBLEMS** 21.46–21.49

## Explaining the Activity Series of the Metals

In Chapter 4, we discussed the activity series of the metals (see Figure 4.24), which ranks metals by their ability to “displace” one another from aqueous solution. Now you’ll see *why* this displacement occurs, as well as why many, but not all, metals react with acid to form  $H_2$ , and why a few metals form  $H_2$  even in water.

1. *Metals that can displace  $H_2$  from acid.* The standard hydrogen half-reaction represents the reduction of  $H^+$  ions from an acid to  $H_2$ :

To see which metals reduce  $H^+$  (referred to as “displacing  $H_2$ ”) from acids, choose a metal, write its half-reaction as an oxidation, combine this half-reaction with the hydrogen half-reaction, and see if  $E^\circ_{\text{cell}}$  is positive. We find that the metals Li through Pb, those that lie *below* the standard hydrogen (reference) half-reaction in Appendix D, give a positive  $E^\circ_{\text{cell}}$  when reducing  $H^+$ . Iron, for example, reduces  $H^+$  from an acid to  $H_2$ :

The lower the metal in the list, the stronger it is as a reducing agent; therefore, *if  $E^\circ_{\text{cell}}$  for the reduction of  $H^+$  is more positive with metal A than with metal B, metal A is a stronger reducing agent than metal B and a more **active** metal.*

2. *Metals that cannot displace  $H_2$  from acid.* For metals that are *above* the standard hydrogen (reference) half-reaction,  $E^\circ_{\text{cell}}$  is negative when we reverse the metal half-reaction, so the reaction does not occur. For example, the coinage metals—copper, silver, and gold, which are in Group 1B(11)—are not strong enough reducing agents to reduce  $H^+$  from acids:

The *higher* the metal in the list, the *more negative* is its  $E^\circ_{\text{cell}}$  for the reduction of  $H^+$  to  $H_2$ , the *lower* is its reducing strength, and the *less active* it is. Thus, gold is less active than silver, which is less active than copper.

3. *Metals that can displace  $H_2$  from water.* Metals active enough to reduce  $H_2O$  lie *below* that half-reaction:

For example, consider the reaction of sodium in water (with the  $Na^+/Na$  half-reaction reversed and doubled):

The alkali metals [Group 1A(1)] and the larger alkaline earth metals [Group 2A(2)] can reduce water (displace  $H_2$  from  $H_2O$ ). Figure 21.8 shows calcium reducing  $H_2O$  to  $H_2$ .

4. *Metals that displace other metals from solution.* We can also predict whether one metal can reduce the aqueous ion of another metal. Any metal that is lower in the list in Appendix D can reduce the ion of a metal that is higher up, and thus displace that metal from solution. For example, zinc can displace iron from solution:

This particular reaction has tremendous economic importance in protecting iron from rusting, as we’ll discuss in Section 21.6.

Oxidation half-reaction  
 $\text{Ca}(s) \longrightarrow \text{Ca}^{2+}(aq) + 2e^-$

Reduction half-reaction  
 $2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq)$

Overall (cell) reaction  
 $\text{Ca}(s) + 2H_2O(l) \longrightarrow \text{Ca(OH)}_2(aq) + H_2(g)$

**Figure 21.8** The reaction of calcium in water.

A common incident involving the reducing power of metals occurs when you bite down with a filled tooth on a scrap of aluminum foil left on a piece of food. The foil acts as an active anode ( $E_{\text{aluminum}}^{\circ} = -1.66 \text{ V}$ ), saliva as the electrolyte, and the filling (usually a silver/tin/mercury alloy) as an inactive cathode at which  $\text{O}_2$  is reduced ( $E_{\text{O}_2}^{\circ} = 1.23 \text{ V}$ ) to water. The circuit between the foil and the filling creates a current that is sensed as pain by the nerve of the tooth (Figure 21.9).

Figure 21.9 A dental “voltaic cell.”

### › Summary of Section 21.3

- › The output of a voltaic cell is the cell potential ( $E_{\text{cell}}$ ), measured in volts ( $1 \text{ V} = 1 \text{ J/C}$ ).
- › With all substances in their standard states, the output is the standard cell potential ( $E_{\text{cell}}^{\circ}$ ).
- ›  $E_{\text{cell}}^{\circ} > 0$  for a spontaneous reaction at standard-state conditions.
- › By convention, a standard electrode potential ( $E_{\text{half-cell}}^{\circ}$ ) refers to the *reduction* half-reaction.
- ›  $E_{\text{cell}}^{\circ}$  equals  $E_{\text{half-cell}}^{\circ}$  of the cathode *minus*  $E_{\text{half-cell}}^{\circ}$  of the anode.
- › A standard hydrogen (reference) electrode ( $E_{\text{reference}}^{\circ} = 0 \text{ V}$ ) is used to measure  $E_{\text{half-cell}}^{\circ}$  values and to rank oxidizing (or reducing) agents.
- › Spontaneous redox reactions combine stronger oxidizing and reducing agents to form weaker reducing and oxidizing agents, respectively.
- › A metal can reduce another species ( $\text{H}^+$ ,  $\text{H}_2\text{O}$ , or an ion of another metal) if  $E_{\text{cell}}^{\circ}$  for the overall reaction is positive.

## 21.4 FREE ENERGY AND ELECTRICAL WORK

Following up on our discussion in Chapter 20, in this section, we examine the relationship of useful work, free energy, and the equilibrium constant in the context of electrochemical cells and see the effect of concentration on cell potential.

### Standard Cell Potential and the Equilibrium Constant

The signs of  $\Delta G$  and  $E_{\text{cell}}$  are *opposite* for a spontaneous reaction: a *negative* free energy change ( $\Delta G < 0$ ; Section 20.3) and a *positive* cell potential ( $E_{\text{cell}} > 0$ ). These two indicators of spontaneity are proportional to each other:

$$\Delta G \propto -E_{\text{cell}}$$

Let's determine this proportionality constant. The electrical work done ( $w$ , in joules) is the product of the potential ( $E_{\text{cell}}$ , in volts) and the charge that flows (in coulombs). Since  $E_{\text{cell}}$  is measured with no current flowing and, thus, no energy lost as heat, it is the maximum voltage possible, and, thus, determines the maximum work possible ( $w_{\text{max}}$ ).<sup>\*</sup> Work done *by* the cell *on* the surroundings has a negative sign:

$$w_{\text{max}} = -E_{\text{cell}} \times \text{charge}$$

The maximum work done *on* the surroundings is equal to  $\Delta G$  (Equation 20.9):

$$w_{\text{max}} = \Delta G = -E_{\text{cell}} \times \text{charge}$$

The charge that flows through the cell equals the amount (mol) of electrons transferred ( $n$ ) times the charge of 1 mol of electrons (which has the symbol  $F$ ):

$$\text{Charge} = \text{amount (mol) of } e^{-} \times \frac{\text{charge}}{\text{mol } e^{-}} \quad \text{or} \quad \text{charge} = nF$$

The charge of 1 mol of electrons is the **Faraday constant** ( $F$ ), named for Michael Faraday, the 19<sup>th</sup>-century British scientist who pioneered the study of electrochemistry:

$$F = \frac{96,485 \text{ C}}{\text{mol } e^{-}}$$

<sup>\*</sup>Recall from Chapter 20 that only a reversible process can do maximum work. For no current to flow and the process to be reversible,  $E_{\text{cell}}$  must be opposed by an equal potential in the measuring circuit: if the opposing potential is infinitesimally smaller, the cell reaction goes forward; if it is infinitesimally larger, the reaction goes backward.

**Figure 21.10** The interrelationship of  $\Delta G^\circ$ ,  $E^\circ_{\text{cell}}$ , and  $K$ . **A**, Any one parameter can be used to find the other two. **B**, The signs of  $\Delta G^\circ$ ,  $K$ , and  $E^\circ_{\text{cell}}$  determine reaction direction.

Reaction Parameters at the Standard State			Reaction at standard-state conditions
$\Delta G^\circ$	$K$	$E^\circ_{\text{cell}}$	
<0	>1	>0	Spontaneous
0	1	0	At equilibrium
>0	<1	<0	Nonspontaneous

Because  $1 \text{ V} = 1 \text{ J/C}$ , we have  $1 \text{ C} = 1 \text{ J/V}$ , and

$$F = 9.65 \times 10^4 \frac{\text{J}}{\text{V} \cdot \text{mol e}^-} \quad (3 \text{ sf}) \quad (21.4)$$

Substituting for charge, the proportionality constant is  $nF$ :

$$\Delta G = -nFE_{\text{cell}} \quad (21.5)$$

And, when all components are in their standard states, we have

$$\Delta G^\circ = -nFE^\circ_{\text{cell}} \quad (21.6)$$

Using this relationship, we can relate the standard cell potential to the equilibrium constant of the redox reaction. Recall from Equation 20.12 that

$$\Delta G^\circ = -RT \ln K$$

Substituting for  $\Delta G^\circ$  from Equation 21.6 gives

$$-nFE^\circ_{\text{cell}} = -RT \ln K$$

Solving for  $E^\circ_{\text{cell}}$  gives

$$E^\circ_{\text{cell}} = \frac{RT}{nF} \ln K \quad (21.7)$$

Figure 21.10 summarizes the interconnections among the standard free energy change, the equilibrium constant, and the standard cell potential. In Chapter 20, we determined  $K$  from  $\Delta G^\circ$ , which we found either from  $\Delta H^\circ$  and  $\Delta S^\circ$  values or from  $\Delta G^\circ_f$  values. Now, for redox reactions, we have a direct *experimental* method for determining  $K$  and  $\Delta G^\circ$ : measure  $E^\circ_{\text{cell}}$ .

In calculations, we adjust Equation 21.7 as follows:

- Substitute  $8.314 \text{ J}/(\text{mol rxn} \cdot \text{K})$  for the constant  $R$ .
- Substitute  $9.65 \times 10^4 \text{ J}/(\text{V} \cdot \text{mol e}^-)$  for the constant  $F$ .
- Substitute  $298.15 \text{ K}$  for  $T$ , keeping in mind that the cell can run at other temperatures.
- Multiply by 2.303 to convert the natural logarithm to the common (base-10) logarithm. This conversion shows that a *10-fold change in  $K$  makes  $E^\circ_{\text{cell}}$  change by 1*.

Thus, when  $n$  moles of  $\text{e}^-$  are transferred per mole of reaction, based on the balanced equation, we have

$$E^\circ_{\text{cell}} = \frac{RT}{nF} \ln K = 2.303 \times \frac{8.314 \frac{\text{J}}{\text{mol rxn} \cdot \text{K}} \times 298.15 \text{ K}}{n \frac{\text{mol e}^-}{\text{mol rxn}} \left( 9.65 \times 10^4 \frac{\text{J}}{\text{V} \cdot \text{mol e}^-} \right)} \log K$$

And this becomes

$$E^\circ_{\text{cell}} = \frac{0.0592 \text{ V}}{n} \log K \quad \text{or} \quad \log K = \frac{nE^\circ_{\text{cell}}}{0.0592 \text{ V}} \quad (\text{at } 298.15 \text{ K}) \quad (21.8)$$

## SAMPLE PROBLEM 21.6

Calculating  $K$  and  $\Delta G^\circ$  from  $E^\circ_{\text{cell}}$ 

**Problem** Silver occurs in trace amounts in some ores of lead, and lead can displace silver from solution:

As a consequence, silver is a valuable byproduct in the industrial extraction of lead from its ores. Calculate  $K$  and  $\Delta G^\circ$  at 298.15 K for this reaction.

**Plan** We divide the spontaneous redox reaction into half-reactions and use values from Appendix D to calculate  $E^\circ_{\text{cell}}$ . Then, we substitute this result into Equations 21.7 and 21.8 to find  $K$  and into Equation 21.6 to find  $\Delta G^\circ$ .

**Solution** Writing the half-reactions with their  $E^\circ$  values:

Calculating  $E^\circ_{\text{cell}}$ : We double half-reaction (1) to obtain a gain of 2 mol of electrons, reverse (2) since this is the oxidation half-reaction, add the half-reactions, and subtract  $E^\circ_{\text{lead}}$  from  $E^\circ_{\text{silver}}$ :

Calculating  $K$  with Equations 21.7 and 21.8: The adjusted half-reactions show that 2 mol of  $e^-$  are transferred per mole of reaction as written, so  $n = 2$ . Then, performing the substitutions for  $R$  and  $F$  that we just discussed, changing to common logarithms, and running the cell at 25°C (298.15 K), we have

$$E^\circ_{\text{cell}} = \frac{RT}{nF} \ln K = \frac{0.0592 \text{ V}}{n} \log K = \frac{0.0592 \text{ V}}{2} \log K = 0.93 \text{ V}$$

$$\text{So,} \quad \log K = \frac{0.93 \text{ V} \times 2}{0.0592 \text{ V}} = 31.42 \quad \text{and} \quad K = 10^{31.42} = 2.6 \times 10^{31}$$

Calculating  $\Delta G^\circ$  (Equation 21.6):

$$\Delta G^\circ = -nFE^\circ_{\text{cell}} = -\frac{2 \text{ mol } e^-}{\text{mol rxn}} \times \frac{96.5 \text{ kJ}}{\text{V} \cdot \text{mol } e^-} \times 0.93 \text{ V} = -1.8 \times 10^2 \text{ kJ/mol rxn}$$

**Check** The three variables are consistent with the reaction being spontaneous at standard-state conditions:  $E^\circ_{\text{cell}} > 0$ ,  $\Delta G^\circ < 0$ , and  $K > 1$ . Be sure to round and check the order of magnitude: to find  $\Delta G^\circ$ , for instance,  $\Delta G^\circ \approx -2 \times 100 \times 1 = -200$ , so the overall math seems right. Another check would be to obtain  $\Delta G^\circ$  directly from its relation with  $K$ :

$$\begin{aligned} \Delta G^\circ &= -RT \ln K = -8.314 \text{ J/mol rxn} \cdot \text{K} \times 298.15 \text{ K} \times \ln (2.6 \times 10^{31}) \\ &= -1.8 \times 10^5 \text{ J/mol rxn} = -1.8 \times 10^2 \text{ kJ/mol rxn} \end{aligned}$$

## FOLLOW-UP PROBLEMS

**21.6A** Calculate  $K$  and  $\Delta G^\circ$  for the following reaction at 298.15 K:

**21.6B** When cadmium metal reduces  $\text{Cu}^{2+}$  in solution,  $\text{Cd}^{2+}$  forms in addition to copper metal. Given that  $\Delta G^\circ = -143 \text{ kJ/mol rxn}$ , calculate  $K$  at 25°C. What is  $E^\circ_{\text{cell}}$  of a voltaic cell that uses this reaction?

**SOME SIMILAR PROBLEMS** 21.56–21.67

## The Effect of Concentration on Cell Potential

So far, we've considered cells at standard-state conditions, but most cells don't start with those concentrations, and even if they did, concentrations change as the cell operates. Moreover, in all batteries, reactant concentrations are far from the standard state.

To determine  $E_{\text{cell}}$ , the cell potential under *nonstandard* conditions, we'll derive an expression for the relation between  $E_{\text{cell}}$  and concentration based on the relation between  $\Delta G$  and concentration. Recall from Chapter 20 (Equation 20.13) that

$$\Delta G = \Delta G^\circ + RT \ln Q$$

$\Delta G$  is related to  $E_{\text{cell}}$ , and  $\Delta G^\circ$  is related to  $E_{\text{cell}}^\circ$  (Equations 21.5 and 21.6); substituting, we get

$$-nFE_{\text{cell}} = -nFE_{\text{cell}}^\circ + RT \ln Q$$

Dividing both sides by  $-nF$ , we obtain the equation developed by the great German chemist Walther Hermann Nernst when he was only 25 years old. (In his career, which culminated in the 1920 Nobel Prize in chemistry, he also formulated the third law of thermodynamics and established the concept of the solubility product.) The **Nernst equation** says that  $E_{\text{cell}}$  depends on  $E_{\text{cell}}^\circ$  and a term for the potential at any ratio of concentrations:

$$E_{\text{cell}} = E_{\text{cell}}^\circ - \frac{RT}{nF} \ln Q \quad (21.9)$$

How do changes in  $Q$  affect cell potential? From Equation 21.9, we see that

- When  $Q < 1$  and thus [reactant] > [product],  $\ln Q < 0$ , so  $E_{\text{cell}} > E_{\text{cell}}^\circ$ .
- When  $Q = 1$  and thus [reactant] = [product],  $\ln Q = 0$ , so  $E_{\text{cell}} = E_{\text{cell}}^\circ$ .
- When  $Q > 1$  and thus [reactant] < [product],  $\ln Q > 0$ , so  $E_{\text{cell}} < E_{\text{cell}}^\circ$ .

As before, to obtain a form we can use for calculations, we substitute known values of  $R$  and  $F$ , operate the cell at 298.15 K, and convert to the common (base-10) logarithm:

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^\circ - \frac{RT}{nF} \ln Q \\ &= E_{\text{cell}}^\circ - 2.303 \times \frac{8.314 \frac{\text{J}}{\text{mol} \cdot \text{rxn} \cdot \text{K}} \times 298.15 \text{ K}}{n \frac{\text{mol} \cdot \text{e}^-}{\text{mol} \cdot \text{rxn}} \left( 9.65 \times 10^4 \frac{\text{J}}{\text{V} \cdot \text{mol} \cdot \text{e}^-} \right)} \log Q \end{aligned}$$

We obtain

$$E_{\text{cell}} = E_{\text{cell}}^\circ - \frac{0.0592 \text{ V}}{n} \log Q \quad (\text{at } 298.15 \text{ K}) \quad (21.10)$$

Remember that the expression for  $Q$  contains only those species with concentrations (and/or pressures) that can vary; thus, pure liquids do not appear nor do solids, even when they are the electrodes. For example, in the reaction between cadmium and silver ion, the Cd and Ag electrodes do not appear in the expression for  $Q$ :

### Student Hot Spot

Student data indicate that you may struggle with calculations involving the Nernst equation. Access the Smartbook to view additional Learning Resources on this topic.

### SAMPLE PROBLEM 21.7

### Using the Nernst Equation to Calculate $E_{\text{cell}}$

**Problem** In a test of a new reference electrode, a chemist constructs a voltaic cell consisting of a  $\text{Zn}/\text{Zn}^{2+}$  half-cell and an  $\text{H}_2/\text{H}^+$  half-cell under the following conditions:

$$[\text{Zn}^{2+}] = 0.010 \text{ M} \quad [\text{H}^+] = 2.5 \text{ M} \quad P_{\text{H}_2} = 0.30 \text{ atm}$$

Calculate  $E_{\text{cell}}$  at 298.15 K.

**Plan** To apply the Nernst equation and determine  $E_{\text{cell}}$ , we must know  $E_{\text{cell}}^\circ$  and  $Q$ . We write the spontaneous reaction and calculate  $E_{\text{cell}}^\circ$  from standard electrode potentials (Appendix D). Then we substitute into Equation 21.10.

**Solution** Determining the cell reaction and  $E_{\text{cell}}^{\circ}$ :

Calculating  $Q$ :

$$Q = \frac{P_{\text{H}_2} \times [\text{Zn}^{2+}]}{[\text{H}^+]^2} = \frac{0.30 \times 0.010}{2.5^2} = 4.8 \times 10^{-4}$$

Solving for  $E_{\text{cell}}$  at 25°C (298.15 K), with  $n = 2$ :

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q \\ &= 0.76 \text{ V} - \frac{0.0592 \text{ V}}{2} \log (4.8 \times 10^{-4}) = 0.76 \text{ V} - (-0.098 \text{ V}) = \mathbf{0.86 \text{ V}} \end{aligned}$$

**Check** After you check the arithmetic, reason through the answer:  $E_{\text{cell}} > E_{\text{cell}}^{\circ}$  (0.86 > 0.76) because the  $\log Q$  term was negative, which is consistent with  $Q < 1$ .

### FOLLOW-UP PROBLEMS

**21.7A** A voltaic cell consists of a Cr/Cr<sup>3+</sup> half-cell and an Sn/Sn<sup>2+</sup> half-cell, with  $[\text{Sn}^{2+}] = 0.20 \text{ M}$  and  $[\text{Cr}^{3+}] = 1.60 \text{ M}$ . Use Appendix D to calculate  $E_{\text{cell}}$  at 298.15 K.

**21.7B** Consider a voltaic cell based on the following reaction:

If  $[\text{Cu}^{2+}] = 0.30 \text{ M}$ , what must  $[\text{Fe}^{2+}]$  be to increase  $E_{\text{cell}}$  by 0.25 V above  $E_{\text{cell}}^{\circ}$  at 25°C?

**SOME SIMILAR PROBLEMS** 21.68–21.71

## Following Changes in Potential During Cell Operation

As with any voltaic cell, the potential of a zinc-copper cell changes during cell operation because the concentrations of the components do. Because both of the other components are solids, the only variables are  $[\text{Cu}^{2+}]$  and  $[\text{Zn}^{2+}]$ :

In this section, we follow the potential as the zinc-copper cell operates.

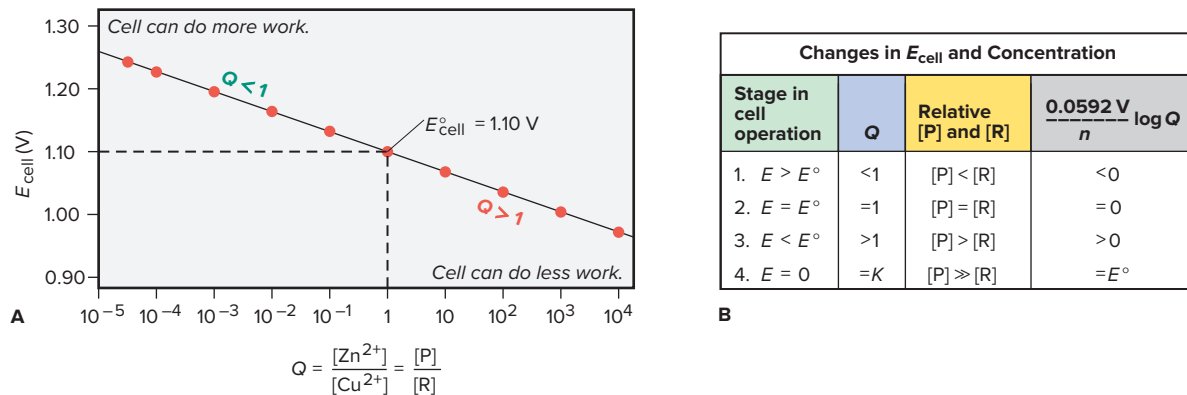

1. *Starting point of cell operation.* The positive  $E_{\text{cell}}^{\circ}$  (1.10 V) means that this reaction proceeds *spontaneously* to the right at standard-state conditions,  $[\text{Zn}^{2+}] = [\text{Cu}^{2+}] = 1 \text{ M}$  ( $Q = 1$ ). But, if we start the cell when  $[\text{Zn}^{2+}] < [\text{Cu}^{2+}]$  ( $Q < 1$ ), for example, when  $[\text{Zn}^{2+}] = 1.0 \times 10^{-4} \text{ M}$  and  $[\text{Cu}^{2+}] = 2.0 \text{ M}$ , the cell potential starts out *higher* than the standard cell potential, because  $\log Q < 0$ :

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{2} \log \frac{[\text{Zn}^{2+}]}{[\text{Cu}^{2+}]} = 1.10 \text{ V} - \left( \frac{0.0592 \text{ V}}{2} \log \frac{1.0 \times 10^{-4}}{2.0} \right) \\ &= 1.10 \text{ V} - \left[ \frac{0.0592 \text{ V}}{2} (-4.30) \right] = 1.10 \text{ V} + 0.127 \text{ V} = 1.23 \text{ V} \end{aligned}$$

2. *Key stages during cell operation.* Using Equation 21.10, we identify four key stages of operation. Figure 21.11A on the next page shows the first three. The main point is that *as the cell operates, its potential decreases*. As product concentration ( $[\text{P}] = [\text{Zn}^{2+}]$ ) increases and reactant concentration ( $[\text{R}] = [\text{Cu}^{2+}]$ ) decreases,  $Q$  becomes larger, the term  $[(0.0592 \text{ V}/n) \log Q]$  becomes less negative (more positive), and  $E_{\text{cell}}$  decreases:

*Stage 1.*  $E_{\text{cell}} > E_{\text{cell}}^{\circ}$  when  $Q < 1$ : when the cell begins operation,  $[\text{Cu}^{2+}] > [\text{Zn}^{2+}]$ , so  $(0.0592 \text{ V}/n) \log Q < 0$  and  $E_{\text{cell}} > E_{\text{cell}}^{\circ}$ .

*Stage 2.*  $E_{\text{cell}} = E_{\text{cell}}^{\circ}$  when  $Q = 1$ : at the point when  $[\text{Cu}^{2+}] = [\text{Zn}^{2+}]$ ,  $Q = 1$ , so  $(0.0592 \text{ V}/n) \log Q = 0$  and  $E_{\text{cell}} = E_{\text{cell}}^{\circ}$ .

**Figure 21.11** The relation between  $E_{\text{cell}}$  and  $\log Q$  for the zinc-copper cell. **A**, A plot of  $E_{\text{cell}}$  vs.  $Q$  (on a logarithmic scale) decreases linearly. When  $Q < 1$  (left), the cell does relatively more work. When  $Q = 1$ ,  $E_{\text{cell}} = E_{\text{cell}}^\circ$ . When  $Q > 1$  (right), the cell does relatively less work. **B**, A summary of the changes in  $E_{\text{cell}}$  as this or any voltaic cell operates. ([ $\text{Zn}^{2+}$ ] is [P] for [product], and [ $\text{Cu}^{2+}$ ] is [R] for [reactant].)

*Stage 3.*  $E_{\text{cell}} < E_{\text{cell}}^\circ$  when  $Q > 1$ : as the  $[\text{Zn}^{2+}]/[\text{Cu}^{2+}]$  ratio continues to increase,  $(0.0592 \text{ V}/n) \log Q > 0$ , so  $E_{\text{cell}} < E_{\text{cell}}^\circ$ .

*Stage 4.*  $E_{\text{cell}} = 0$  when  $Q = K$ : eventually,  $(0.0592 \text{ V}/n) \log Q$  becomes so large that it equals  $E_{\text{cell}}^\circ$ , which means that  $E_{\text{cell}}$  is zero. This occurs *when the system reaches equilibrium: no more free energy is released, so the cell can do no more work.* At this point, we say that a battery is “dead.”

Figure 21.11B summarizes these four key stages during operation of a voltaic cell.

3.  $Q/K$  and the work the cell can do. At equilibrium, Equation 21.10 becomes

$$0 = E_{\text{cell}}^\circ - \frac{0.0592 \text{ V}}{n} \log K, \quad \text{which rearranges to} \quad E_{\text{cell}}^\circ = \frac{0.0592 \text{ V}}{n} \log K$$

Note that this result is identical to Equation 21.8, which we obtained from  $\Delta G^\circ$ . Solving for  $K$  of the zinc-copper cell ( $E_{\text{cell}}^\circ = 1.10 \text{ V}$ ),

$$\log K = \frac{2 \times E_{\text{cell}}^\circ}{0.0592 \text{ V}} \quad \text{so} \quad K = 10^{(2 \times 1.10 \text{ V})/0.0592 \text{ V}} = 10^{37.16} = 1.4 \times 10^{37}$$

As you can see, this cell does work until  $[\text{Zn}^{2+}]/[\text{Cu}^{2+}]$  is *very* high.

The three relations between initial  $Q/K$  and  $E_{\text{cell}}$  are

- If  $Q/K < 1$ ,  $E_{\text{cell}}$  is positive for the reaction *as written*. The smaller  $Q/K$  is, the greater the value of  $E_{\text{cell}}$ , and the more electrical work the cell can do.
- If  $Q/K = 1$ ,  $E_{\text{cell}} = 0$ . The cell is at equilibrium and can no longer do work.
- If  $Q/K > 1$ ,  $E_{\text{cell}}$  is negative for the reaction as written. The reverse reaction will take place, and the cell will do work until  $Q/K$  equals 1 at equilibrium.

## Concentration Cells

If you mix a concentrated solution of a substance with a dilute solution of it, the final solution has an intermediate concentration. A **concentration cell** employs this simple, spontaneous change to generate electrical energy: different concentrations of species involved in the same half-reaction are in separate half-cells, and the cell does work until the concentrations become equal.

**Finding  $E_{\text{cell}}$  for a Concentration Cell** Suppose a voltaic cell has the  $\text{Cu}/\text{Cu}^{2+}$  half-reaction in both compartments. The cell reaction is the sum of identical half-reactions, written in opposite directions. The *standard* cell potential,  $E_{\text{cell}}^\circ$ , is zero because the *standard* electrode potentials are both based on  $1 \text{ M Cu}^{2+}$ , so they cancel. As we said, however, *in a concentration cell, the concentrations are different*. Thus, even though

**Figure 21.12** A concentration cell based on the  $\text{Cu}/\text{Cu}^{2+}$  half-reaction. **A**,  $E_{\text{cell}} > 0$  as long as the half-cell concentrations are different (lighter and darker colors). **B**, Half-cell concentrations are equal (same color), and the sizes of the electrodes (exaggerated for clarity) are different.

$E_{\text{cell}}^{\circ}$  is still zero, the *nonstandard* cell potential,  $E_{\text{cell}}$ , depends on the *ratio of concentrations*, so it is *not* zero.

For the final concentrations to be equal, a concentration cell must have the dilute solution in the anode compartment and the concentrated solution in the cathode compartment. For example, let's use  $0.10 M \text{Cu}^{2+}$  in the anode half-cell and  $1.0 M \text{Cu}^{2+}$ , a 10-fold higher concentration, in the cathode half-cell (Figure 21.12A):

The overall cell reaction is the sum of the half-reactions:

The cell potential at the initial concentrations of  $0.10 M$  (dilute) and  $1.0 M$  (concentrated), with  $n = 2$ , is obtained from the Nernst equation:

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{2} \log \frac{[\text{Cu}^{2+}]_{\text{dil}}}{[\text{Cu}^{2+}]_{\text{conc}}} = 0 \text{ V} - \left( \frac{0.0592 \text{ V}}{2} \log \frac{0.10 M}{1.0 M} \right) \\ &= 0 \text{ V} - \left[ \frac{0.0592 \text{ V}}{2} (-1.00) \right] = 0.0296 \text{ V} \end{aligned}$$

Since  $E_{\text{cell}}^{\circ}$  is zero,  $E_{\text{cell}}$  depends entirely on the term  $[(0.0592 \text{ V}/n) \log Q]$ .

**How a Concentration Cell Works** Let's see what is happening as this concentration cell operates:

- In the *anode (dilute) half-cell*, Cu atoms in the electrode give up electrons and the resulting  $\text{Cu}^{2+}$  ions enter the solution and make it *more* concentrated.
- In the *cathode (concentrated) half-cell*,  $\text{Cu}^{2+}$  ions gain the electrons and the resulting Cu atoms plate out on the electrode, which makes that solution *less* concentrated.

As in any voltaic cell,  $E_{\text{cell}}$  decreases until equilibrium is attained, which happens when  $[\text{Cu}^{2+}]$  is the same in both half-cells (Figure 21.12B). The same final concentration would result if we mixed the two solutions, but no electrical work would be done.

## SAMPLE PROBLEM 21.8

## Calculating the Potential of a Concentration Cell

**Problem** A voltaic cell consists of two Ag/Ag<sup>+</sup> half-cells. In half-cell A, the electrolyte is 0.010 M AgNO<sub>3</sub>; in half-cell B, it is 4.0×10<sup>-4</sup> M AgNO<sub>3</sub>. What is  $E_{\text{cell}}$  at 298.15 K?

**Plan** The standard half-cell reactions are identical, so  $E_{\text{cell}}^{\circ}$  is zero, and we find  $E_{\text{cell}}$  from the Nernst equation. Half-cell A has a higher [Ag<sup>+</sup>], so Ag<sup>+</sup> ions are reduced and plate out on electrode A. In half-cell B, Ag atoms of the electrode are oxidized and Ag<sup>+</sup> ions enter the solution. As in all voltaic cells, reduction occurs at the cathode, so it is positive.

**Solution** Writing the spontaneous reaction: The [Ag<sup>+</sup>] decreases in half-cell A and increases in half-cell B, so the spontaneous reaction is

Calculating  $E_{\text{cell}}$ , with  $n = 1$ :

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{1} \log \frac{[\text{Ag}^+]_{\text{dil}}}{[\text{Ag}^+]_{\text{conc}}} = 0 \text{ V} - \left( 0.0592 \text{ V} \log \frac{4.0 \times 10^{-4}}{0.010} \right) \\ &= 0.083 \text{ V} \end{aligned}$$

## FOLLOW-UP PROBLEMS

**21.8A** A voltaic cell consists of two Ni/Ni<sup>2+</sup> half-cells. In half-cell A, the electrolyte is 0.015 M Ni(NO<sub>3</sub>)<sub>2</sub>; in half-cell B, it is 0.40 M Ni(NO<sub>3</sub>)<sub>2</sub>. Calculate  $E_{\text{cell}}$  at 298.15 K.

**21.8B** A voltaic cell is built using two Au/Au<sup>3+</sup> half-cells. In half-cell A, [Au<sup>3+</sup>] = 7.0×10<sup>-4</sup> M, and in half-cell B, [Au<sup>3+</sup>] = 2.5×10<sup>-2</sup> M. What is  $E_{\text{cell}}$ , and which electrode is negative?

**SOME SIMILAR PROBLEMS** 21.72 and 21.73

**Applications of Concentration Cells** The principle of a concentration cell has many applications. Here, we'll discuss three:

1. *Measuring pH.* The most important laboratory application of this principle is in measuring [H<sup>+</sup>]. If we construct a concentration cell in which the cathode compartment is the standard hydrogen electrode and the anode compartment has the same apparatus dipping into a solution of unknown [H<sup>+</sup>], the half-reactions and overall reaction are

$E_{\text{cell}}^{\circ}$  is zero, but  $E_{\text{cell}}$  is *not* because the half-cells differ in [H<sup>+</sup>]. From the Nernst equation, with  $n = 2$ , we have

$$E_{\text{cell}} = E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{2} \log \frac{[\text{H}^+]_{\text{unknown}}^2}{[\text{H}^+]_{\text{standard}}^2}$$

Substituting 1 M for [H<sup>+</sup>]<sub>standard</sub> and 0 V for  $E_{\text{cell}}^{\circ}$  gives

$$E_{\text{cell}} = 0 \text{ V} - \frac{0.0592 \text{ V}}{2} \log \frac{[\text{H}^+]_{\text{unknown}}^2}{1^2} = -\frac{0.0592 \text{ V}}{2} \log [\text{H}^+]_{\text{unknown}}^2$$

Because  $\log x^2 = 2 \log x$  (see Appendix A), we obtain

$$E_{\text{cell}} = -\left[ \frac{0.0592 \text{ V}}{2} (2 \log [\text{H}^+]_{\text{unknown}}) \right] = -0.0592 \text{ V} \times \log [\text{H}^+]_{\text{unknown}}$$

Substituting  $-\log [\text{H}^+] = \text{pH}$ , we have

$$E_{\text{cell}} = 0.0592 \text{ V} \times \text{pH}$$

Thus, by measuring  $E_{\text{cell}}$ , we can find the pH.

**Figure 21.13** Laboratory measurement of pH. **A**, An older style pH meter includes a glass electrode (left) and a reference calomel electrode (right). **B**, Modern pH meters use a combination electrode.

For routine lab measurement of pH, a concentration cell made of two hydrogen electrodes is too bulky and difficult to maintain. Instead, we use a pH meter (Figure 21.13A). In a common, but older, design, two separate electrodes dip into the solution being tested:

- The *glass electrode* consists of an Ag/AgCl half-reaction immersed in HCl solution (usually 1.000 M) and enclosed by a thin (~0.05 mm) membrane made of a glass that is very sensitive to  $H^+$  ions.
- The *reference electrode*, usually a *saturated calomel electrode*, consists of a platinum wire immersed in calomel ( $Hg_2Cl_2$ ) paste, liquid Hg, and saturated KCl solution.

The glass electrode monitors the solution's  $[H^+]$  relative to its own fixed internal  $[H^+]$ , and the instrument converts the potential difference between the glass and reference electrodes into a measure of pH. In modern instruments, a *combination* electrode houses both electrodes in one tube (Figure 21.13B).

2. *Measuring ions selectively.* The pH electrode is one type of *ion-selective* (or *ion-specific*) electrode. These electrodes are designed with specialized membranes to selectively measure certain ion concentrations in a mixture of many ions, as in natural waters and soils. Biologists can implant a tiny ion-selective electrode in a single cell to study ion channels and receptors (Figure 21.14). Recent advances allow measurement in the femtomolar ( $10^{-15}$  M) range. Table 21.3 lists a few of the ions studied.

3. *Concentration cells in nerves.* A nerve cell membrane is embedded with enzyme “gates” that use the energy of one-third of the body’s ATP to create an ion gradient of low  $[Na^+]$  and high  $[K^+]$  inside and high  $[Na^+]$  and low  $[K^+]$  outside. As a result of these differences, the outside of a nerve cell is more positive than the inside. (The 1997 Nobel Prize in chemistry was shared by Jens C. Skou for elucidating this mechanism.) When the nerve membrane is stimulated, an electrical impulse is created as  $Na^+$  ions rush in spontaneously and the inside becomes more positive than the outside. This event is followed by  $K^+$  ions spontaneously rushing out, and the outside becomes more positive again; the whole process takes about 0.002 s! These large changes in charge in one membrane region stimulate the neighboring region and the electrical impulse moves along the cell.

## › Summary of Section 21.4

- › A spontaneous process has a negative  $\Delta G$  and a positive  $E_{cell}$ :  $\Delta G = -nFE_{cell}$ . The  $\Delta G$  of the cell reaction represents the maximum electrical work the voltaic cell can do.
- › The standard free energy change,  $\Delta G^\circ$ , is related to  $E_{cell}^\circ$  and to  $K$ .
- › For nonstandard conditions, the Nernst equation shows that  $E_{cell}$  depends on  $E_{cell}^\circ$  and a correction term based on  $Q$ .  $E_{cell}$  is high when  $Q$  is small (high [reactant]), and it decreases as the cell operates. At equilibrium,  $\Delta G$  and  $E_{cell}$  are zero, which means that  $Q = K$ .
- › Concentration cells have identical half-reactions, but solutions of differing concentration. They generate electrical energy as the concentrations become equal.
- › Ion-specific electrodes, such as the pH electrode, measure the concentration of one species.
- › The principle of the concentration cell—spontaneous movement of ions “down” a concentration gradient—creates an electrical impulse in a nerve cell.

### Some Ions Measured with Ion-Specific Electrodes

Table 21.3

Species Detected	Typical Sample
$NH_3/NH_4^+$	Industrial wastewater, seawater
$CO_2/HCO_3^-$	Blood, groundwater
$F^-$	Drinking water, urine, soil, industrial stack gases
$Br^-$	Grain, plant tissue
$I^-$	Milk, pharmaceuticals
$NO_3^-$	Soil, fertilizer, drinking water
$K^+$	Blood serum, soil, wine
$H^+$	Laboratory solutions, soil, natural waters

## 21.5 ELECTROCHEMICAL PROCESSES IN BATTERIES

Because of their compactness and mobility, batteries play a major role in everyday life, and in our increasingly wireless world, that role is growing. In general, a **battery** consists of self-contained voltaic cells arranged in series (plus-to-minus-to-plus, and so on), so that the individual voltages are added. In this section, we examine the three categories of batteries—primary, secondary, and fuel cells (flow batteries).

### Primary (Nonrechargeable) Batteries

A *primary battery* cannot be recharged, so the initial amounts of reactants are as far from equilibrium as is practical. This type of battery is discarded when the cell reaction has reached equilibrium, that is, when the battery is “dead.” We’ll discuss the alkaline battery, mercury and silver “button” batteries, and the primary lithium battery.

**Alkaline Battery** Invented in the 1860s, the common dry cell was a familiar item into the 1970s, but has now been replaced by the ubiquitous alkaline battery. The electrode materials are zinc and manganese dioxide, and the electrolyte is a basic paste of KOH and water (Figure 21.15). The half-reactions are

Overall (cell) reaction:

The alkaline battery powers portable radios, toys, flashlights, and so on, is safe, and comes in many sizes. It has no voltage drop, a long shelf life, and reliable performance in terms of power capability and stored energy.

**Figure 21.15** Alkaline battery.

Source: © Jill Braaten

**Mercury and Silver (Button) Batteries** Both mercury and silver batteries use a zinc container as the anode (reducing agent) in a basic medium. The mercury battery employs HgO as the oxidizing agent, the silver uses Ag<sub>2</sub>O, and both have a steel can around the cathode. The solid reactants are compacted with KOH and separated with moist paper. The half-reactions are

Overall (cell) reaction (mercury):

Overall (cell) reaction (silver):

Both cells are manufactured as button-sized batteries. The mercury cell, valued for its long life and stability, has been used in calculators, watches, and cameras; due to the toxicity of discarded mercury, the sale of mercury batteries is banned in many countries. The silver cell (Figure 21.16) is used in watches, cameras, heart pacemakers, and hearing aids because of its very steady output; its disadvantage is the high cost of silver.

**Figure 21.16** Silver button battery.

Source: © McGraw-Hill Education/Pat Watson, photographer

**Primary Lithium Batteries** The primary lithium battery is also widely used in watches and implanted medical products, and more recently in numerous remote-control devices. It offers an extremely high energy/mass ratio, producing 1 mol of  $e^-$  ( $1 F$ ) from less than 7 g of metal ( $\mathcal{M}$  of Li = 6.941 g/mol). The anode is lithium foil in a nonaqueous electrolyte. The cathode is one of several metal oxides in which lithium ions lie between oxide layers. Some pacemakers have a silver vanadium oxide (SVO;  $\text{AgV}_2\text{O}_{5.5}$ ) cathode and can provide power (1.5 to 3.5 V) for several years, but at a low rate because energy storage is limited (Figure 21.17). The half-reactions are

## Secondary (Rechargeable) Batteries

In contrast to a primary battery, a *secondary battery* is *rechargeable*; when it runs down, *electrical energy is supplied to reverse the cell reaction* and form more reactant. In other words, in a secondary battery, the voltaic cells are periodically converted to electrolytic cells to restore the starting *nonequilibrium* concentrations of the cell components. We'll discuss the common car battery, the nickel–metal hydride battery, and the lithium-ion battery, a secondary lithium battery.

**Lead-Acid Battery** A typical lead-acid car battery has six cells connected in series, each of which delivers about 2.1 V for a total of about 12 V. Each cell contains two lead grids packed with high-surface-area (spongy) Pb in the anode and high-surface-area  $\text{PbO}_2$  in the cathode. The grids are immersed in a solution of  $\sim 4.5 M$   $\text{H}_2\text{SO}_4$ . Fiberglass sheets between the grids prevent shorting due to physical contact (Figure 21.18, *next page*).

1. *Discharging.* When the cell discharges as a voltaic cell, it generates electrical energy:

Both half-reactions form  $\text{Pb}^{2+}$  ions, one through oxidation of Pb, the other through reduction of  $\text{PbO}_2$ . The  $\text{Pb}^{2+}$  forms  $\text{PbSO}_4(s)$  at both electrodes by reacting with  $\text{HSO}_4^-$ .

**Overall (cell) reaction (discharge):**

**Figure 21.17** Primary lithium battery.

Source: © 2015 Boston Scientific Corporation or its affiliates. All rights reserved.

Figure 21.18 Lead-acid battery.

2. *Recharging.* When the cell recharges as an electrolytic cell, it uses electrical energy and the half-cell and overall reactions are reversed.

*Overall (cell) reaction (recharge):*

Car and truck owners have relied on the lead-acid battery for over a century to provide the large burst of current needed to start the engine—and to do so for years, in hot and cold weather. The main problems with the lead-acid battery are loss of capacity due to corrosion of the positive (Pb) grid, detachment of the active material due to normal mechanical bumping, and formation of large  $\text{PbSO}_4$  crystals that hinder recharging.

**Nickel–Metal Hydride (Ni-MH) Battery** Concerns about the toxicity of cadmium in the once popular nickel-cadmium (nicad) battery have led to its replacement by the nickel–metal hydride (Ni-MH) battery. The anode half-reaction oxidizes the hydrogen absorbed within a metal alloy (such as  $\text{LaNi}_5$ ; designated M) in a basic (KOH) electrolyte, while nickel(III) in the form of  $\text{NiO}(\text{OH})$  is reduced at the cathode (Figure 21.19):

$$E_{\text{cell}} = 1.4 \text{ V}$$

The cell reaction is reversed during recharging. The Ni-MH battery is common in cordless razors, camera flash units, and power tools. It is lightweight, has high power, and is nontoxic, but it discharges significantly during storage.

Figure 21.19 Nickel–metal hydride battery.

Source: © McGraw-Hill Education/Stephen Frisch, photographer

Figure 21.20 Lithium-ion battery.

Source: © AP/Wide World Photos

**Lithium-Ion Battery** The secondary lithium-ion battery has an anode of Li atoms that lie between sheets of graphite (designated  $\text{Li}_x\text{C}_6$ ). The cathode is a lithium metal oxide, such as  $\text{LiMn}_2\text{O}_4$  or  $\text{LiCoO}_2$ , and a typical electrolyte is 1 M  $\text{LiPF}_6$  in an organic solvent, such as dimethyl carbonate mixed with methylethyl carbonate. Electrons flow through the circuit, while solvated  $\text{Li}^+$  ions flow from anode to cathode within the cell (Figure 21.20). The cell reactions are

$$E_{\text{cell}} = 3.7 \text{ V}$$

The cell reaction is reversed during recharging. The lithium-ion battery powers countless laptop computers, tablets, cell phones, and camcorders. Its key drawbacks are cost and flammability of the organic solvent.

## Fuel Cells

In contrast to primary and secondary batteries, a **fuel cell**, sometimes called a *flow battery*, is not self-contained. The reactants (usually a fuel and oxygen) enter the cell, and the products leave, *generating electricity through controlled combustion (oxidation)* of the fuel. The fuel does not burn because, as in other voltaic cells, the half-reactions are separated, and the electrons move through an external circuit.

The most common fuel cell being developed for use in cars is the *proton exchange membrane (PEM) cell*, which uses  $\text{H}_2$  as the fuel and has an operating temperature of around  $80^\circ\text{C}$  (Figure 21.21). The cell reactions are

**Figure 21.21** Proton exchange membrane cell: a hydrogen fuel cell.

**How  $\text{H}_2$  Fuel Cells Work** Reaction rates are lower in fuel cells than in other batteries, so an *electrocatalyst* is used to decrease the activation energy (Section 16.7). The PEM cell's electrodes are made of a nanocomposite consisting of a Pt-based catalyst deposited on graphite. These are embedded in a polymer electrolyte membrane having a perfluoroethylene backbone ( $-\text{[F}_2\text{C}-\text{CF}_2\text{]}_n-$ ) with attached sulfonic acid groups ( $\text{RSO}_3^-$ ) that play a key role in ferrying protons from anode to cathode.

- *At the anode*, two  $\text{H}_2$  molecules adsorb onto the catalyst and are split and oxidized. From each  $\text{H}_2$ , two  $\text{e}^-$  travel through the wire to the cathode, while two  $\text{H}^+$  are hydrated and migrate through the electrolyte as  $\text{H}_3\text{O}^+$ .
