- *At the cathode*, an  $\text{O}_2$  molecule is believed to adsorb onto the catalyst, which provides an  $\text{e}^-$  to form  $\text{O}_2^-$ . One  $\text{H}_3\text{O}^+$  donates its  $\text{H}^+$  to the  $\text{O}_2^-$ , forming  $\text{HO}_2^-$  (that is,  $\text{HO}-\text{O}$ ). The  $\text{O}-\text{O}$  bond stretches and breaks as another  $\text{H}_3\text{O}^+$  gives its  $\text{H}^+$  and the catalyst provides another  $\text{e}^-$ : the first  $\text{H}_2\text{O}$  has formed. In similar fashion, a third  $\text{H}^+$  and  $\text{e}^-$  attach to the freed  $\text{O}$  atom to form  $\text{OH}$ , and a fourth  $\text{H}^+$  and  $\text{e}^-$  are transferred to form the second  $\text{H}_2\text{O}$ . Both water molecules desorb and leave the cell.

**Applications of Fuel Cells** Hydrogen fuel cells have been used for years to provide electricity *and* water during space flights. Similar ones have begun to supply electric power for residential needs, and every major car manufacturer has a fuel-cell model. Fuel cells produce no pollutants and convert about 75% of a fuel's bond energy into power, compared to 40% for a coal-fired power plant and 25% for a gasoline engine.

## › Summary of Section 21.5

- › Batteries are voltaic cells arranged in series and are classified as primary (e.g., alkaline, mercury, silver, and lithium), secondary (e.g., lead-acid, nickel-metal hydride, and lithium-ion), or fuel cells.
- › Supplying electricity to a rechargeable (secondary) battery reverses the redox reaction, re-forming reactant.
- › Fuel cells generate a current through the controlled oxidation of a fuel such as  $\text{H}_2$ .

## 21.6 CORROSION: AN ENVIRONMENTAL VOLTAIC CELL

If you think all spontaneous electrochemical processes are useful, like those in batteries and fuel cells, consider the problem of **corrosion**, which causes tens of billions of dollars of damage to cars, ships, buildings, and bridges each year. This natural process, which oxidizes metals to their oxides and sulfides, shares many similarities with the operation of a voltaic cell. We focus on the corrosion of iron, but several other metals, such as copper and silver, also corrode.

### The Corrosion of Iron

The most common and economically destructive form of corrosion is the rusting of iron. About 25% of the steel produced in the United States each year is for replacing steel in which the iron has corroded. Rust is *not* a direct product of the reaction between iron and oxygen but arises through a complex electrochemical process. Let's look at the facts concerning iron corrosion and then use the features of a voltaic cell to explain them:

- Fact 1. Iron does not rust in dry air; moisture must be present.
- Fact 2. Iron does not rust in air-free water; oxygen must be present.
- Fact 3. Iron loss and rust formation occur at *different* places on the *same* object.
- Fact 4. Iron rusts more quickly at low pH (high  $[H^+]$ ).
- Fact 5. Iron rusts more quickly in ionic solutions (aqueous salt solutions).
- Fact 6. Iron rusts more quickly in contact with a less active metal (such as Cu) and more slowly in contact with a more active metal (such as Zn).

Two separate redox processes occur during corrosion:

1. *The loss of iron.* Picture the surface of a piece of iron (Figure 21.22). A strain, ridge, or dent in contact with water is typically the site of iron loss (fact 1). This site is called an *anodic region* because the following oxidation half-reaction occurs there:

Once the iron atoms lose electrons, the damage to the object has been done, and a pit forms where the iron is lost.

The freed electrons move through the external circuit—the piece of iron itself—until they reach a region of relatively high  $[O_2]$  (fact 2), usually the air near the edge of a water droplet that surrounds the newly formed pit. At this *cathodic region*, the electrons released from the iron atoms reduce  $O_2$ :

**Figure 21.22** The corrosion of iron. **A**, Close-up view of an iron surface. Corrosion usually occurs at a surface irregularity. **B**, A small area of the surface, showing the steps in the corrosion process.

Source: A: © Vincent Roy mastweb/Alamy

This portion of the corrosion process (the sum of these two half-reactions) occurs without any rust forming:

2. *The rusting process.* Rust forms in another redox reaction. The  $\text{Fe}^{2+}$  ions formed at the anodic region disperse through the water and react with  $\text{O}_2$ , often away from the pit, to form the  $\text{Fe}^{3+}$  in rust (fact 3). The overall reaction for this step is

[The coefficient  $n$  for  $\text{H}_2\text{O}$  appears because rust,  $\text{Fe}_2\text{O}_3 \cdot n\text{H}_2\text{O}$ , may have a variable number of waters of hydration.] The rust deposit is incidental to the real damage, which is the loss of iron that weakens the strength of the object. Adding the two previous equations gives the overall equation for the loss and rusting of iron:

Other species ( $2\text{Fe}^{2+}$  and  $2\text{H}_2\text{O}$ ) also cancel, but we showed the canceled  $\text{H}^+$  ions to emphasize that they act as a catalyst: they speed the process as they are used up in one step and created in another. For this reason, rusting is faster at low pH (high  $[\text{H}^+]$ ) (fact 4). Ionic solutions speed rusting by improving the conductivity of the aqueous medium near the anodic and cathodic regions (fact 5). The effect of ions is especially evident on ocean-going vessels (Figure 21.23) and on the underbodies and around the wheel wells of cars driven in cold climates, where salts are used to melt ice on slippery roads. (We discuss fact 6 in the next subsection.)

Thus, in some key ways, corrosion resembles the operation of a voltaic cell:

- Anodic and cathodic regions are physically separated.
- The regions are connected via an external circuit through which the electrons travel.
- In the anodic region, iron behaves like an active electrode, whereas in the cathodic region, it is inactive.
- The moisture surrounding the pit functions somewhat like an electrolyte and salt bridge, a solution of ions and a means for them to move and keep the solution neutral.

## Protecting Against the Corrosion of Iron

Corrosion is prevented by eliminating corrosive factors. Washing road salt off automobile bodies removes ions. Painting an object keeps out  $\text{O}_2$  and moisture. Plating chromium on plumbing fixtures is a more permanent method, as is “blueing” of gun barrels and other steel objects, in which a coating of  $\text{Fe}_3\text{O}_4$  (magnetite) is bonded to the surface.

The final point regarding corrosion (fact 6) concerns the relative activity of other metals in contact with iron. The essential idea is that *iron functions as both anode and cathode in the rusting process, but it is lost only at the anode.* Thus,

1. *Corrosion increases when iron behaves more like the anode.* When iron is in contact with a *less* active metal (weaker reducing agent), such as copper, it loses electrons more readily (its anodic function is enhanced; Figure 21.24A). For example, when iron plumbing is connected directly to copper plumbing, the iron pipe corrodes

**Figure 21.23** Enhanced corrosion at sea. The high ion concentration of seawater enhances the corrosion of iron in hulls and anchors.

Source: © David Weintraub/Science Source

**Figure 21.24** The effect of metal-metal contact on the corrosion of iron. **A**, Fe in contact with Cu corrodes faster. **B**, Fe in contact with Zn does not corrode. This method of preventing corrosion is known as *cathodic protection*.

**Figure 21.25** The use of a sacrificial anode to prevent iron corrosion. In cathodic protection, an active metal, such as zinc, magnesium, or aluminum, acts as the anode and is sacrificed instead of the iron.

rapidly. Nonconducting rubber or plastic spacers are placed between the metals to avoid this problem.

2. *Corrosion decreases when iron behaves more like the cathode.* In *cathodic protection*, the most effective way to prevent corrosion, iron makes contact with a *more* active metal (stronger reducing agent), such as zinc. The iron becomes the cathode and remains intact, while the zinc acts as the anode and loses electrons (Figure 21.24B). Coating steel with a “sacrificial” layer of zinc is called *galvanizing*. In addition to blocking physical contact with  $\text{H}_2\text{O}$  and  $\text{O}_2$ , the zinc (or other active metal) is “sacrificed” (oxidized) instead of the iron. Sacrificial anodes are placed underwater and underground to protect iron and steel pipes, tanks, oil rigs, and so on. Magnesium and aluminum are often used because they are much more active than iron and, thus, act as the anode (Figure 21.25). Moreover, they form adherent oxide coatings, which slow their own corrosion.

### › Summary of Section 21.6

- › Corrosion damages metal structures through a natural electrochemical process.
- › Iron corrosion occurs in the presence of oxygen and moisture and is increased by high  $[\text{H}^+]$ , high  $[\text{ion}]$ , or contact with a less active metal, such as Cu.
- › Fe is oxidized and  $\text{O}_2$  is reduced in one redox reaction, while  $\text{Fe}^{2+}$  is oxidized and  $\text{O}_2$  is reduced to form rust (hydrated form of  $\text{Fe}_2\text{O}_3$ ) in another redox reaction that often takes place at a different location.
- › Because Fe functions as both anode and cathode in the corrosion process, an iron object can be protected by physically coating it or by joining it to a more active metal (such as Zn, Mg, or Al), which acts as the anode in place of the Fe.

## 21.7 ELECTROLYTIC CELLS: USING ELECTRICAL ENERGY TO DRIVE NONSPONTANEOUS REACTIONS

In contrast to a voltaic cell, which generates electrical energy from a spontaneous reaction, *an electrolytic cell requires electrical energy from an external source to drive a nonspontaneous redox reaction.* (Industrial electrolysis is discussed in Chapter 22.)

### Construction and Operation of an Electrolytic Cell

Let’s see how an electrolytic cell operates by constructing one from a voltaic cell. Consider a tin-copper voltaic cell (Figure 21.26A). The Sn anode will gradually be oxidized to  $\text{Sn}^{2+}$  ions, which enter the electrolyte, and the  $\text{Cu}^{2+}$  ions will gradually be reduced and plate out on the Cu cathode because the cell reaction is spontaneous in that direction.

For the voltaic cell:

Therefore, the *reverse* cell reaction is *nonspontaneous* and cannot happen on its own. But, we can make it happen by supplying an electric potential *greater than*  $E_{\text{cell}}^{\circ}$  from an external source. In effect, we convert the voltaic cell into an electrolytic cell—*anode becomes cathode, and cathode becomes anode* (Figure 21.26B).

For the electrolytic cell:

In an electrolytic cell, as in a voltaic cell, *oxidation takes place at the anode and reduction takes place at the cathode.* Note, however, that *the direction of electron flow and the signs of the electrodes are reversed.*

**Figure 21.26** The tin-copper reaction as the basis of a voltaic and an electrolytic cell. **A**, The spontaneous reaction between Sn and  $\text{Cu}^{2+}$  generates 0.48 V in a voltaic cell. **B**, If more than 0.48 V is supplied, the nonspontaneous (reverse) reaction between Cu and  $\text{Sn}^{2+}$  occurs. Note the changes in electrode charges and direction of electron flow.

To understand these differences, we focus on the *cause* of the electron flow:

- In a voltaic cell, electrons are generated *in* the anode, so it is *negative*, and they are *removed from* the cathode, so it is *positive*.
- In an electrolytic cell, an external power source supplies electrons *to* the cathode, so it is *negative*, and removes them *from* the anode, so it is *positive*.

A rechargeable battery is a voltaic cell when it is discharging and an electrolytic cell when it is recharging. Let's compare these two functions in a lead-acid car battery (Figure 21.27; see also Figure 21.18):

- In the discharge mode (voltaic cell), oxidation occurs at electrode I, thus making that *negative* electrode the anode and the *positive* electrode (electrode II) the cathode.
- In the recharge mode (electrolytic cell), reduction occurs at electrode I, making that *negative* electrode the cathode and the *positive* electrode (electrode II) the anode.

**Figure 21.27** The processes occurring during the discharge (*top*) and recharge (*bottom*) of a lead-acid battery.

Table 21.4

Comparison of Voltaic and Electrolytic Cells

Cell Type	$\Delta G$	$E_{\text{cell}}$	Electrode		
			Name	Process	Sign
Voltaic	<0	>0	Anode	Oxidation	–
Voltaic	<0	>0	Cathode	Reduction	+
Electrolytic	>0	<0	Anode	Oxidation	+
Electrolytic	>0	<0	Cathode	Reduction	–

Table 21.4 summarizes the processes and signs in the two types of cells.

## Predicting the Products of Electrolysis

**Electrolysis** is the splitting (lysing) of a substance by the input of electrical energy and is often used to decompose a compound into its elements, as you'll see for chlorine, aluminum, copper, and several others in Chapter 22. Water was first electrolyzed to  $\text{H}_2$  and  $\text{O}_2$  in 1800, and the process is still used to produce these gases in ultrahigh purity. The electrolyte in an electrolytic cell can be the pure compound (such as a molten salt), a mixture of molten salts, or an aqueous solution of a salt. As you'll see, the products depend on atomic properties and several other factors.

**Electrolysis of Pure Molten Salts** If the salt is pure, predicting the products of its electrolysis is straightforward: *the cation will be reduced and the anion oxidized*. The electrolyte is the molten salt itself, and the ions are attracted by the oppositely charged electrodes.

Consider the electrolysis of molten (fused) calcium chloride. The two species present are  $\text{Ca}^{2+}$  and  $\text{Cl}^-$ , so  $\text{Ca}^{2+}$  ion is reduced and  $\text{Cl}^-$  ion is oxidized:

Calcium is prepared industrially this way, as are several other active metals, such as Na and Mg, and the halogens  $\text{Cl}_2$  and  $\text{Br}_2$ .

**Electrolysis of Mixed Molten Salts** More typically, the electrolyte is a mixture of molten salts being electrolyzed to obtain one of the metals. How can we tell which species will react at which electrode? The general rule for all electrolytic cells identifies them:

- *The more easily reduced species (stronger oxidizing agent) is reduced at the cathode.*
- *The more easily oxidized species (stronger reducing agent) is oxidized at the anode.*

Unfortunately, for molten salts, we *cannot* use  $E^\circ$  values to tell the relative strength of the oxidizing and reducing agents, because those values refer to the reduction of the *aqueous ion to the free element*,  $\text{M}^{n+}(\text{aq}) + ne^- \longrightarrow \text{M}(s)$ , under standard-state conditions. Instead, we use periodic trends of atomic properties to predict which ion gains or loses electrons more easily (Sections 8.3 and 9.5):

- If a metal holds its electrons *more* tightly than another, it has a higher ionization energy (IE). Thus, as a cation, it gains electrons more easily, so it is the stronger oxidizing agent and is reduced at the cathode.
- If a nonmetal holds its electrons *less* tightly than another, it has a lower electronegativity (EN). Thus, as an anion, it loses electrons more easily, so it is the stronger reducing agent and is oxidized at the anode.

To summarize, in a mixture of molten salts, the metal with the higher IE is the cation that is reduced, while the nonmetal with the lower EN is the anion that is oxidized.

## SAMPLE PROBLEM 21.9

## Predicting the Electrolysis Products of a Molten Salt Mixture

**Problem** A chemical engineer melts a naturally occurring mixture of NaBr and MgCl<sub>2</sub> and decomposes it in an electrolytic cell. Predict the substance formed at each electrode, and write balanced half-reactions and the overall cell reaction.

**Plan** We have to determine which metal and nonmetal will form more easily at each electrode. We list the ions as oxidizing or reducing agents and then use periodic trends to determine which metal ion is more easily reduced and which nonmetal ion more easily oxidized.

**Solution** Listing the ions as oxidizing or reducing agents:

The possible oxidizing agents are Na<sup>+</sup> and Mg<sup>2+</sup>; these cations may undergo reduction.

The possible reducing agents are Br<sup>-</sup> and Cl<sup>-</sup>; these anions may undergo oxidation.

Determining the cathode product (more easily reduced cation): Mg is to the right of Na in Period 3. IE increases from left to right, so it is harder to remove e<sup>-</sup> from Mg. Thus, Mg<sup>2+</sup> has a greater attraction for e<sup>-</sup> and is more easily reduced (stronger oxidizing agent). Mg<sup>2+</sup> will be reduced preferentially at the cathode:

Determining the anode product (more easily oxidized anion): Br is below Cl in Group 7A(17). EN decreases down the group, so Br accepts e<sup>-</sup> less readily. Thus, Br<sup>-</sup> loses its e<sup>-</sup> more easily and is more easily oxidized (stronger reducing agent). Br<sup>-</sup> will be oxidized preferentially at the anode:

Writing the overall cell reaction:

**Comment** The cell temperature must be high enough to keep the salt mixture molten. In this case, the temperature is greater than the melting point of Mg, so it appears as a liquid in the equation, and greater than the boiling point of Br<sub>2</sub>, so it appears as a gas.

## FOLLOW-UP PROBLEMS

**21.9A** The most ionic and least ionic of the common alkali halides are, respectively, CsF and LiI. A solid mixture of these compounds is melted and electrolyzed. Determine which metal and nonmetal form at the electrodes, and write the overall cell reaction.

**21.9B** A sample of AlBr<sub>3</sub> contaminated with KF is melted and electrolyzed. Determine the electrode products, and write the overall cell reaction.

**SOME SIMILAR PROBLEMS** 21.89–21.92

**Electrolysis of Water and Nonstandard Half-Cell Potentials** Before we analyze the electrolysis products of aqueous salt solutions, let's examine the electrolysis of water itself. Very pure water is difficult to electrolyze because so few ions are present to conduct a current. However, if we add a small amount of a salt that cannot be electrolyzed (such as Na<sub>2</sub>SO<sub>4</sub>), electrolysis proceeds rapidly. An electrolytic cell with separate compartments for H<sub>2</sub> and O<sub>2</sub> is used (Figure 21.28). At the anode, water is oxidized; note that the oxidation number (O.N.) of O changes from -2 in H<sub>2</sub>O to 0 in O<sub>2</sub>:

**Figure 21.28** The electrolysis of water. Twice as much H<sub>2</sub> forms as O<sub>2</sub>. Source: © McGraw-Hill Education/Stephen Frisch, photographer

At the cathode, water is reduced; note that the O.N. of H changes from +1 in H<sub>2</sub>O to 0 in H<sub>2</sub>:

Doubling the cathode half-reaction to make e<sup>-</sup> lost equal e<sup>-</sup> gained, adding the half-reactions (which involves combining the H<sup>+</sup> and OH<sup>-</sup> into H<sub>2</sub>O and canceling e<sup>-</sup> and excess H<sub>2</sub>O), and calculating E<sub>cell</sub> gives the overall reaction:

Note that, because [H<sup>+</sup>] and [OH<sup>-</sup>] are 1.0×10<sup>-7</sup> M rather than the standard-state value of 1 M, these electrode potentials are *not* standard electrode potentials and are designated with E, not E°. In aqueous ionic solutions, [H<sup>+</sup>] and [OH<sup>-</sup>] are also approximately 10<sup>-7</sup> M, so we use these nonstandard E<sub>half-cell</sub> values to predict electrode products.

**Electrolysis of Aqueous Salt Solutions and the Effect of Overvoltage** Aqueous salt solutions are mixtures of ions *and* water, so we have to compare the electrode potentials of the ions and of water to predict the electrode products.

1. *Predicting the electrode products.* When two half-reactions are possible at an electrode:

- The reduction with the less negative (more positive) electrode potential occurs.
- The oxidation with the less positive (more negative) electrode potential occurs.

What happens, for instance, when a solution of potassium iodide is electrolyzed?

- The possible *oxidizing agents* are K<sup>+</sup> and H<sub>2</sub>O; their reduction half-reactions are

The less *negative* electrode potential for water means that it is much easier to reduce H<sub>2</sub>O than K<sup>+</sup>, so H<sub>2</sub> forms at the cathode. No potassium metal forms at the cathode.

- The possible *reducing agents* are I<sup>-</sup> and H<sub>2</sub>O; their oxidation half-reactions are

The less *positive* electrode potential for iodide ion means that it is easier to oxidize I<sup>-</sup> than H<sub>2</sub>O, so I<sub>2</sub> forms at the anode.

2. *The effect of overvoltage.* The products predicted from a comparison of electrode potentials are not always the actual products. For gases to be produced at metal electrodes, additional voltage is required. This increment above the expected voltage is the **overvoltage**. It is 0.4–0.6 V for H<sub>2</sub>(g) or O<sub>2</sub>(g) and is due to the large activation energy (Section 16.5) required for a gas to form at the electrode.

Overvoltage has major practical significance. A multibillion-dollar example is the industrial production of chlorine from concentrated NaCl solution. Water is easier to reduce than Na<sup>+</sup>, so H<sub>2</sub> forms at the cathode, even *with* an overvoltage of 0.6 V:

But Cl<sub>2</sub> *does* form at the anode, even though a comparison of the electrode potentials alone would lead us to predict that O<sub>2</sub> should form:

An overvoltage of  $\sim 0.6$  V for  $O_2$  makes  $Cl_2$  the product that is easier to form. Keeping  $[Cl^-]$  high also favors its formation. Thus,  $Cl_2$ , one of the 10 most heavily produced chemicals, is formed from plentiful natural sources of aqueous sodium chloride (Chapter 22).

3. *A summary: which product at which electrode.* Experiments have shown the elements that can be prepared electrolytically from aqueous solutions of their salts:

- Cations of less active metals, including gold, silver, copper, chromium, platinum, and cadmium, *are* reduced to the metal.
- Cations of more active metals, including those in Groups 1A(1) and 2A(2) and Al from 3A(13), *are not* reduced. Water is reduced to  $H_2$  and  $OH^-$  instead.
- Anions that *are* oxidized, because of overvoltage from  $O_2$  formation, include the halides ( $[Cl^-]$  must be high), except for  $F^-$ .
- Anions that *are not* oxidized include  $F^-$  and common oxoanions, such as  $SO_4^{2-}$ ,  $CO_3^{2-}$ ,  $NO_3^-$ , and  $PO_4^{3-}$  because the central nonmetal in these oxoanions is already in its highest oxidation state. Water is oxidized to  $O_2$  and  $H^+$  instead.

### Student Hot Spot

Student data indicate that you may struggle with determining the products of electrolysis. Access the Smartbook to view additional Learning Resources on this topic.

### SAMPLE PROBLEM 21.10

### Predicting the Electrolysis Products of Aqueous Salt Solutions

**Problem** Use half-reactions to show which product forms at each electrode during the electrolysis of aqueous solutions of the following salts:

(a) KBr      (b)  $AgNO_3$       (c)  $MgSO_4$

**Plan** We identify the reacting ions and compare their electrode potentials with those of water, taking the additional 0.4–0.6 V overvoltage into account. The reduction half-reaction with the less negative electrode potential occurs at the cathode, and the oxidation half-reaction with the less positive electrode potential occurs at the anode.

#### Solution

Despite the overvoltage, which makes  $E$  for the reduction of water between  $-0.8$  V and  $-1.0$  V,  $H_2O$  is still easier to reduce than  $K^+$ , so  $H_2(g)$  forms at the cathode.

Because of the overvoltage, which makes  $E$  for the oxidation of water between 1.2 V and 1.4 V,  $Br^-$  is easier to oxidize than water, so  $Br_2(l)$  forms at the anode (see photo).

As the cation of an inactive metal,  $Ag^+$  is a better oxidizing agent than  $H_2O$ , so  $Ag(s)$  forms at the cathode.  $NO_3^-$  cannot be oxidized, because N is already in its highest (+5) oxidation state. Thus,  $O_2(g)$  forms at the anode:

Like  $K^+$  in part (a),  $Mg^{2+}$  cannot be reduced in the presence of water, so  $H_2(g)$  forms at the cathode. The  $SO_4^{2-}$  ion cannot be oxidized because S is in its highest (+6) oxidation state. Thus,  $H_2O$  is oxidized, and  $O_2(g)$  forms at the anode:

### FOLLOW-UP PROBLEMS

**21.10A** Use half-reactions to show which product forms at each electrode when an aqueous solution of lead(II) nitrate is electrolyzed.

**21.10B** Use half-reactions to show which product forms at each electrode in the electrolysis of aqueous  $AuBr_3$ .

**SOME SIMILAR PROBLEMS** 21.97–21.100

Electrolysis of aqueous KBr.

## Stoichiometry of Electrolysis: The Relation Between Amounts of Charge and Products

Since charge flowing through an electrolytic cell yields products at the electrodes, it makes sense that more product forms when more charge flows. This relationship was first determined experimentally in the 1830s by Michael Faraday:

- *Faraday's law of electrolysis: the amount of substance produced at each electrode is directly proportional to the quantity of charge flowing through the electrolytic cell.*

Each balanced half-reaction shows the amounts (mol) of reactant, electrons, and product involved in the change, so it contains the information we need to answer such questions as “How much material will form from a given quantity of charge?” or, conversely, “How much charge is needed to produce a given amount of material?”

**Measuring Current to Find Charge** We cannot measure charge directly, but we *can* measure *current*, the charge flowing per unit time. The SI unit of current is the **ampere (A)**, which is defined as a charge of 1 coulomb (C) flowing through a conductor in 1 second (s):

$$\text{Current (A)} = \text{charge (C)}/\text{time (s)} \quad \text{or} \quad 1 \text{ A} = 1 \text{ C/s} \quad (21.11)$$

Thus, the current multiplied by the time gives the charge:

$$\text{Current} \times \text{time} = \text{charge} \quad \text{or} \quad \text{A} \times \text{s} = \frac{\text{C}}{\text{s}} \times \text{s} = \text{C}$$

Therefore, by measuring the current *and* the time during which the current flows, we find the charge, which relates to the amount of product (Figure 21.29).

**Faraday's Law and the Stoichiometry of Electrolysis** Problems based on Faraday's law often ask you to calculate current, mass of material, or time. As we said, the electrode half-reaction provides the key to solving these problems because it relates the mass of product to a certain quantity of charge. To apply Faraday's law:

1. Balance the half-reaction to find the amount (mol) of electrons needed per mole of product.
2. Use the Faraday constant ( $F = 9.65 \times 10^4 \text{ C/mol e}^-$ ) to find the quantity of charge.
3. Depending on the question, do one of the following:
  - a. Use the molar mass to find the charge needed for a given mass of product, or vice versa.
  - b. Use the mass of product and the given current to find the time needed, or vice versa.

Here is a typical problem in practical electrolysis: how long does it take to produce 3.0 g of  $\text{Cl}_2(\text{g})$  by electrolysis of aqueous NaCl using a power supply with a current of 12 A? The problem asks for the time needed to produce a certain mass, so let's first relate mass to amount (mol) of electrons to find the charge needed. Then, we'll relate the charge to the current to find the time.

The half-reaction tells us that 2 mol of electrons are lost to form 1 mol of  $\text{Cl}_2$  and we'll use this relationship as a conversion factor:

We convert the given mass of  $\text{Cl}_2$  to amount (mol) of  $\text{Cl}_2$ , use the conversion factor from the half-reaction, and multiply by the Faraday constant to find the total charge:

$$\begin{aligned} \text{Charge (C)} &= 3.0 \text{ g Cl}_2 \times \frac{1 \text{ mol Cl}_2}{70.90 \text{ g Cl}_2} \times \frac{2 \text{ mol e}^-}{1 \text{ mol Cl}_2} \times \frac{9.65 \times 10^4 \text{ C}}{1 \text{ mole e}^-} \\ &= 8.2 \times 10^3 \text{ C} \end{aligned}$$

**Figure 21.29** A summary diagram for the stoichiometry of electrolysis.

Now we use the relationship between charge and current to find the time needed:

$$\begin{aligned}\text{Time (s)} &= \frac{\text{charge (C)}}{\text{current (A, or C/s)}} = 8.2 \times 10^3 \text{ C} \times \frac{1 \text{ s}}{12 \text{ C}} \\ &= 6.8 \times 10^2 \text{ s} (\sim 11 \text{ min})\end{aligned}$$

Note that the entire calculation follows Figure 21.29 until the last step, which asks for the time that the given current must flow:

Sample Problem 21.11 applies these ideas in an important industrial setting.

### SAMPLE PROBLEM 21.11

### Applying the Relationship Among Current, Time, and Amount of Substance

**Problem** A technician plates a faucet with 0.86 g of Cr metal by electrolysis of aqueous  $\text{Cr}_2(\text{SO}_4)_3$ . If 12.5 min is allowed for the plating, what current is needed?

**Plan** To find the current, we divide charge by time, so we need to find the charge. We write the half-reaction for the  $\text{Cr}^{3+}$  reduction to get the amount (mol) of  $\text{e}^-$  transferred per mole of Cr. To find the charge, we convert the mass of Cr needed (0.86 g) to amount (mol) of Cr. Then, we use the Faraday constant ( $9.65 \times 10^4 \text{ C/mol e}^-$ ) to find the charge and divide by the time (12.5 min, converted to seconds) to obtain the current (see the road map).

**Solution** Writing the balanced half-reaction [ $\text{Cr}_2(\text{SO}_4)_3$  contains the  $\text{Cr}^{3+}$  ion]:

Combining steps to find amount (mol) of  $\text{e}^-$  transferred for the mass of Cr needed:

$$\text{Amount (mol) of e}^- \text{ transferred} = 0.86 \text{ g Cr} \times \frac{1 \text{ mol Cr}}{52.00 \text{ g Cr}} \times \frac{3 \text{ mol e}^-}{1 \text{ mol Cr}} = 0.050 \text{ mol e}^-$$

Calculating the charge using the Faraday constant as a conversion factor between moles of electrons transferred and charge:

$$\text{Charge (C)} = 0.050 \text{ mol e}^- \times \frac{9.65 \times 10^4 \text{ C}}{1 \text{ mol e}^-} = 4.8 \times 10^3 \text{ C}$$

Calculating the current:

$$\text{Current (A)} = \frac{\text{charge (C)}}{\text{time (s)}} = \frac{4.8 \times 10^3 \text{ C}}{12.5 \text{ min}} \times \frac{1 \text{ min}}{60 \text{ s}} = 6.4 \text{ C/s} = \mathbf{6.4 \text{ A}}$$

**Check** Rounding gives

$$(\sim 0.9 \text{ g})(1 \text{ mol Cr}/50 \text{ g})(3 \text{ mol e}^-/1 \text{ mol Cr}) = 5 \times 10^{-2} \text{ mol e}^-$$

Then

$$(5 \times 10^{-2} \text{ mol e}^-)(\sim 1 \times 10^5 \text{ C/mol e}^-) = 5 \times 10^3 \text{ C}$$

and

$$(5 \times 10^3 \text{ C}/12 \text{ min})(1 \text{ min}/60 \text{ s}) = 7 \text{ A}$$

**Comment** In order to introduce Faraday's law, we have neglected some details about actual electroplating. In practice, electroplating chromium has an efficiency of only 30–40% and must be run at a specific temperature range for the plate to appear bright. Nearly 10,000 metric tons ( $2 \times 10^8 \text{ mol}$ ) of chromium are used annually for electroplating.

### FOLLOW-UP PROBLEMS

**21.11A** Using a current of 4.75 A, how many minutes does it take to plate a sculpture with 1.50 g of Cu from a  $\text{CuSO}_4$  solution?

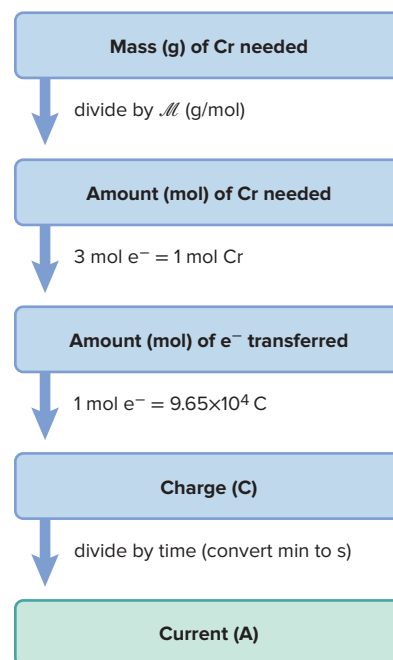

**21.11B** To protect it from corrosion, a section of iron pipe is electrogalvanized with zinc from a basic solution of  $\text{Na}_2\text{Zn}(\text{OH})_4$ . The half-reaction is

If the process takes 8.75 min with a current of 7.03 A, what mass of Zn is deposited on the pipe?

**SOME SIMILAR PROBLEMS** 21.101–21.106

### Road Map

The following Chemical Connections essay links several themes of this chapter to the generation of energy in a living cell.

**B**iological cells apply the principles of electrochemical cells to generate energy. The complex multistep process can be divided into two parts:

1. Bond energy in food generates an electrochemical potential.
2. That potential creates the bond energy of ATP (see Chemical Connections in Chapter 20.)

These steps are part of the *electron-transport chain* (ETC), which lies on the inner membranes of *mitochondria*, the subcellular particles that produce energy (Figure B21.1).

The ETC is a series of large molecules (mostly proteins), each of which contains a *redox couple* (the oxidized and reduced forms of a species), such as  $\text{Fe}^{3+}/\text{Fe}^{2+}$ , that passes electrons along the chain. At three points in this chain, large potential differences supply enough free energy to convert adenosine diphosphate (ADP) into ATP.

### Bond Energy to Electrochemical Potential

Cells utilize the energy in food by releasing it in controlled steps rather than all at once. The reaction that ultimately powers the ETC is the oxidation of hydrogen to form water:  $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$ . But, instead of  $\text{H}_2$  gas, which does not occur in organisms, the hydrogen takes the form of two  $\text{H}^+$  ions and two  $\text{e}^-$ . The biological oxidizing agent  $\text{NAD}^+$  (*nicotinamide adenine dinucleotide*) acquires these protons and electrons in the process of oxidizing molecules in food. To show this process, we use this half-reaction (without canceling an  $\text{H}^+$  on both sides):

At the mitochondrial inner membrane, the  $\text{NADH}$  and  $\text{H}^+$  transfer the two  $\text{e}^-$  to the first redox couple of the ETC and release the two  $\text{H}^+$ . The electrons are transported down the chain of redox couples, where they finally reduce  $\text{O}_2$ . The overall process, with standard electrode potentials,\* is

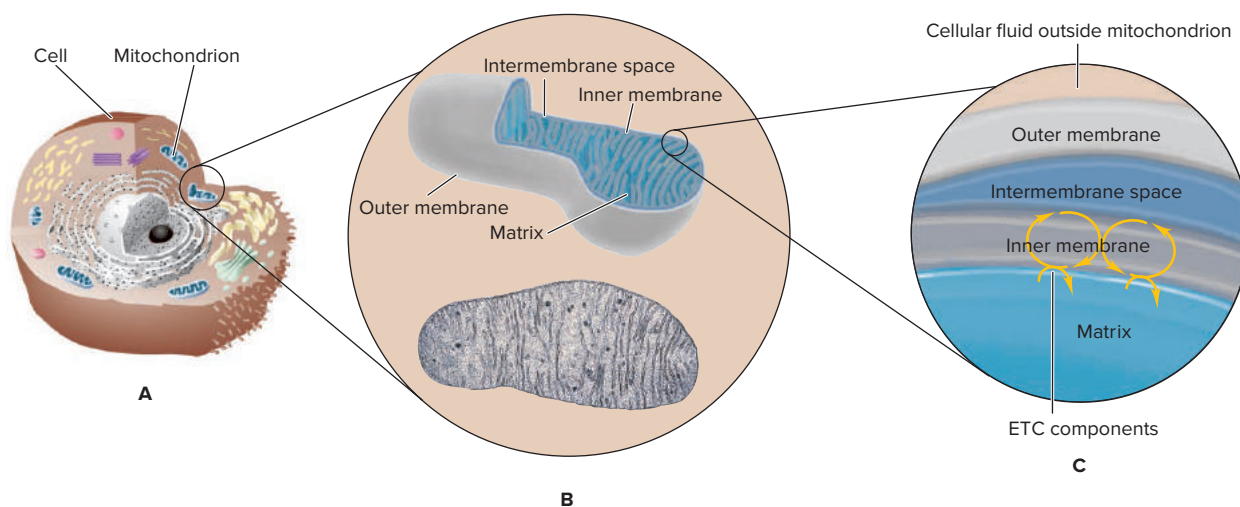

Thus, for every 2 mol of  $\text{e}^-$ , 1 mol of  $\text{NADH}$  enters the ETC, and the free energy equivalent of 1.130 V is available:

$$\begin{aligned} \Delta G^{\circ'} &= -nFE^{\circ'} \\ &= -(2 \text{ mol e}^-/\text{mol NADH})(96.5 \text{ kJ/V}\cdot\text{mol e}^-)(1.130 \text{ V}) \\ &= -218 \text{ kJ/mol NADH} \end{aligned}$$

Note that this aspect of the process functions like a voltaic cell: a spontaneous reaction, the reduction of  $\text{O}_2$  to  $\text{H}_2\text{O}$ , is used to generate a potential. In contrast to the operation of a voltaic cell, this process occurs in many small steps. Figure B21.2 is a highly simplified diagram showing the three steps in the ETC that generate a high enough potential to form ATP from ADP.

Each step consists of several components, in which electrons are passed from one redox couple to the next. Since most of the ETC components are iron-containing proteins, the redox change

\*In biological systems, standard potentials are designated  $E^{\circ'}$  and the standard states include a pH of 7.0 ( $[\text{H}^+] = 1 \times 10^{-7} \text{ M}$ ).

**Figure B21.1** The mitochondrion. **A**, Mitochondria are subcellular particles outside the cell nucleus. **B**, They have a smooth outer membrane and a highly folded inner membrane, shown schematically and in an electron micrograph. **C**, The components of the electron-transport chain are attached to the inner membrane, which is in contact with the matrix, a relatively viscous aqueous mixture of small organic molecules, enzymes, and other macromolecules.

**Figure B21.2** The main energy-yielding steps in the electron-transport chain (ETC). At the three points shown,  $E^\circ$  (or  $\Delta G^\circ$ ) is large enough to form ATP from ADP. (A complex consists of many components; Q is a large organic molecule; Cyt stands for a cytochrome, a protein that contains a metal-ion redox couple.)

consists of the oxidation of  $\text{Fe}^{2+}$  to  $\text{Fe}^{3+}$  in one component accompanied by the reduction of  $\text{Fe}^{3+}$  to  $\text{Fe}^{2+}$  in the other:

In other words, metal ions bound within the ETC proteins are the actual species undergoing the redox reactions.

## Electrochemical Potential to Bond Energy

Formation of ATP requires a lot of energy:

Note that, at each of the three points in Figure B21.2, the free energy *released* exceeds the 30.5 kJ needed to form 1 mol of ATP. Thus, as in an electrolytic cell, an electrochemical potential is supplied to drive a nonspontaneous reaction.

### Problems

- B21.1** In the final steps of the ETC, iron and copper ions in a large protein complex interact with each other.
- Write balanced equations for the one-electron half-reactions of  $\text{Fe}^{3+}$  and of  $\text{Cu}^+$ .
  - Write a balanced overall equation for this redox reaction.

**Figure B21.3** Coupling electron transport to proton transport to ATP synthesis. Electrons are transported along the ETC (curved yellow arrows). Protons pumped into the intermembrane space create an  $[\text{H}^+]$  difference that generates a potential across the inner membrane. When that difference is large enough,  $\text{H}^+$  flows back into the inner space, and the free energy drives the formation of ATP.

We've followed the flow of *electrons* through the ETC. To see how electrochemical potential is converted to bond energy in ATP, we focus on the released *protons*. The free energy released at the three key steps is used to force the  $\text{H}^+$  ions into the intermembrane space; as a result,  $[\text{H}^+]$  of the intermembrane space becomes higher than  $[\text{H}^+]$  of the matrix, the aqueous mixture that fills the spaces between the folds of the inner membrane (Figure B21.3). This part of the process uses the free energy released by the three steps to *create an  $\text{H}^+$  concentration cell across the inner membrane*.

When the  $[\text{H}^+]$  difference across the inner membrane reaches a “trigger” point of about 2.5-fold,  $\text{H}^+$  ions spontaneously flow back through the membrane (in effect, closing the switch and allowing the concentration cell to operate). The free energy released in this spontaneous process drives the nonspontaneous ATP formation via an enzyme-catalyzed mechanism.

Thus, the mitochondrion uses the “electron-motive force” of redox couples on its inner membrane to generate a “proton-motive force” across the membrane, which converts a potential difference into bond energy.

- B21.2** As the ETC proceeds, a difference in  $[\text{H}^+]$  develops across the inner mitochondrial membrane. The “proton-motive force,” which is used to form ATP, is based largely on this difference and is equivalent to an electrical potential of 0.224 V. What is the free energy change (in kJ/mol) associated with the “proton-motive force”?

## › Summary of Section 21.7

- › An electrolytic cell uses electrical energy to drive a nonspontaneous reaction.
- › Oxidation occurs at the anode and reduction at the cathode, but the direction of electron flow and the charges of the electrodes are opposite those in voltaic cells.
- › When two products could form at each electrode, the more easily oxidized substance forms at the anode and the more easily reduced substance forms at the cathode.
- › Overvoltage causes the actual voltage required to be unexpectedly high (especially for producing gases, such as H<sub>2</sub> and O<sub>2</sub>) and can affect the product that forms at each electrode.
- › The amount of product that forms is proportional to the quantity of charge flowing through the cell, which is related to the time the charge flows and the current.
- › Biological redox systems combine aspects of voltaic, concentration, and electrolytic cells to convert bond energy in food into electrochemical potential and then into the bond energy of ATP.

## CHAPTER REVIEW GUIDE

### Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

### Understand These Concepts

1. The meanings of *oxidation* and *reduction*; why an oxidizing agent is reduced and a reducing agent is oxidized (§21.1)
2. How the half-reaction method is used to balance redox reactions in acidic or basic solution (§21.1)
3. The distinction between voltaic and electrolytic cells in terms of the sign of  $\Delta G$  (§21.1)
4. How voltaic cells use a spontaneous reaction to release electrical energy (§21.2)
5. The physical makeup of a voltaic cell: arrangement and composition of half-cells, relative charges of electrodes, and purpose of a salt bridge (§21.2)
6. How the difference in reducing strength of the electrodes determines the direction of electron flow in a voltaic cell (§21.2)
7. The correspondence between a positive  $E_{\text{cell}}$  and a spontaneous cell reaction (§21.3)
8. The usefulness and significance of standard electrode potentials ( $E_{\text{half-cell}}^{\circ}$ ) (§21.3)
9. How  $E_{\text{half-cell}}^{\circ}$  values are combined to give  $E_{\text{cell}}^{\circ}$  (§21.3)
10. How the standard reference electrode is used to find an unknown  $E_{\text{half-cell}}^{\circ}$  (§21.3)
11. How an emf series (e.g., Table 21.2 or Appendix D) is used to write spontaneous redox reactions (§21.3)
12. How the relative reactivity of a metal is determined by its reducing power and is related to the negative of its  $E_{\text{half-cell}}^{\circ}$  (§21.3)
13. How  $E_{\text{cell}}$  (the nonstandard cell potential) is related to  $\Delta G$  (maximum work) and the charge (moles of electrons times the Faraday constant) flowing through the cell (§21.4)
14. The interrelationship of  $\Delta G^{\circ}$ ,  $E_{\text{cell}}^{\circ}$ , and  $K$  (§21.4)
15. How  $E_{\text{cell}}$  changes as the cell operates (as  $Q$  changes) (§21.4)
16. Why a voltaic cell can do work until  $Q = K$  (§21.4)
17. How a concentration cell does work until the half-cell concentrations are equal (§21.4)
18. The distinction between primary (nonrechargeable) and secondary (rechargeable) batteries and the nature of fuel cells (§21.5)

19. How corrosion occurs and is prevented; the similarities between a corroding metal and a voltaic cell (§21.6)
20. How electrolytic cells use nonspontaneous redox reactions driven by an external source of electricity (§21.7)
21. How atomic properties (ionization energy and electronegativity) determine the products of the electrolysis of molten salt mixtures (§21.7)
22. How the electrolysis of water influences the products of aqueous electrolysis; the importance of overvoltage (§21.7)
23. The relationship between the quantity of charge flowing through the cell and the amount of product formed (§21.7)

### Master These Skills

1. Balancing redox reactions by the half-reaction method (§21.1 and SP 21.1)
2. Describing a voltaic cell with a diagram and notation (§21.2 and SP 21.2)
3. Combining  $E_{\text{half-cell}}^{\circ}$  values to obtain  $E_{\text{cell}}^{\circ}$  (§21.3 and SP 21.3)
4. Using  $E_{\text{cell}}^{\circ}$  and a known  $E_{\text{half-cell}}^{\circ}$  to find an unknown  $E_{\text{half-cell}}^{\circ}$  (SP 21.4)
5. Manipulating half-reactions to write a spontaneous redox reaction and calculate its  $E_{\text{cell}}^{\circ}$  (SP 21.5)
6. Ranking the relative strengths of oxidizing and reducing agents in a redox reaction (SP 21.5)
7. Predicting whether a metal can displace hydrogen or another metal from solution (§21.3)
8. Using the interrelationship of  $\Delta G^{\circ}$ ,  $E_{\text{cell}}^{\circ}$ , and  $K$  to calculate two of the three given the third (§21.4 and SP 21.6)
9. Using the Nernst equation to calculate the nonstandard cell potential ( $E_{\text{cell}}$ ) (SP 21.7)
10. Calculating  $E_{\text{cell}}$  of a concentration cell (SP 21.8)
11. Predicting the products of the electrolysis of a mixture of molten salts (SP 21.9)
12. Predicting the products of the electrolysis of aqueous salt solutions (SP 21.10)
13. Calculating the current (or time) needed to produce a given amount of product by electrolysis (SP 21.11)

## Key Terms

Page numbers appear in parentheses.

anode (944)	electrochemical cell (939)	fuel cell (970)	standard electrode (half-cell) potential ( $E_{\text{half-cell}}^{\circ}$ ) (950)
ampere (A) (980)	electrochemistry (939)	half-cell (946)	standard reference half-cell (standard hydrogen electrode) (952)
battery (968)	electrolytic cell (944)	half-reaction method (940)	volt (V) (950)
cathode (944)	electrode (944)	Nernst equation (962)	voltaic (galvanic) cell (944)
cell potential ( $E_{\text{cell}}$ ) (950)	electrolyte (944)	overvoltage (978)	voltage (950)
concentration cell (964)	electromotive force (emf) (950)	salt bridge (947)	
coulomb (C) (950)	electrolysis (976)	standard cell potential ( $E_{\text{cell}}^{\circ}$ ) (950)	
corrosion (972)	Faraday constant ( $F$ ) (959)		

## Key Equations and Relationships

Page numbers appear in parentheses.

**21.1** Relating the spontaneity of a process to the sign of the cell potential (950):

$$E_{\text{cell}} > 0 \text{ for a spontaneous process}$$

**21.2** Relating electric potential to energy and charge in SI units (950):

$$\text{Potential} = \text{energy/charge} \quad \text{or} \quad 1 \text{ V} = 1 \text{ J/C}$$

**21.3** Relating standard cell potential to standard electrode potentials in a voltaic cell (951):

$$E_{\text{cell}}^{\circ} = E_{\text{cathode(reduction)}}^{\circ} - E_{\text{anode(oxidation)}}^{\circ}$$

**21.4** Defining the Faraday constant (960):

$$F = 9.65 \times 10^4 \frac{\text{J}}{\text{V} \cdot \text{mol } e^{-}} \quad (3 \text{ sf})$$

**21.5** Relating the free energy change to the cell potential (960):

$$\Delta G = -nFE_{\text{cell}}$$

**21.6** Finding the standard free energy change from the standard cell potential (960):

$$\Delta G^{\circ} = -nFE_{\text{cell}}^{\circ}$$

**21.7** Finding the equilibrium constant from the standard cell potential (960):

$$E_{\text{cell}}^{\circ} = \frac{RT}{nF} \ln K$$

**21.8** Substituting known values of  $R$ ,  $F$ , and  $T$  into Equation 21.7 and converting to a common logarithm (960):

$$E_{\text{cell}}^{\circ} = \frac{0.0592 \text{ V}}{n} \log K \quad \text{or} \quad \log K = \frac{nE_{\text{cell}}^{\circ}}{0.0592 \text{ V}} \quad (\text{at } 298.15 \text{ K})$$

**21.9** Calculating the nonstandard cell potential (Nernst equation) (962):

$$E_{\text{cell}} = E_{\text{cell}}^{\circ} - \frac{RT}{nF} \ln Q$$

**21.10** Substituting known values of  $R$ ,  $F$ , and  $T$  into the Nernst equation and converting to a common logarithm (962):

$$E_{\text{cell}} = E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q \quad (\text{at } 298.15 \text{ K})$$

**21.11** Relating current to charge and time (980):

$$\text{Current (A)} = \text{charge (C)/time (s)} \quad \text{or} \quad 1 \text{ A} = 1 \text{ C/s}$$

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

**21.2A**

Cell notation:

**21.2B**

Cell notation:

$$\begin{aligned} E_{\text{cell}}^{\circ} &= E_{\text{cathode(reduction)}}^{\circ} - E_{\text{anode(oxidation)}}^{\circ} \\ &= E_{\text{copper}}^{\circ} - E_{\text{silver}}^{\circ} = 0.34 \text{ V} - 0.80 \text{ V} \\ &= -0.46 \text{ V; not spontaneous} \end{aligned}$$

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

(continued)

$$\begin{aligned} E_{\text{cell}}^{\circ} &= E_{\text{cathode}}^{\circ}(\text{reduction}) - E_{\text{anode}}^{\circ}(\text{oxidation}) \\ &= E_{\text{chlorine}}^{\circ} - E_{\text{iron}}^{\circ} = 1.36 \text{ V} - 0.77 \text{ V} \\ &= 0.59 \text{ V}; \text{spontaneous} \end{aligned}$$

$$\begin{aligned} E_{\text{cell}}^{\circ} &= E_{\text{cathode}}^{\circ} - E_{\text{anode}}^{\circ} = E_{\text{bromine}}^{\circ} - E_{\text{vanadium}}^{\circ} \\ E_{\text{vanadium}}^{\circ} &= E_{\text{bromine}}^{\circ} - E_{\text{cell}}^{\circ} = 1.07 \text{ V} - 0.73 \text{ V} = 0.34 \text{ V} \end{aligned}$$

$$\begin{aligned} E_{\text{cell}}^{\circ} &= E_{\text{cathode}}^{\circ} - E_{\text{anode}}^{\circ} = E_{\text{nitrate}}^{\circ} - E_{\text{vanadium}}^{\circ} = 0.62 \text{ V} \\ E_{\text{nitrate}}^{\circ} &= E_{\text{cell}}^{\circ} + E_{\text{vanadium}}^{\circ} = 0.62 \text{ V} + 0.34 \text{ V} = 0.96 \text{ V} \end{aligned}$$

**21.5A** (a) Combine (2) and reversed (1) to obtain equation A:

$$E_{\text{cell}}^{\circ} = 0.61 \text{ V} - 0.34 \text{ V} = 0.27 \text{ V}$$

Combine (1) and reversed (3) to obtain equation B:

$$E_{\text{cell}}^{\circ} = 0.34 \text{ V} - (-1.25 \text{ V}) = 1.59 \text{ V}$$

Combine (2) and reversed (3) to obtain equation C:

$$E_{\text{cell}}^{\circ} = 0.61 \text{ V} - (-1.25 \text{ V}) = 1.86 \text{ V}$$

(b) Oxidizing agents:  $\text{BrO}_3^- > \text{Ag}_2\text{O} > \text{Zn}(\text{OH})_2$

Reducing agents:  $\text{Zn} > \text{Ag} > \text{Br}^-$

$$E_{\text{cell}}^{\circ} = -0.44 \text{ V} - 0.77 \text{ V} = -1.21 \text{ V}$$

The reaction is nonspontaneous. The spontaneous reaction is

Reducing agents:  $\text{Fe} > \text{Fe}^{2+} > \text{Fe}^{3+}$

**21.6A** From Appendix D,

$$E_{\text{cell}}^{\circ} = 0.59 \text{ V} - 0.34 \text{ V} = 0.25 \text{ V}$$

We use Equations 21.6 and 21.8 with  $n = 6 \text{ mol } e^-/\text{mol rxn}$  and

$$E_{\text{cell}}^{\circ} = 0.25 \text{ V}.$$

$$\begin{aligned} \Delta G^{\circ} &= -nFE_{\text{cell}}^{\circ} = -\frac{6 \text{ mol } e^-}{\text{mol rxn}} \times \frac{96.5 \text{ kJ}}{\text{V}\cdot\text{mol } e^-} \times 0.25 \text{ V} \\ &= -1.4 \times 10^2 \text{ kJ/mol rxn} \end{aligned}$$

$$E_{\text{cell}}^{\circ} = 0.25 \text{ V} = \frac{0.0592 \text{ V}}{n} \log K$$

$$\log K = \frac{0.25 \text{ V} \times 6}{0.0592 \text{ V}} = 25.34; K = 10^{25.34} = 2.2 \times 10^{25}$$

$$\Delta G^{\circ} = -RT \ln K$$

$$\ln K = -\frac{\Delta G^{\circ}}{RT} = -\frac{-1.43 \times 10^5 \text{ J/mol rxn}}{8.314 \text{ J/mol rxn}\cdot\text{K} \times 298 \text{ K}} = 57.72$$

$$K = e^{57.72} = 1.2 \times 10^{25}$$

$$E_{\text{cell}}^{\circ} = \frac{0.0592 \text{ V}}{n} \log K = \frac{0.0592 \text{ V}}{2} \log (1.2 \times 10^{25}) = 0.742 \text{ V}$$

**21.7A** From Appendix D,

$$E_{\text{cell}}^{\circ} = -0.14 \text{ V} - (-0.74 \text{ V}) = 0.60 \text{ V}; n = 6 \text{ mol } e^-/\text{mol rxn}$$

$$Q = \frac{[\text{Cr}^{3+}]^2}{[\text{Sn}^{2+}]^3} = \frac{(1.60)^2}{(0.20)^3} = 320$$

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q = 0.60 \text{ V} - \frac{0.0592 \text{ V}}{6} \log 320 \\ &= 0.58 \text{ V} \end{aligned}$$

**21.7B** From Appendix D,

So,  $E_{\text{cell}}^{\circ} = 0.34 \text{ V} - (-0.44 \text{ V}) = 0.78 \text{ V}$

Therefore,  $E_{\text{cell}} = 0.78 \text{ V} + 0.25 \text{ V} = 1.03 \text{ V}; n = 2 \text{ mol } e^-/\text{mol rxn}$ .

$$E_{\text{cell}} = E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q$$

$$1.03 \text{ V} = 0.78 \text{ V} - \frac{0.0592 \text{ V}}{2} \log \frac{[\text{Fe}^{2+}]}{[0.30]}$$

$$-8.45 = \log \frac{[\text{Fe}^{2+}]}{[0.30]}$$

$$10^{-8.45} = 3.6 \times 10^{-9} = \frac{[\text{Fe}^{2+}]}{[0.30]}$$

$$[\text{Fe}^{2+}] = 3.6 \times 10^{-9} \times 0.30 \text{ M} = 1.1 \times 10^{-9} \text{ M}$$

**21.8A** The cell reaction is

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log \frac{[\text{Ni}^{2+}]_{\text{dil}}}{[\text{Ni}^{2+}]_{\text{conc}}} \\ &= 0 \text{ V} - \frac{0.0592 \text{ V}}{2} \log \frac{0.015}{0.40} = 0.042 \text{ V} \end{aligned}$$

**21.8B** The cell reaction is

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log \frac{[\text{Au}^{3+}]_{\text{dil}}}{[\text{Au}^{3+}]_{\text{conc}}} \\ &= 0 \text{ V} - \frac{0.0592 \text{ V}}{3} \log \frac{7.0 \times 10^{-4}}{2.5 \times 10^{-2}} = 0.031 \text{ V} \end{aligned}$$

In a concentration cell, the anode half-cell contains the more dilute solution, which is the solution in half-cell A. Since the anode has the negative charge, the electrode in A is negative.

**21.9A** Oxidizing agents:  $\text{Cs}^+$  and  $\text{Li}^+$ . Li, at the top of Group 1A(1), has a higher IE, so it is more easily reduced:

Reducing agents:  $\text{F}^-$  and  $\text{I}^-$ . I, near the bottom of Group 7A(17), has a lower EN, so it is more easily oxidized:

**21.9B** Oxidizing agents:  $\text{K}^+$  and  $\text{Al}^{3+}$ . Al is above and to the right of K in the periodic table, so it has a higher IE:

Reducing agents:  $\text{F}^-$  and  $\text{Br}^-$ . Br is below F in Group 7A(17), so it has a lower EN:

**21.10A** The possible reduction (cathode) half-reactions are

The possible oxidation (anode) half-reactions are

Thus,  $\text{Pb}^{2+}$  is reduced and Pb forms at the cathode, and  $\text{H}_2\text{O}$  is oxidized and  $\text{O}_2$  forms at the anode.

**21.10B** The possible reduction (cathode) half-reaction are

$$\text{Au}^{3+}(aq) + 3\text{e}^- \longrightarrow \text{Au}(s) \quad E^\circ = 1.50 \text{ V} \quad [\text{cathode; reduction}]$$

Since  $\text{Au}^{3+}$  has the more positive reduction potential, Au forms at the cathode.

Because of overvoltage,  $\text{O}_2$  will not form at the anode, so  $\text{Br}_2$  will form:

**21.11A**  $\text{Cu}^{2+}(aq) + 2\text{e}^- \longrightarrow \text{Cu}(s)$ ; therefore,  
 $2 \text{ mol e}^- / 1 \text{ mol Cu} = 2 \text{ mol e}^- / 63.55 \text{ g Cu}$

$$\begin{aligned} \text{Time (min)} &= 1.50 \text{ g Cu} \times \frac{2 \text{ mol e}^-}{63.55 \text{ g Cu}} \\ &\quad \times \frac{9.65 \times 10^4 \text{ C}}{1 \text{ mol e}^-} \times \frac{1 \text{ s}}{4.75 \text{ C}} \times \frac{1 \text{ min}}{60 \text{ s}} \\ &= 16.0 \text{ min} \end{aligned}$$

**21.11B** The half-reaction shows  $2 \text{ mol e}^- / 1 \text{ mol Zn}$ . Thus,

$$\text{Charge (C)} = 8.75 \text{ min} \times \frac{60 \text{ s}}{1 \text{ min}} \times \frac{7.03 \text{ C}}{\text{s}} = 3691 \text{ C}$$

$$\begin{aligned} \text{Mass (g) of Zn} &= 3691 \text{ C} \times \frac{1 \text{ mol e}^-}{9.65 \times 10^4 \text{ C}} \times \frac{1 \text{ mol Zn}}{2 \text{ mol e}^-} \times \frac{65.38 \text{ g Zn}}{1 \text{ mol Zn}} \\ &= 1.25 \text{ g Zn} \end{aligned}$$

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

**Note:** Unless stated otherwise, all problems refer to systems at 298 K (25°C).

### Redox Reactions and Electrochemical Cells

(Sample Problem 21.1)

#### Concept Review Questions

**21.1** Define *oxidation* and *reduction* in terms of electron transfer and change in oxidation number.

**21.2** Why must an electrochemical process involve a redox reaction?

**21.3** Can one half-reaction in a redox process take place independently of the other? Explain.

**21.4** Water is used to balance O atoms in the half-reaction method. Why can't  $\text{O}^{2-}$  ions be used instead?

**21.5** During the redox balancing process, what step is taken to ensure that  $\text{e}^-$  lost equals  $\text{e}^-$  gained?

**21.6** How are protons removed when balancing a redox reaction in basic solution?

**21.7** Are spectator ions used to balance the half-reactions of a redox reaction? At what stage might spectator ions enter the balancing process?

**21.8** Which type of electrochemical cell has  $\Delta G_{\text{sys}} < 0$ ? Which type shows an increase in free energy?

**21.9** Which statements are true? Correct any that are false.

- In a voltaic cell, the anode is negative relative to the cathode.
- Oxidation occurs at the anode of a voltaic or electrolytic cell.
- Electrons flow into the cathode of an electrolytic cell.
- In a voltaic cell, the surroundings do work on the system.
- A metal that plates out of an electrolytic cell appears on the cathode.
- In an electrochemical cell, the electrolyte provides a solution of mobile electrons.

#### Skill-Building Exercises (grouped in similar pairs)

**21.10** Consider the following balanced redox reaction:

- Which species is being oxidized?
- Which species is being reduced?
- Which species is the oxidizing agent?
- Which species is the reducing agent?
- From which species to which does electron transfer occur?
- Write the balanced molecular equation, with  $\text{K}^+$  and  $\text{SO}_4^{2-}$  as the spectator ions.

**21.11** Consider the following balanced redox reaction:

- Which species is being oxidized?
- Which species is being reduced?
- Which species is the oxidizing agent?

- (d) Which species is the reducing agent?  
 (e) From which species to which does electron transfer occur?  
 (f) Write the balanced molecular equation, with  $\text{Na}^+$  as the spectator ion.

**21.12** Balance the following skeleton reactions and identify the oxidizing and reducing agents:

- (a)  $\text{ClO}_3^-(aq) + \text{I}^-(aq) \longrightarrow \text{I}_2(s) + \text{Cl}^-(aq)$  [acidic]  
 (b)  $\text{MnO}_4^-(aq) + \text{SO}_3^{2-}(aq) \longrightarrow \text{MnO}_2(s) + \text{SO}_4^{2-}(aq)$  [basic]  
 (c)  $\text{MnO}_4^-(aq) + \text{H}_2\text{O}_2(aq) \longrightarrow \text{Mn}^{2+}(aq) + \text{O}_2(g)$  [acidic]

**21.13** Balance the following skeleton reactions and identify the oxidizing and reducing agents:

- (a)  $\text{O}_2(g) + \text{NO}(g) \longrightarrow \text{NO}_3^-(aq)$  [acidic]  
 (b)  $\text{CrO}_4^{2-}(aq) + \text{Cu}(s) \longrightarrow \text{Cr}(\text{OH})_3(s) + \text{Cu}(\text{OH})_2(s)$  [basic]  
 (c)  $\text{AsO}_4^{3-}(aq) + \text{NO}_2^-(aq) \longrightarrow \text{AsO}_2^-(aq) + \text{NO}_3^-(aq)$  [basic]

**21.14** Balance the following skeleton reactions and identify the oxidizing and reducing agents:

- (a)  $\text{Cr}_2\text{O}_7^{2-}(aq) + \text{Zn}(s) \longrightarrow \text{Zn}^{2+}(aq) + \text{Cr}^{3+}(aq)$  [acidic]  
 (b)  $\text{Fe}(\text{OH})_2(s) + \text{MnO}_4^-(aq) \longrightarrow \text{MnO}_2(s) + \text{Fe}(\text{OH})_3(s)$  [basic]  
 (c)  $\text{Zn}(s) + \text{NO}_3^-(aq) \longrightarrow \text{Zn}^{2+}(aq) + \text{N}_2(g)$  [acidic]

**21.15** Balance the following skeleton reactions and identify the oxidizing and reducing agents:

- (a)  $\text{BH}_4^-(aq) + \text{ClO}_3^-(aq) \longrightarrow \text{H}_2\text{BO}_3^-(aq) + \text{Cl}^-(aq)$  [basic]  
 (b)  $\text{CrO}_4^{2-}(aq) + \text{N}_2\text{O}(g) \longrightarrow \text{Cr}^{3+}(aq) + \text{NO}(g)$  [acidic]  
 (c)  $\text{Br}_2(l) \longrightarrow \text{BrO}_3^-(aq) + \text{Br}^-(aq)$  [basic]

**21.16** Balance the following skeleton reactions and identify the oxidizing and reducing agents:

- (a)  $\text{Sb}(s) + \text{NO}_3^-(aq) \longrightarrow \text{Sb}_2\text{O}_3(s) + \text{NO}(g)$  [acidic]  
 (b)  $\text{Mn}^{2+}(aq) + \text{BiO}_3^-(aq) \longrightarrow \text{MnO}_4^-(aq) + \text{Bi}^{3+}(aq)$  [acidic]  
 (c)  $\text{Fe}(\text{OH})_2(s) + \text{Pb}(\text{OH})_3^-(aq) \longrightarrow \text{Fe}(\text{OH})_3(s) + \text{Pb}(s)$  [basic]

**21.17** Balance the following skeleton reactions and identify the oxidizing and reducing agents:

- (a)  $\text{NO}_2(g) \longrightarrow \text{NO}_3^-(aq) + \text{NO}_2^-(aq)$  [basic]  
 (b)  $\text{Zn}(s) + \text{NO}_3^-(aq) \longrightarrow \text{Zn}(\text{OH})_4^{2-}(aq) + \text{NH}_3(g)$  [basic]  
 (c)  $\text{H}_2\text{S}(g) + \text{NO}_3^-(aq) \longrightarrow \text{S}_8(s) + \text{NO}(g)$  [acidic]

**21.18** Balance the following skeleton reactions and identify the oxidizing and reducing agents:

- (a)  $\text{As}_4\text{O}_6(s) + \text{MnO}_4^-(aq) \longrightarrow \text{AsO}_4^{3-}(aq) + \text{Mn}^{2+}(aq)$  [acidic]  
 (b)  $\text{P}_4(s) \longrightarrow \text{HPO}_3^{2-}(aq) + \text{PH}_3(g)$  [acidic]  
 (c)  $\text{MnO}_4^-(aq) + \text{CN}^-(aq) \longrightarrow \text{MnO}_2(s) + \text{CNO}^-(aq)$  [basic]

**21.19** Balance the following skeleton reactions and identify the oxidizing and reducing agents:

- (a)  $\text{SO}_3^{2-}(aq) + \text{Cl}_2(g) \longrightarrow \text{SO}_4^{2-}(aq) + \text{Cl}^-(aq)$  [basic]  
 (b)  $\text{Fe}(\text{CN})_6^{3-}(aq) + \text{Re}(s) \longrightarrow \text{Fe}(\text{CN})_6^{4-}(aq) + \text{ReO}_4^-(aq)$  [basic]  
 (c)  $\text{MnO}_4^-(aq) + \text{HCOOH}(aq) \longrightarrow \text{Mn}^{2+}(aq) + \text{CO}_2(g)$  [acidic]

### Problems in Context

**21.20** In many residential water systems, the aqueous  $\text{Fe}^{3+}$  concentration is high enough to stain sinks and turn drinking water light brown. The iron content is analyzed by first reducing the  $\text{Fe}^{3+}$  to  $\text{Fe}^{2+}$  and then titrating with  $\text{MnO}_4^-$  in acidic solution. Balance the skeleton reaction of the titration step:

**21.21** *Aqua regia*, a mixture of concentrated  $\text{HNO}_3$  and  $\text{HCl}$ , was developed by alchemists as a means to “dissolve” gold. The process is a redox reaction with this simplified skeleton reaction:

- (a) Balance the reaction by the half-reaction method.  
 (b) What are the oxidizing and reducing agents?  
 (c) What is the function of  $\text{HCl}$  in *aqua regia*?

### Voltaic Cells: Using Spontaneous Reactions to Generate Electrical Energy

(Sample Problem 21.2)

#### Concept Review Questions

**21.22** Consider the following general voltaic cell:

Identify the following:

- (a) Anode  
 (b) Cathode  
 (c) Salt bridge  
 (d) Electrode from which  $e^-$  leave the cell  
 (e) Electrode with a positive charge  
 (f) Electrode that gains mass as the cell operates (assuming that a metal plates out)

**21.23** Why does a voltaic cell not operate unless the two compartments are connected through an external circuit?

**21.24** What purpose does the salt bridge serve in a voltaic cell, and how does it accomplish this purpose?

**21.25** What is the difference between an active and an inactive electrode? Why are inactive electrodes used? Name two substances commonly used for inactive electrodes.

**21.26** When a piece of metal A is placed in a solution containing ions of metal B, metal B plates out on the piece of A.

- (a) Which metal is being oxidized?  
 (b) Which metal is being displaced?  
 (c) Which metal would you use as the anode in a voltaic cell incorporating these two metals?  
 (d) If bubbles of  $\text{H}_2$  form when B is placed in acid, will they form if A is placed in acid? Explain.

### Skill-Building Exercises (grouped in similar pairs)

**21.27** Consider the following voltaic cell:

- (a) In which direction do electrons flow in the external circuit?  
 (b) In which half-cell does oxidation occur?  
 (c) In which half-cell do electrons enter the cell?

- (d) At which electrode are electrons consumed?  
 (e) Which electrode is negatively charged?  
 (f) Which electrode decreases in mass during cell operation?  
 (g) Suggest a solution for the electrolyte in the cathode compartment.  
 (h) Suggest a pair of ions for the salt bridge.  
 (i) For which electrode could you use an inactive material?  
 (j) In which direction do anions within the salt bridge move to maintain charge neutrality?  
 (k) Write balanced half-reactions and the overall cell reaction.

**21.28** Consider the following voltaic cell:

- (a) In which direction do electrons flow in the external circuit?  
 (b) In which half-cell does reduction occur?  
 (c) In which half-cell do electrons leave the cell?  
 (d) At which electrode are electrons generated?  
 (e) Which electrode is positively charged?  
 (f) Which electrode increases in mass during cell operation?  
 (g) Suggest a solution for the electrolyte in the anode compartment.  
 (h) Suggest a pair of ions for the salt bridge.  
 (i) For which electrode could you use an inactive material?  
 (j) In which direction do cations within the salt bridge move to maintain charge neutrality?  
 (k) Write balanced half-reactions and the overall cell reaction.

**21.29** A voltaic cell is constructed with an Sn/Sn<sup>2+</sup> half-cell and a Zn/Zn<sup>2+</sup> half-cell. The zinc electrode is negative.

- (a) Write balanced half-reactions and the overall cell reaction.  
 (b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.

**21.30** A voltaic cell is constructed with an Ag/Ag<sup>+</sup> half-cell and a Pb/Pb<sup>2+</sup> half-cell. The silver electrode is positive.

- (a) Write balanced half-reactions and the overall cell reaction.  
 (b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.

**21.31** A voltaic cell is constructed with an Fe/Fe<sup>2+</sup> half-cell and an Mn/Mn<sup>2+</sup> half-cell. The iron electrode is positive.

- (a) Write balanced half-reactions and the overall cell reaction.  
 (b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.

**21.32** A voltaic cell is constructed with a Cu/Cu<sup>2+</sup> half-cell and an Ni/Ni<sup>2+</sup> half-cell. The nickel electrode is negative.

- (a) Write balanced half-reactions and the overall cell reaction.  
 (b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.

**21.33** Write the cell notation for the voltaic cell that incorporates each of the following redox reactions:

**21.34** Write a balanced equation from each cell notation:

### Cell Potential: Output of a Voltaic Cell

(Sample Problems 21.3 to 21.5)

### Concept Review Questions

**21.35** How is a standard reference electrode used to determine unknown  $E_{\text{half-cell}}^\circ$  values?

**21.36** What does a negative  $E_{\text{cell}}^\circ$  indicate about a redox reaction? What does it indicate about the reverse reaction?

**21.37** The standard cell potential is a thermodynamic state function. How are  $E^\circ$  values treated similarly to  $\Delta H^\circ$ ,  $\Delta G^\circ$ , and  $S^\circ$  values? How are they treated differently?

### Skill-Building Exercises (grouped in similar pairs)

**21.38** In basic solution, Se<sup>2-</sup> and SO<sub>3</sub><sup>2-</sup> ions react spontaneously:

(a) Write balanced half-reactions for the process.

(b) If  $E_{\text{sulfite}}^\circ$  is  $-0.57 \text{ V}$ , calculate  $E_{\text{selenium}}^\circ$ .

**21.39** In acidic solution, O<sub>3</sub> and Mn<sup>2+</sup> ions react spontaneously:

(a) Write the balanced half-reactions.

(b) Using Appendix D to find  $E_{\text{ozone}}^\circ$ , calculate  $E_{\text{manganese}}^\circ$ .

**21.40** Use the emf series (Appendix D) to arrange each set of species.

(a) In order of *decreasing* strength as *oxidizing* agents: Fe<sup>3+</sup>, Br<sub>2</sub>, Cu<sup>2+</sup>

(b) In order of *increasing* strength as *oxidizing* agents: Ca<sup>2+</sup>, Cr<sub>2</sub>O<sub>7</sub><sup>2-</sup>, Ag<sup>+</sup>

**21.41** Use the emf series (Appendix D) to arrange each set of species.

(a) In order of *decreasing* strength as *reducing* agents: SO<sub>2</sub>, PbSO<sub>4</sub>, MnO<sub>2</sub>

(b) In order of *increasing* strength as *reducing* agents: Hg, Fe, Sn

**21.42** Balance each skeleton reaction, use Appendix D to calculate  $E_{\text{cell}}^\circ$ , and state whether the reaction is spontaneous:

**21.43** Balance each skeleton reaction, use Appendix D to calculate  $E_{\text{cell}}^\circ$ , and state whether the reaction is spontaneous:

**21.44** Balance each skeleton reaction, use Appendix D to calculate  $E_{\text{cell}}^\circ$ , and state whether the reaction is spontaneous:

**21.45** Balance each skeleton reaction, use Appendix D to calculate  $E_{\text{cell}}^{\circ}$ , and state whether the reaction is spontaneous:

**21.46** Use the following half-reactions to write three spontaneous reactions, calculate  $E_{\text{cell}}^{\circ}$  for each reaction, and rank the strengths of the oxidizing and reducing agents:

**21.47** Use the following half-reactions to write three spontaneous reactions, calculate  $E_{\text{cell}}^{\circ}$  for each reaction, and rank the strengths of the oxidizing and reducing agents:

**21.48** Use the following half-reactions to write three spontaneous reactions, calculate  $E_{\text{cell}}^{\circ}$  for each reaction, and rank the strengths of the oxidizing and reducing agents:

**21.49** Use the following half-reactions to write three spontaneous reactions, calculate  $E_{\text{cell}}^{\circ}$  for each reaction, and rank the strengths of the oxidizing and reducing agents:

### Problems in Context

**21.50** When metal A is placed in a solution of a salt of metal B, the surface of metal A changes color. When metal B is placed in acid solution, gas bubbles form on the surface of the metal. When metal A is placed in a solution of a salt of metal C, no change is observed in the solution or on the surface of metal A.

- (a) Will metal C cause formation of  $\text{H}_2$  when placed in acid solution?  
 (b) Rank metals A, B, and C in order of *decreasing* reducing strength.

**21.51** When a clean iron nail is placed in an aqueous solution of copper(II) sulfate, the nail becomes coated with a brownish-black material.

- (a) What is the material coating the iron?  
 (b) What are the oxidizing and reducing agents?  
 (c) Can this reaction be made into a voltaic cell?  
 (d) Write the balanced equation for the reaction.  
 (e) Calculate  $E_{\text{cell}}^{\circ}$  for the process.

### Free Energy and Electrical Work

(Sample Problems 21.6 to 21.8)

### Concept Review Questions

- 21.52** (a) How do the relative magnitudes of  $Q$  and  $K$  relate to the signs of  $\Delta G$  and  $E_{\text{cell}}$ ? Explain.  
 (b) Can a cell do work when  $Q/K > 1$  or  $Q/K < 1$ ? Explain.

**21.53** A voltaic cell consists of  $A/A^+$  and  $B/B^+$  half-cells, where A and B are metals and the A electrode is negative. The initial  $[A^+]/[B^+]$  is such that  $E_{\text{cell}} > E_{\text{cell}}^{\circ}$ .

- (a) How do  $[A^+]$  and  $[B^+]$  change as the cell operates?  
 (b) How does  $E_{\text{cell}}$  change as the cell operates?  
 (c) What is  $[A^+]/[B^+]$  when  $E_{\text{cell}} = E_{\text{cell}}^{\circ}$ ? Explain.  
 (d) Is it possible for  $E_{\text{cell}}$  to be less than  $E_{\text{cell}}^{\circ}$ ? Explain.

**21.54** Explain whether  $E_{\text{cell}}$  of a voltaic cell will increase or decrease with each of the following changes:

- (a) Decrease in cell temperature  
 (b) Increase in [active ion] in the anode compartment  
 (c) Increase in [active ion] in the cathode compartment  
 (d) Increase in pressure of a gaseous reactant in the cathode compartment

**21.55** In a concentration cell, is the more concentrated electrolyte in the cathode or the anode compartment? Explain.

### Skill-Building Exercises (grouped in similar pairs)

**21.56** What is the value of the equilibrium constant for the reaction between each pair at  $25^{\circ}\text{C}$ ?

**21.57** What is the value of the equilibrium constant for the reaction between each pair at  $25^{\circ}\text{C}$ ?

**21.58** What is the value of the equilibrium constant for the reaction between each pair at  $25^{\circ}\text{C}$ ?

**21.59** What is the value of the equilibrium constant for the reaction between each pair at  $25^{\circ}\text{C}$ ?

**21.60** Calculate  $\Delta G^{\circ}$  for each of the reactions in Problem 21.56.

**21.61** Calculate  $\Delta G^{\circ}$  for each of the reactions in Problem 21.57.

**21.62** Calculate  $\Delta G^{\circ}$  for each of the reactions in Problem 21.58.

**21.63** Calculate  $\Delta G^{\circ}$  for each of the reactions in Problem 21.59.

**21.64** What are  $E_{\text{cell}}^{\circ}$  and  $\Delta G^{\circ}$  of a redox reaction at  $25^{\circ}\text{C}$  for which  $n = 1$  and  $K = 5.0 \times 10^4$ ?

**21.65** What are  $E_{\text{cell}}^{\circ}$  and  $\Delta G^{\circ}$  of a redox reaction at  $25^{\circ}\text{C}$  for which  $n = 1$  and  $K = 5.0 \times 10^{-6}$ ?

**21.66** What are  $E_{\text{cell}}^{\circ}$  and  $\Delta G^{\circ}$  of a redox reaction at  $25^{\circ}\text{C}$  for which  $n = 2$  and  $K = 65$ ?

**21.67** What are  $E_{\text{cell}}^{\circ}$  and  $\Delta G^{\circ}$  of a redox reaction at  $25^{\circ}\text{C}$  for which  $n = 2$  and  $K = 0.065$ ?

**21.68** A voltaic cell consists of a standard reference half-cell and a  $\text{Cu}/\text{Cu}^{2+}$  half-cell. Calculate  $[\text{Cu}^{2+}]$  when  $E_{\text{cell}}$  is  $0.22 \text{ V}$ .

**21.69** A voltaic cell consists of an  $\text{Mn}/\text{Mn}^{2+}$  half-cell and a  $\text{Pb}/\text{Pb}^{2+}$  half-cell. Calculate  $[\text{Pb}^{2+}]$  when  $[\text{Mn}^{2+}]$  is  $1.4 \text{ M}$  and  $E_{\text{cell}}$  is  $0.44 \text{ V}$ .

**21.70** A voltaic cell with  $\text{Ni}/\text{Ni}^{2+}$  and  $\text{Co}/\text{Co}^{2+}$  half-cells has the following initial concentrations:  $[\text{Ni}^{2+}] = 0.80 \text{ M}$ ;  $[\text{Co}^{2+}] = 0.20 \text{ M}$ .

- (a) What is the initial  $E_{\text{cell}}$ ?  
 (b) What is  $[\text{Ni}^{2+}]$  when  $E_{\text{cell}}$  reaches  $0.03 \text{ V}$ ?  
 (c) What are the equilibrium concentrations of the ions?

**21.71** A voltaic cell with  $\text{Mn}/\text{Mn}^{2+}$  and  $\text{Cd}/\text{Cd}^{2+}$  half-cells has the following initial concentrations:  $[\text{Mn}^{2+}] = 0.090 \text{ M}$ ;  $[\text{Cd}^{2+}] = 0.060 \text{ M}$ .

- (a) What is the initial  $E_{\text{cell}}$ ?  
 (b) What is  $E_{\text{cell}}$  when  $[\text{Cd}^{2+}]$  reaches  $0.050\text{ M}$ ?  
 (c) What is  $[\text{Mn}^{2+}]$  when  $E_{\text{cell}}$  reaches  $0.055\text{ V}$ ?  
 (d) What are the equilibrium concentrations of the ions?

**21.72** A voltaic cell consists of two  $\text{H}_2/\text{H}^+$  half-cells. Half-cell A has  $\text{H}_2$  at  $0.95\text{ atm}$  bubbling into  $0.10\text{ M HCl}$ . Half-cell B has  $\text{H}_2$  at  $0.60\text{ atm}$  bubbling into  $2.0\text{ M HCl}$ . Which half-cell houses the anode? What is the voltage of the cell?

**21.73** A voltaic cell consists of two  $\text{Sn}/\text{Sn}^{2+}$  half-cells, A and B. The electrolyte in A is  $0.13\text{ M Sn}(\text{NO}_3)_2$ . The electrolyte in B is  $0.87\text{ M Sn}(\text{NO}_3)_2$ . Which half-cell houses the cathode? What is the voltage of the cell?

### Electrochemical Processes in Batteries

#### Concept Review Questions

**21.74** What is the direction of electron flow with respect to the anode and the cathode in a battery? Explain.

**21.75** In the everyday batteries used in flashlights, toys, and so forth, no salt bridge is evident. What is used in these cells to separate the anode and cathode compartments?

**21.76** Both a D-sized and an AAA-sized alkaline battery have an output of  $1.5\text{ V}$ . What property of the cell potential allows this to occur? What is different about these two batteries?

#### Problems in Context

**21.77** Many common electrical devices require the use of more than one battery.

- (a) How many alkaline batteries must be placed in series to light a flashlight with a  $6.0\text{-V}$  bulb?  
 (b) What is the voltage requirement of a camera that uses six silver batteries?  
 (c) How many volts can a car battery deliver if two of its anode/cathode cells are shorted?

### Corrosion: An Environmental Voltaic Cell

#### Concept Review Questions

**21.78** During reconstruction of the Statue of Liberty, Teflon spacers were placed between the iron skeleton and the copper plates that cover the statue. What purpose do these spacers serve?

**21.79** Why do steel bridge-supports rust at the waterline but not above or below it?

**21.80** After the 1930s, chromium replaced nickel for corrosion resistance and appearance on car bumpers and trim. How does chromium protect steel from corrosion?

**21.81** Which of the following metals are suitable for use as sacrificial anodes to protect against corrosion of underground iron pipes? If any are not suitable, explain why:

- (a) Aluminum (b) Magnesium (c) Sodium (d) Lead  
 (e) Nickel (f) Zinc (g) Chromium

### Electrolytic Cells: Using Electrical Energy to Drive Nonspontaneous Reactions

(Sample Problems 21.9 to 21.11)

#### Concept Review Questions

**Note:** Unless stated otherwise, assume that the electrolytic cells in the following problems operate at 100% efficiency.

**21.82** Consider the following general electrolytic cell:

- (a) At which electrode does oxidation occur?  
 (b) At which electrode does elemental M form?  
 (c) At which electrode are electrons being released by ions?  
 (d) At which electrode are electrons entering the cell?

**21.83** A voltaic cell consists of  $\text{Cr}/\text{Cr}^{3+}$  and  $\text{Cd}/\text{Cd}^{2+}$  half-cells with all components in their standard states. After 10 minutes of operation, a thin coating of cadmium metal has plated out on the cathode. Describe what will happen if you attach the negative terminal of a dry cell ( $1.5\text{ V}$ ) to the cathode and the positive terminal to the anode.

**21.84** Why are  $E_{\text{half-cell}}$  values for the oxidation and reduction of water different from  $E_{\text{half-cell}}^{\circ}$  values for the same processes?

**21.85** In an aqueous electrolytic cell, nitrate ions never react at the anode, but nitrite ions do. Explain.

**21.86** How does overvoltage influence the products in the electrolysis of aqueous salts?

### Skill-Building Exercises (grouped in similar pairs)

**21.87** In the electrolysis of molten  $\text{NaBr}$ :

- (a) What product forms at the anode?  
 (b) What product forms at the cathode?

**21.88** In the electrolysis of molten  $\text{BaI}_2$ :

- (a) What product forms at the negative electrode?  
 (b) What product forms at the positive electrode?

**21.89** In the electrolysis of a molten mixture of  $\text{KI}$  and  $\text{MgF}_2$ , identify the product that forms at the anode and at the cathode.

**21.90** In the electrolysis of a molten mixture of  $\text{CsBr}$  and  $\text{SrCl}_2$ , identify the product that forms at the negative electrode and at the positive electrode.

**21.91** In the electrolysis of a molten mixture of  $\text{NaCl}$  and  $\text{CaBr}_2$ , identify the product that forms at the anode and at the cathode.

**21.92** In the electrolysis of a molten mixture of  $\text{RbF}$  and  $\text{CaCl}_2$ , identify the product that forms at the negative electrode and at the positive electrode.

**21.93** Which of the following elements can be prepared by electrolysis of their aqueous salts: copper, barium, aluminum, bromine?

**21.94** Which of the following elements can be prepared by electrolysis of their aqueous salts: strontium, gold, tin, chlorine?

**21.95** Which of the following elements can be prepared by electrolysis of their aqueous salts: lithium, iodine, zinc, silver?

**21.96** Which of the following elements can be prepared by electrolysis of their aqueous salts: fluorine, manganese, iron, cadmium?

**21.97** Write a balanced half-reaction for the product that forms at each electrode in the aqueous electrolysis of the following salts:

(a) LiF; (b) SnSO<sub>4</sub>.

**21.98** Write a balanced half-reaction for the product that forms at each electrode in the aqueous electrolysis of the following salts:

(a) ZnBr<sub>2</sub>; (b) Cu(HCO<sub>3</sub>)<sub>2</sub>.

**21.99** Write a balanced half-reaction for the product that forms at each electrode in the aqueous electrolysis of the following salts:

(a) Cr(NO<sub>3</sub>)<sub>3</sub>; (b) MnCl<sub>2</sub>.

**21.100** Write a balanced half-reaction for the product that forms at each electrode in the aqueous electrolysis of the following salts:

(a) FeI<sub>2</sub>; (b) K<sub>3</sub>PO<sub>4</sub>.

**21.101** Electrolysis of molten MgCl<sub>2</sub> is the final production step in the isolation of magnesium from seawater by the Dow process (Section 22.4). Assuming that 45.6 g of Mg metal forms:

(a) How many moles of electrons are required?

(b) How many coulombs are required?

(c) How many amps will produce this amount in 3.50 h?

**21.102** Electrolysis of molten NaCl in a Downs cell is the major isolation step in the production of sodium metal (Section 22.4). Assuming that 215 g of Na metal forms:

(a) How many moles of electrons are required?

(b) How many coulombs are required?

(c) How many amps will produce this amount in 9.50 h?

**21.103** How many grams of radium can form by passing 235 C through an electrolytic cell containing a molten radium salt?

**21.104** How many grams of aluminum can form by passing 305 C through an electrolytic cell containing a molten aluminum salt?

**21.105** How many seconds does it take to deposit 65.5 g of Zn on a steel gate when 21.0 A is passed through a ZnSO<sub>4</sub> solution?

**21.106** How many seconds does it take to deposit 1.63 g of Ni on a decorative drawer handle when 13.7 A is passed through a Ni(NO<sub>3</sub>)<sub>2</sub> solution?

### Problems in Context

**21.107** A professor adds Na<sub>2</sub>SO<sub>4</sub> to water to facilitate its electrolysis in a lecture demonstration. (a) What is the purpose of the Na<sub>2</sub>SO<sub>4</sub>? (b) Why is the water electrolyzed instead of the salt?

**21.108** Subterranean brines in parts of the United States are rich in iodides and bromides and serve as an industrial source of these elements. In one recovery method, the brines are evaporated to dryness and then melted and electrolyzed. Which halogen is more likely to form from this treatment? Why?

**21.109** Zinc plating (galvanizing) is an important means of corrosion protection. Although the process is done customarily by dipping the object into molten zinc, the metal can also be electroplated from aqueous solutions. How many grams of zinc can be deposited on a steel tank from a ZnSO<sub>4</sub> solution when a 0.855-A current flows for 2.50 days?

### Comprehensive Problems

**21.110** The MnO<sub>2</sub> used in alkaline batteries can be produced by an electrochemical process of which one half-reaction is

If a current of 25.0 A is used, how many hours are needed to produce 1.00 kg of MnO<sub>2</sub>? At which electrode is the MnO<sub>2</sub> formed?

**21.111** Car manufacturers are developing engines that use H<sub>2</sub> as fuel. In Iceland, Sweden, and other parts of Scandinavia, where hydroelectric plants produce inexpensive electric power, the H<sub>2</sub> can be made industrially by the electrolysis of water.

(a) How many coulombs are needed to produce 3.5 × 10<sup>6</sup> L of H<sub>2</sub> gas at 12.0 atm and 25°C? (Assume that the ideal gas law applies.)

(b) If the coulombs are supplied at 1.44 V, how many joules are produced?

(c) If the combustion of oil yields 4.0 × 10<sup>4</sup> kJ/kg, what mass of oil must be burned to yield the number of joules in part (b)?

**21.112** The overall cell reaction occurring in an alkaline battery is

(a) How many moles of electrons flow per mole of reaction?

(b) If 4.50 g of zinc is oxidized, how many grams of manganese dioxide and of water are consumed?

(c) What is the total mass of reactants consumed in part (b)?

(d) How many coulombs are produced in part (b)?

(e) In practice, voltaic cells of a given capacity (coulombs) are heavier than the calculation in part (c) indicates. Explain.

**21.113** An inexpensive and accurate method of measuring the quantity of electricity flowing through a circuit is to pass the current through a solution of a metal ion and weigh the metal deposited. A silver electrode immersed in an Ag<sup>+</sup> solution weighs 1.7854 g before the current has passed and weighs 1.8016 g after the current has passed. How many coulombs have passed?

**21.114** Brass, an alloy of copper and zinc, can be produced by simultaneously electroplating the two metals from a solution containing their 2+ ions. If 65.0% of the total current is used to plate copper, while 35.0% goes to plating zinc, what is the mass percent of copper in the brass?

**21.115** A thin circular-disk earring 4.00 cm in diameter is plated with a coating of gold 0.25 mm thick from an Au<sup>3+</sup> bath.

(a) How many days does it take to deposit the gold on one side of one earring if the current is 0.013 A (*d* of gold = 19.3 g/cm<sup>3</sup>)?

(b) How many days does it take to deposit the gold on both sides of the pair of earrings?

(c) If the price of gold is \$1595 per troy ounce (31.10 g), what is the total cost of the gold plating?

**21.116** (a) How many minutes does it take to form 10.0 L of O<sub>2</sub> measured at 99.8 kPa and 28°C from water if a current of 1.3 A passes through the electrolytic cell?

(b) What mass of H<sub>2</sub> forms?

**21.117** Trains powered by electricity, including subways, use direct current. One conductor is the overhead wire (or “third rail” for subways), and the other is the rails upon which the wheels run. The rails are on supports in contact with the ground. To minimize corrosion, should the overhead wire or the rails be connected to the positive terminal? Explain.

**21.118** A silver button battery used in a watch contains 0.75 g of zinc and can run until 80% of the zinc is consumed.

(a) For how many days can the battery produce a current of 0.85 microamp (10<sup>-6</sup> amp)?

(b) When the battery dies, 95% of the Ag<sub>2</sub>O has been consumed. How many grams of Ag were used to make the battery?

(c) If Ag costs \$23.00 per troy ounce (31.10 g), what is the cost of the Ag consumed each day the watch runs?

**21.119** Like any piece of apparatus, an electrolytic cell operates at less than 100% efficiency. A cell depositing Cu from a Cu<sup>2+</sup> bath

operates for 10 h with an average current of 5.8 A. If 53.4 g of copper is deposited, at what efficiency is the cell operating?

**21.120** Commercial electrolysis is performed on both molten NaCl and aqueous NaCl solutions. Identify the anode product, cathode product, species reduced, and species oxidized for the electrolysis of (a) molten NaCl and (b) an aqueous solution of NaCl.

**21.121** To examine the effect of ion removal on cell voltage, a chemist constructs two voltaic cells, each with a standard hydrogen electrode in one compartment. One cell also contains a Pb/Pb<sup>2+</sup> half-cell; the other contains a Cu/Cu<sup>2+</sup> half-cell.

- What is  $E^\circ$  of each cell at 298 K?
- Which electrode in each cell is negative?
- When Na<sub>2</sub>S solution is added to the Pb<sup>2+</sup> electrolyte, solid PbS forms. What happens to the cell voltage?
- When sufficient Na<sub>2</sub>S is added to the Cu<sup>2+</sup> electrolyte, CuS forms and [Cu<sup>2+</sup>] drops to  $1 \times 10^{-16}$  M. Find the cell voltage.

**21.122** Electrodes used in electrocardiography are disposable, and many of them incorporate silver. The metal is deposited in a thin layer on a small plastic “button,” and then some is converted to AgCl:

- If the surface area of the button is 2.0 cm<sup>2</sup> and the thickness of the silver layer is  $7.5 \times 10^{-6}$  m, calculate the volume (in cm<sup>3</sup>) of Ag used in one electrode.
- The density of silver metal is 10.5 g/cm<sup>3</sup>. How many grams of silver are used per electrode?
- If Ag is plated on the button from an Ag<sup>+</sup> solution with a current of 12.0 mA, how many minutes does the plating take?
- If bulk silver costs \$28.93 per troy ounce (31.10 g), what is the cost (in cents) of the silver in one disposable electrode?

**21.123** Commercial aluminum production is done by electrolysis of a bath containing Al<sub>2</sub>O<sub>3</sub> dissolved in molten Na<sub>3</sub>AlF<sub>6</sub>. Why isn't it done by electrolysis of an aqueous AlCl<sub>3</sub> solution?

**21.124** Comparing the standard electrode potentials ( $E^\circ$ ) of the Group 1A(1) metals Li, Na, and K with the negative of their first ionization energies reveals a discrepancy:

Metal	-IE (kJ/mol)	$E^\circ$ (V)
Li	-520	-3.05
Na	-496	-2.71
K	-419	-2.93

Note that the electrode potentials do not decrease smoothly down the group, while the ionization energies do. You might expect that if it is more difficult to remove an electron from an atom to form a gaseous ion (larger IE), then it would be less difficult to add an electron to an aqueous ion to form an atom (smaller  $E^\circ$ ), yet Li<sup>+</sup>(aq) is *more* difficult to reduce than Na<sup>+</sup>(aq). Applying Hess's law, use an approach similar to a Born-Haber cycle to break down the process occurring at the electrode into three steps and label the energy involved in each step. How can you account for the discrepancy?

**21.125** In Appendix D, standard electrode potentials range from about +3 V to -3 V. Thus, it might seem possible to use a half-cell from each end of this range to construct a cell with a voltage of approximately 6 V. However, most commercial aqueous voltaic

cells have  $E^\circ$  values of 1.5–2 V. Why are there no aqueous cells with significantly higher potentials?

**21.126** Tin is used to coat “tin” cans used for food storage. If the tin is scratched, exposing the iron of the can, will the iron corrode more or less rapidly than if the tin were not present? Inside the can, the tin itself is coated with a clear varnish. Explain.

**21.127** Commercial electrolytic cells for producing aluminum operate at 5.0 V and 100,000 A.

- How long does it take to produce exactly 1 metric ton (1000 kg) of aluminum?
- How much electrical power (in kilowatt-hours, kW·h) is used (1 W = 1 J/s; 1 kW·h =  $3.6 \times 10^3$  kJ)?
- If electricity costs \$0.123 per kW·h and cell efficiency is 90.%, what is the cost of electricity to produce exactly 1 lb of aluminum?

**21.128** Magnesium bars are connected electrically to underground iron pipes to serve as sacrificial anodes.

- Do electrons flow from the bar to the pipe or the reverse?
- A 12-kg Mg bar is attached to an iron pipe, and it takes 8.5 yr for the Mg to be consumed. What is the average current flowing between the Mg and the Fe during this period?

**21.129** Bubbles of H<sub>2</sub> form when metal D is placed in hot H<sub>2</sub>O. No reaction occurs when D is placed in a solution of a salt of metal E, but D is discolored and coated immediately when placed in a solution of a salt of metal F. What happens if E is placed in a solution of a salt of metal F? Rank metals D, E, and F in order of *increasing* reducing strength.

**21.130** In addition to reacting with gold (see Problem 21.21), aqua regia is used to bring other precious metals into solution. Balance the skeleton equation for the reaction with Pt:

**21.131** The following reactions are used in batteries:

Reaction I is used in fuel cells, II in the automobile lead-acid battery, and III in an experimental high-temperature battery for powering electric vehicles. The aim is to obtain as much work as possible from a cell, while keeping its weight to a minimum.

- In each cell, find the moles of electrons transferred and  $\Delta G$ .
- Calculate the ratio, in kJ/g, of  $w_{\text{max}}$  to mass of reactants for each of the cells. Which has the highest ratio, which the lowest, and why? (*Note:* For simplicity, ignore the masses of cell components that do not appear in the cell as reactants, including electrode materials, electrolytes, separators, cell casing, wiring, etc.)

**21.132** A current is applied to two electrolytic cells in series. In the first, silver is deposited; in the second, a zinc electrode is consumed. How much Ag is plated out if 1.2 g of Zn dissolves?

**21.133** You are investigating a particular chemical reaction. State all the types of data available in standard tables that enable you to calculate the equilibrium constant for the reaction at 298 K.

**21.134** In an electric power plant, personnel monitor the O<sub>2</sub> content of boiler feed water to prevent corrosion of the boiler tubes. Why does Fe corrode faster in steam and hot water than in cold water?

**21.135** A voltaic cell using Cu/Cu<sup>2+</sup> and Sn/Sn<sup>2+</sup> half-cells is set up at standard conditions, and each compartment has a volume of 345 mL. The cell delivers 0.17 A for 48.0 h.

- (a) How many grams of Cu(s) are deposited?  
 (b) What is the  $[\text{Cu}^{2+}]$  remaining?

**21.136** If the  $E_{\text{cell}}$  of the following cell is 0.915 V, what is the pH in the anode compartment?

**21.137** From the skeleton equations below, create a list of balanced half-reactions in which the strongest oxidizing agent is on top and the weakest is on the bottom:

**21.138** You are given the following three half-reactions:

- (a) Calculate  $\Delta G^\circ$  for (1) and (2) from their  $E^\circ_{\text{half-cell}}$  values.  
 (b) Calculate  $\Delta G^\circ$  for (3) from (1) and (2).  
 (c) Calculate  $E^\circ_{\text{half-cell}}$  for (3) from its  $\Delta G^\circ$ .

**21.139** Use the half-reaction method to balance the equation for the conversion of ethanol to acetic acid in acid solution:

**21.140** When zinc is refined by electrolysis, the desired half-reaction at the cathode is

A competing reaction, which lowers the yield, is the formation of hydrogen gas:

If 91.50% of the current flowing results in zinc being deposited, while 8.50% produces hydrogen gas, how many liters of  $\text{H}_2$ , measured at STP, form per kilogram of zinc?

**21.141** A chemist designs an ion-specific probe for measuring  $[\text{Ag}^+]$  in a NaCl solution saturated with AgCl. One half-cell has an Ag wire electrode immersed in the unknown AgCl-saturated NaCl solution. It is connected through a salt bridge to the other half-cell, which has a calomel reference electrode [a platinum wire immersed in a paste of mercury and calomel ( $\text{Hg}_2\text{Cl}_2$ )] in a saturated KCl solution. The measured  $E_{\text{cell}}$  is 0.060 V.

- (a) Given the following standard half-reactions, calculate  $[\text{Ag}^+]$ .  
 Calomel:  $\text{Hg}_2\text{Cl}_2(s) + 2e^- \longrightarrow 2\text{Hg}(l) + 2\text{Cl}^-(aq) \quad E^\circ = 0.24 \text{ V}$   
 Silver:  $\text{Ag}^+(aq) + e^- \longrightarrow \text{Ag}(s) \quad E^\circ = 0.80 \text{ V}$   
 (*Hint:* Assume that  $[\text{Cl}^-]$  is so high that it is essentially constant.)  
 (b) A mining engineer wants an ore sample analyzed with the  $\text{Ag}^+$ -selective probe. After pretreating the ore sample, the chemist measures the cell voltage as 0.53 V. What is  $[\text{Ag}^+]$ ?

**21.142** Use Appendix D to calculate the  $K_{\text{sp}}$  of AgCl.

**21.143** Black-and-white photographic film is coated with silver halides. Because silver is expensive, the manufacturer monitors the  $\text{Ag}^+$  content of the waste stream,  $[\text{Ag}^+]_{\text{waste}}$ , from the plant with an  $\text{Ag}^+$ -selective electrode at 25°C. A stream of known  $\text{Ag}^+$  concentration,  $[\text{Ag}^+]_{\text{standard}}$ , is passed over the electrode in turn with the waste stream and the data recorded by a computer.

- (a) Write the equations relating the nonstandard cell potential to the standard cell potential and  $[\text{Ag}^+]$  for each solution.

- (b) Combine these into a single equation to find  $[\text{Ag}^+]_{\text{waste}}$ .  
 (c) Rewrite the equation from part (b) to find  $[\text{Ag}^+]_{\text{waste}}$  in ng/L.  
 (d) If  $E_{\text{waste}}$  is 0.003 V higher than  $E_{\text{standard}}$ , and the standard solution contains 1000. ng/L, what is  $[\text{Ag}^+]_{\text{waste}}$ ?  
 (e) Rewrite the equation from part (b) to find  $[\text{Ag}^+]_{\text{waste}}$  for a system in which  $T$  changes and  $T_{\text{waste}}$  and  $T_{\text{standard}}$  may be different.

**21.144** Calculate the  $K_f$  of  $\text{Ag}(\text{NH}_3)_2^+$  from

**21.145** Even though the toxicity of cadmium has become a concern, nickel-cadmium (nicad) batteries are still used commonly in many devices. The overall cell reaction is

A certain nicad battery weighs 18.3 g and has a capacity of 300. mA·h (that is, the cell can store charge equivalent to a current of 300. mA flowing for 1 h).

- (a) What is the capacity of this cell in coulombs?  
 (b) What mass of reactants is needed to deliver 300. mA·h?  
 (c) What percentage of the cell mass consists of reactants?

**21.146** The zinc-air battery is a less expensive alternative to silver batteries for use in hearing aids. The cell reaction is

A new battery weighs 0.275 g. The zinc accounts for exactly  $\frac{1}{10}$  of the mass, and the oxygen does not contribute to the mass because it is supplied by the air.

- (a) How much electricity (in C) can the battery deliver?  
 (b) How much free energy (in J) is released if  $E_{\text{cell}}$  is 1.3 V?

**21.147** Use Appendix D to create an activity series of Mn, Fe, Ag, Sn, Cr, Cu, Ba, Al, Na, Hg, Ni, Li, Au, Zn, and Pb. Rank these metals in order of decreasing reducing strength, and divide them into three groups: those that displace  $\text{H}_2$  from water, those that displace  $\text{H}_2$  from acid, and those that cannot displace  $\text{H}_2$ .

**21.148** Both Ti and V are reactive enough to displace  $\text{H}_2$  from water; of the two metals, Ti is the stronger reducing agent. The difference in their  $E^\circ_{\text{half-cell}}$  values is 0.43 V. Given

use Appendix D to calculate the  $E^\circ_{\text{half-cell}}$  values for  $\text{V}^{2+}/\text{V}$  and  $\text{Ti}^{2+}/\text{Ti}$  half-cells.

**21.149** For the reaction

- (a) Identify the oxidizing and reducing agents. (b) Calculate  $E^\circ_{\text{cell}}$ .  
 (c) For the reduction half-reaction, write a balanced equation, give the oxidation number of each element, and calculate  $E^\circ_{\text{half-cell}}$ .

**21.150** Two concentration cells are prepared, both with 90.0 mL of 0.0100 M  $\text{Cu}(\text{NO}_3)_2$  and a Cu bar in each half-cell.

- (a) In the first concentration cell, 10.0 mL of 0.500 M  $\text{NH}_3$  is added to one half-cell; the complex ion  $\text{Cu}(\text{NH}_3)_4^{2+}$  forms, and  $E_{\text{cell}}$  is 0.129 V. Calculate  $K_f$  for the formation of the complex ion.  
 (b) Calculate  $E_{\text{cell}}$  when an additional 10.0 mL of 0.500 M  $\text{NH}_3$  is added.  
 (c) In the second concentration cell, 10.0 mL of 0.500 M NaOH is added to one half-cell; the precipitate  $\text{Cu}(\text{OH})_2$  forms ( $K_{\text{sp}} = 2.2 \times 10^{-20}$ ). Calculate  $E^\circ_{\text{cell}}$ .  
 (d) What would the molarity of NaOH have to be for the addition of 10.0 mL to result in an  $E^\circ_{\text{cell}}$  of 0.340 V?

**21.151** Two voltaic cells are to be joined so that one will run the other as an electrolytic cell. In the first cell, one half-cell has Au foil in  $1.00\text{ M Au(NO}_3)_3$ , and the other half-cell has a Cr bar in  $1.00\text{ M Cr(NO}_3)_3$ . In the second cell, one half-cell has a Co bar in  $1.00\text{ M Co(NO}_3)_2$ , and the other half-cell has a Zn bar in  $1.00\text{ M Zn(NO}_3)_2$ .

- Calculate  $E_{\text{cell}}^\circ$  for each cell.
- Calculate the total potential if the two cells are connected as voltaic cells in series.
- When the electrode wires are switched in one of the cells, which cell will run as the voltaic cell and which as the electrolytic cell?
- Which metal ion is being reduced in each cell?
- If  $2.00\text{ g}$  of metal plates out in the voltaic cell, how much metal ion plates out in the electrolytic cell?

**21.152** A voltaic cell has one half-cell with a Cu bar in a  $1.00\text{ M Cu}^{2+}$  salt, and the other half-cell with a Cd bar in the same volume of a  $1.00\text{ M Cd}^{2+}$  salt.

- Find  $E_{\text{cell}}^\circ$ ,  $\Delta G^\circ$ , and  $K$ .

- As the cell operates,  $[\text{Cd}^{2+}]$  increases; find  $E_{\text{cell}}$  and  $\Delta G$  when  $[\text{Cd}^{2+}]$  is  $1.95\text{ M}$ .

- Find  $E_{\text{cell}}$ ,  $\Delta G$ , and  $[\text{Cu}^{2+}]$  at equilibrium.

**21.153** Gasoline is a mixture of hydrocarbons, but the heat released when it burns is close to that of octane,  $\text{C}_8\text{H}_{18}(l)$  ( $\Delta H_f^\circ = -250.1\text{ kJ/mol}$ ). Research is underway to use  $\text{H}_2$  from the electrolysis of water in fuel cells to power cars instead of gasoline.

- Calculate  $\Delta H^\circ$  when  $1.00\text{ gal}$  of gasoline ( $d = 0.7028\text{ g/mL}$ ) burns to produce carbon dioxide gas and water vapor.
- How many liters of  $\text{H}_2$  at  $25^\circ\text{C}$  and  $1.00\text{ atm}$  must burn to produce this quantity of energy?
- How long would it take to produce this amount of  $\text{H}_2$  by electrolysis with a current of  $1.00 \times 10^3\text{ A}$  at  $6.00\text{ V}$ ?
- How much power in kilowatt-hours ( $\text{kW}\cdot\text{h}$ ) is required to generate this amount of  $\text{H}_2$  ( $1\text{ W} = 1\text{ J/s}$ ,  $1\text{ J} = 1\text{ C}\cdot\text{V}$ , and  $1\text{ kW}\cdot\text{h} = 3.6 \times 10^6\text{ J}$ )?
- If the cell is  $88.0\%$  efficient and electricity costs  $\$0.123$  per  $\text{kW}\cdot\text{h}$ , what is the cost of producing the amount of  $\text{H}_2$  equivalent to  $1.00\text{ gal}$  of gasoline?

## Concepts and Skills to Review Before You Study This Chapter

- › trends in atomic properties (Sections 8.3, 8.4, 9.2, and 9.5)
- › catalysts and reaction rate (Section 16.7)
- › Le Châtelier's principle (Section 17.6)
- › acid-base equilibria (Sections 18.3 and 18.4)
- › solubility and complex-ion equilibria (Sections 19.3 and 19.4)
- › temperature and reaction spontaneity (Section 20.3)
- › free energy and equilibrium (Section 20.4)
- › standard electrode potentials (Section 21.3)
- › electrolysis of molten salts and aqueous salt solutions (Section 21.7)

To make that sports car you may have dreamed of owning, manufacturers need chemical elements. Iron, in the form of steel, accounts for about 55% of the weight of a typical car and aluminum about 8%. Zinc is used to galvanize some of the metal parts, lead is used in the battery, and copper is needed for the wiring. To make your dream car (or your old, trusty, college-student car) a reality, we need to extract elements from their source, Earth. Chemical principles aid in answering practical questions about this process: how much of the element is present in nature, in what form does it occur, how do organisms affect its distribution, and how do we isolate it for our own use? We'll apply concepts of kinetics, equilibrium, thermodynamics, and electrochemistry from previous chapters to explain some major chemical processes in nature and industry.

**IN THIS CHAPTER . . .** We examine the distribution of elements on Earth and the natural cycles of three key elements. Then, we apply concepts of kinetics, equilibrium, thermodynamics, and electrochemistry from previous chapters to explain the methods that have been developed to extract, purify, and utilize several important elements.

- › We identify the abundances and sources of elements in the various regions of Earth.
- › We consider how three essential elements—carbon, nitrogen, and phosphorus—cycle through the environment and focus on how humans influence these processes.
- › We focus on the isolation and purification of metals, discussing general redox and metallurgical procedures for extracting an element from its ore.
- › We examine in detail the isolation and uses of seven key elements: sodium, potassium, iron, copper, aluminum, magnesium, and hydrogen.
- › We take a close look at two of the most important processes in chemical manufacturing: the production of sulfuric acid and the isolation of chlorine.

## 22.1 HOW THE ELEMENTS OCCUR IN NATURE

To begin our examination of how we use the elements, let's take inventory of our elemental stock—the distribution and relative amounts of the elements on Earth, especially that thin outer portion of our planet that we can reach.

### Earth's Structure and the Abundance of the Elements

Any attempt to isolate an element must begin with a knowledge of its **abundance**, the amount of the element in a particular region of the natural world. The abundances of the elements result from details of our planet's evolution.

**Formation and Layering of Earth** About 4.5 billion years ago, vast clouds of cold gases and interstellar debris from exploded older stars gradually coalesced into the Sun and planets. At first, Earth was a cold, solid sphere of uniformly distributed elements and simple compounds. In the next billion years or so, heat from radioactive decay and continuous meteor impacts raised the planet's temperature to around  $10^4$  K, sufficient to form an enormous molten mass. Any

Figure 22.1 The layered internal structure of Earth.

remaining gaseous elements, such as the cosmically abundant and very light hydrogen and helium, were lost to space.

As Earth cooled, chemical and physical processes resulted in its **differentiation**, the formation of regions of different composition and density. Differentiation gave Earth an internal structure consisting of three layers (Figure 22.1):

- The dense **core** ( $d = 10\text{--}15 \text{ g/cm}^3$ ) is composed of a molten outer core and a solid Moon-sized inner core. Remarkably, the inner core is nearly as hot as the surface of the Sun and spins within the molten outer core slightly faster than Earth itself does!
- The thick, homogeneous **mantle** lying around the core has an overall density of  $4\text{--}6 \text{ g/cm}^3$ .
- A thin, heterogeneous **crust** lies on top of the mantle. The average density of the crust, on which all the comings and goings of life take place, is  $2.8 \text{ g/cm}^3$ .

Table 22.1 compares the abundance of some key elements in the universe, the whole Earth (actually core plus mantle only, which account for more than 99% of Earth's mass), and Earth's three regions. (Because the deepest terrestrial sampling can penetrate only a few kilometers into the crust, some of these data represent extrapolations from meteor samples and from seismic studies of earthquakes.) Several points stand out:

- Cosmic and whole-Earth abundances are very different, particularly for H and He; these two elements account for the majority of the mass of the universe but are not abundant in elemental form on Earth.
- The elements O, Si, Fe, and Mg are abundant both cosmically and on Earth. Together, they account for more than 90% of Earth's mass.
- The core is particularly rich in the dense Group 8B(8) through 8B(10) metals: Co, Ni, and especially Fe, the most abundant element in the whole Earth.

Table 22.1

Cosmic and Terrestrial Abundances (Mass %) of Selected Elements\*

Element	Universe	Earth	Crust	Mantle	Core

\*A missing abundance value indicates either that reliable data are not available or that the value is less than 0.001% by mass.

- Crustal abundances are very different from whole-Earth abundances. The crust makes up only 0.4% of Earth's mass, but has the largest share of nonmetals, metalloids, and light, active metals: Al, Ca, Na, and K. The mantle contains much smaller proportions of these, and the core has none. Oxygen is the most abundant element in the crust and mantle but is absent from the core.

These differences in Earth's major layers arose from the effects of thermal energy. When Earth was molten, gravity and convection caused more dense materials to sink and less dense materials to rise, yielding several compositional *phases*:

- Most of the Fe sank to form the core, or *iron phase*.
- In the light outer phase, oxygen combined with Si, Al, Mg, and some Fe to form silicates, the material of rocks. This *silicate phase* later separated into the mantle and crust.
- The *sulfide phase*, intermediate in density and insoluble in the other two, consisted mostly of iron sulfide and mixed with parts of the silicate phase above and the iron phase below.
- The thin, primitive atmosphere, probably a mixture of water vapor (which gave rise to the oceans), carbon monoxide, and nitrogen (or ammonia), was produced by *outgassing* (the expulsion of trapped gases).

The distribution of the remaining elements (discussed here using only the new periodic table group numbers) was controlled by their chemical affinity for one of the three phases. In general terms, as Figure 22.2 shows:

- Elements with low or high electronegativity—active metals (those in Groups 1 through 5, Cr, and Mn) and nonmetals (O, lighter members of Groups 13 to 15, and all of Group 17)—tended to congregate in the silicate phase as ionic compounds.
- Metals with intermediate electronegativities (many from Groups 6 to 10) dissolved in the iron phase.
- Lower-melting transition metals and many metals and metalloids in Groups 11 to 16 became concentrated in the sulfide phase.

**The Impact of Life on Crustal Abundances** At present, the crust is the only physically accessible layer of Earth, so only crustal abundances have practical significance. The crust is divided into the **lithosphere** (the solid region of the crust), the **hydrosphere** (the liquid region), and the **atmosphere** (the gaseous region). Over billions of years, weathering and volcanic upsurges have dramatically altered the composition of the crust. The **biosphere**, which consists of the living systems that inhabit and have

inhabited the planet, has been another *major influence on crustal element composition and distribution*.

When the earliest rocks were forming and the ocean basins were filling with water, binary inorganic molecules in the atmosphere were reacting to form first simple, and then more complex, organic molecules. The energy for these (mostly) endothermic changes was supplied by lightning, solar radiation, geologic heating, and meteoric impacts. In an amazingly short period of time, probably no more than 500 million years, the first organisms appeared. It took less than another billion years for these to evolve into simple algae that could derive metabolic energy from photosynthesis, converting  $\text{CO}_2$  and  $\text{H}_2\text{O}$  into organic molecules and releasing  $\text{O}_2$  as a byproduct.

Let's look at some of the essential ways the evolution of organisms affected the chemistry of the crust:

1. *Increase in  $\text{O}_2$ .* Due to photosynthesis, the atmosphere gradually became richer in  $\text{O}_2$  over the 300 million years following the emergence of algae. Thus, *oxidation became the major source of free energy in the crust and biosphere*. As a result of this oxidizing environment, the predominating Fe(II)-containing minerals were oxidized to Fe(III)-containing minerals, such as hematite,  $\text{Fe}_2\text{O}_3$ , shown in Figure 22.3A in ancient banded-iron formations (red beds). The increase in oxygen also led to an explosion of  $\text{O}_2$ -utilizing life forms, a few of which evolved into the organisms of today. Figure 22.3B shows a fossil of one of the multicellular organisms whose appearance coincided with the increase in  $\text{O}_2$ .

2.  *$\text{K}^+$  vs.  $\text{Na}^+$ .* The  $\text{K}^+$  concentration of the oceans is much lower than the  $\text{Na}^+$  concentration. Forming over eons from outgassed water vapor condensing into rain and streaming over the land, the oceans became complex ionic solutions with 30 times as much  $\text{Na}^+$  as  $\text{K}^+$ . One reason for this is that plants require  $\text{K}^+$  for growth, so they absorbed dissolved  $\text{K}^+$  that would otherwise have washed down to the sea.

3. *Buried organic carbon.* Enormous subterranean deposits of organic carbon formed when ancient plants, buried deeply and decomposing under high pressure and temperature in the absence of free  $\text{O}_2$ , gradually turned into coal. Animals buried under similar conditions turned into petroleum. Crustal deposits of this organic carbon provide the fuels that move our cars, heat our homes, and electrify our cities.

4. *Fossilized  $\text{CaCO}_3$ .* Carbon and oxygen, together with calcium, the fifth most abundant element in the crust, occur in vast sedimentary deposits all over the world as limestone, dolomite (*see photo*), marble, and chalk, all of which are the fossilized skeletal remains of countless early marine organisms.

Table 22.2 compares selected elemental abundances in the whole crust, the three crustal regions, and the human body, a representative portion of the biosphere. Note the quantities of the four major elements of life—O, C, H, and N. Oxygen is either the first or second most abundant element in all cases. The biosphere contains large amounts of carbon in its biomolecules and large amounts of hydrogen as water. Nitrogen is abundant in the atmosphere as free  $\text{N}_2$  and in organisms as part of their proteins. Phosphorus and sulfur also occur in high amounts in organisms.

One striking difference among the lithosphere, hydrosphere, and biosphere (human) is in the abundances of the transition metals vanadium through zinc. Their relatively insoluble oxides and sulfides make them much scarcer in water than on land. Yet organisms, which evolved in the seas, developed the ability to concentrate the trace amounts of these elements present in their aqueous environment. In every case, the biological concentration is at least 100 times the concentration in the hydrosphere, with Mn increasing about 1000-fold, and Cu, Zn, and Fe even more. These elements perform essential roles in living systems (see Chemical Connections at the end of Chapter 23).

## Sources of the Elements

Given an element's abundance in a region of the crust, we still need to determine its **occurrence**, or **source**, the form(s) in which the element exists. Practical considerations often determine the commercial source. Oxygen, for example, is abundant in

Table 22.2

V	0.015	0.014	—	—	$3 \times 10^{-6}$

all three crustal regions, but the atmosphere is its primary industrial source because it occurs there as the free element. Nitrogen and the noble gases (except helium) are also obtained from the atmosphere. Several other elements occur uncombined, formed in large deposits by prehistoric biological action, such as sulfur in caprock salt domes and nearly pure carbon in coal. The relatively unreactive elements gold and platinum also occur in an uncombined (or *native*) state.

The overwhelming majority of elements, however, occur in **ores**, natural compounds or mixtures of compounds from which an element can be extracted economically (see photo): *the financial costs of mining, isolating, and purifying must be considered when choosing a process to obtain an element.*

Figure 22.4 on the next page shows the most useful sources of the elements. Note that elements with the same types of ores tend to be grouped together in the periodic table:

- Alkali metal halides are ores for both groups of their component elements, Group 1A(1) and Group 7A(17).
- Group 2A(2) metals occur as carbonates in the marble and limestone of mountain ranges, although magnesium is very abundant in seawater (making that the preferred source, as we discuss later).
- Even though many elements occur as silicates, most of these compounds are very stable thermodynamically. Thus, the cost that would be incurred in processing them prohibits their use—aside from silicon, only lithium and beryllium are obtained from their silicates.
- The ores of most industrially important metals are either oxides, which dominate the left half of the transition series, or sulfides, which dominate the right half of the transition series and a few of the main groups beyond.

The reasons for the prominence of oxide and sulfide ores of metallic elements are complex and include weathering processes, selective precipitation (Section 19.3), and relative solubilities. Certain atomic properties are relevant as well. Metals toward the left side of the periodic table have lower ionization energies and electronegativities,

so they tend to give up electrons or hold them loosely in bonds. The  $O^{2-}$  ion is small enough to approach a metal cation closely, which results in a high lattice energy for the metal oxide. In contrast, metals toward the right side have higher ionization energies and electronegativities. Thus, they tend to form bonds that are more covalent, which suits the larger, more polarizable  $S^{2-}$  ion.

### › Summary of Section 22.1

- › As the young Earth cooled, the elements became differentiated into a dense metallic core, a silicate-rich mantle, and a low-density crust.
- › High abundances of light metals, metalloids, and nonmetals are concentrated in the crust, which has three regions: lithosphere (solid), hydrosphere (liquid), and atmosphere (gaseous).
- › The biosphere (living systems) profoundly affected crustal chemistry by producing free  $O_2$ , and thus an oxidizing environment.
- › Some elements occur in their native state, but most are combined in ores. The ores of most important metallic elements are oxides or sulfides.

## 22.2 THE CYCLING OF ELEMENTS THROUGH THE ENVIRONMENT

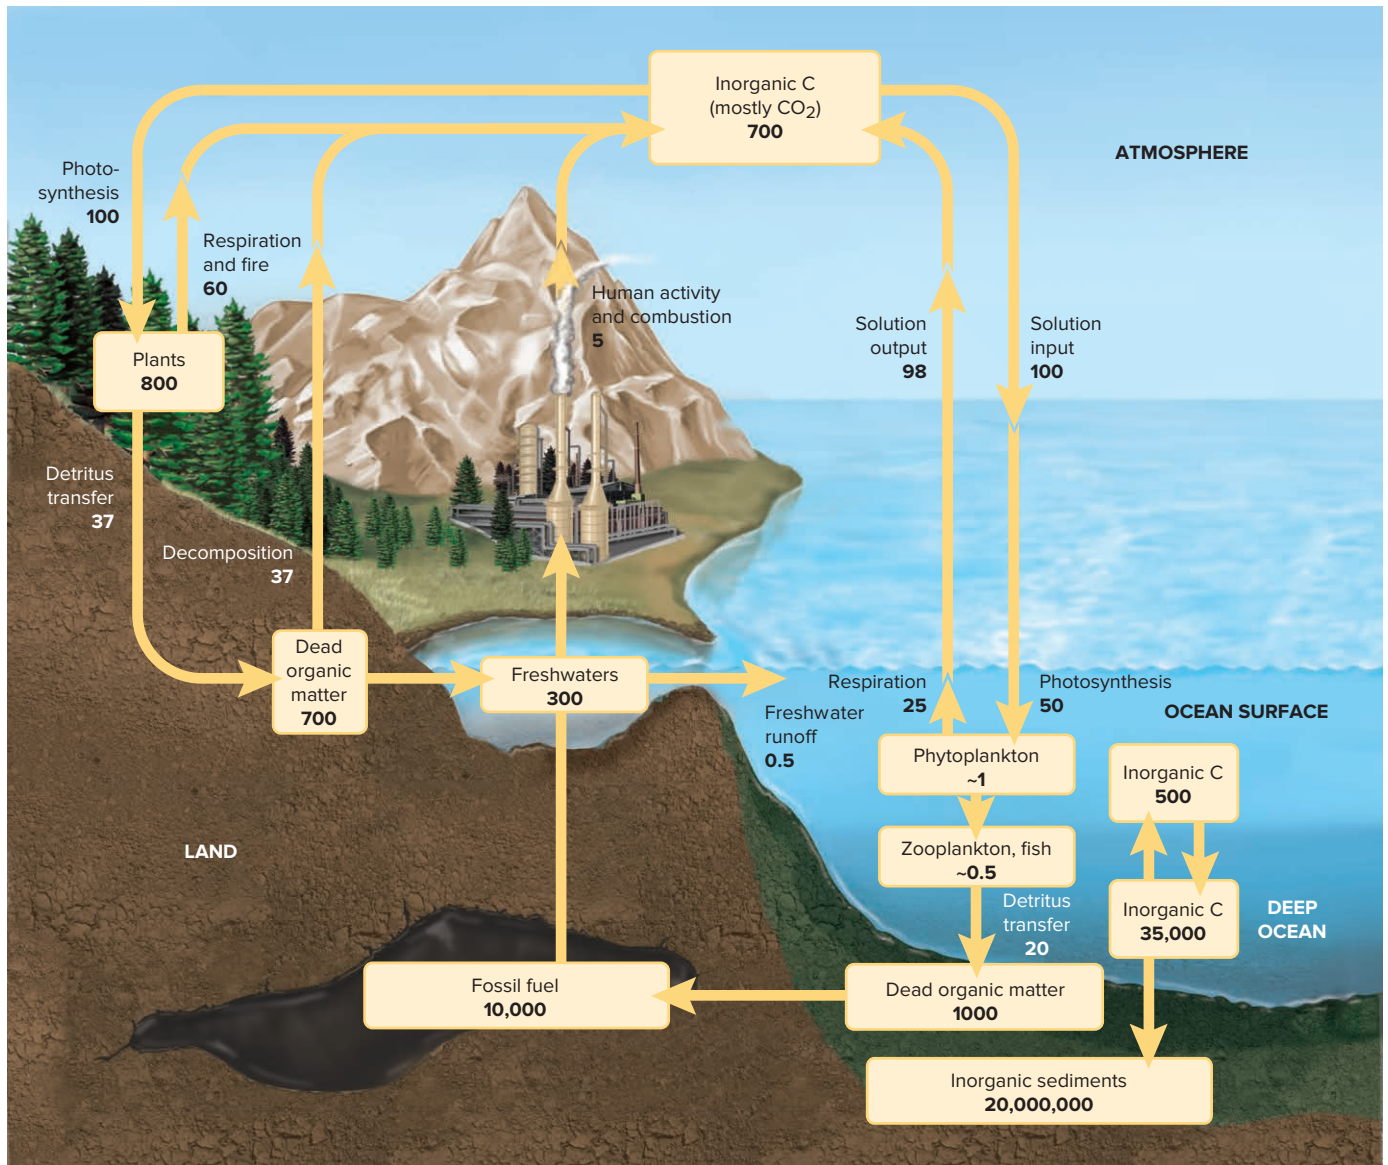

The distributions of many elements change at widely differing rates. The physical, chemical, and biological paths that atoms of an element take through the three regions of the crust—lithosphere, hydrosphere, and atmosphere—constitute the element's **environmental cycle**. In this section, we consider the cycles for carbon, nitrogen, and phosphorus and highlight the effects of humans on them.

### The Carbon Cycle

Carbon is one of a handful of elements that appear in all three regions of Earth's crust.

- In the lithosphere, it occurs in elemental form as graphite and diamond, in fully oxidized form in carbonate minerals, in fully reduced form in petroleum hydrocarbons, and in complex mixtures, such as coal and living matter.
- In the hydrosphere, it occurs in living matter, in carbonate minerals formed by the action of coral-reef organisms, and in dissolved  $CO_2$  and related oxoanions.
- In the atmosphere, it occurs principally in gaseous  $CO_2$ , a minor (0.04%) but essential component that exists in equilibrium with the aqueous fraction.

**Key Interactions Within the Cycle** Figure 22.5 depicts the complex interplay of sources and the effect of the biosphere on carbon's environmental cycle. It provides

**Figure 22.5** The carbon cycle.

Numbers in boxes refer to the size of the source; numbers along arrows refer to the annual movement of the element from source to source. Both sets of values are in  $10^9$  t of C (1 t = 1000 kg = 1.1 tons).

an estimate of the size of each source and, where possible, the amount of carbon moving annually between sources. Note these key points:

- The portions of the cycle are linked by the atmosphere—one link between oceans and air, the other between land and air. The  $2.6 \times 10^{12}$  metric tons of  $\text{CO}_2$  in air cycles through the oceans and atmosphere about once every 300 years but spends a much longer time in carbonate minerals.
- Atmospheric  $\text{CO}_2$  accounts for only 0.04% of crustal carbon but moves the element through the other regions. A  $\text{CO}_2$  molecule spends, on average, 3.5 years in the atmosphere.
- The land and oceans are in contact with the largest sources of carbon, immobilized as carbonates, coal, and oil in rocky sediment beneath the soil.
- *Photosynthesis*, *respiration*, and *decomposition* are major factors in the cycle. **Fixation** is the process of converting a gaseous substance into a condensed form. Via photosynthesis, marine plankton and terrestrial plants use sunlight to fix atmospheric  $\text{CO}_2$  into carbohydrates. Plants release  $\text{CO}_2$  by respiration at night and, much more slowly, when they decompose. Animals eat the plants and release  $\text{CO}_2$  by respiration and decomposition.
- Fires and volcanoes also release  $\text{CO}_2$  into the air.

**Buildup of CO<sub>2</sub> and Global Warming** For hundreds of millions of years, the carbon cycle maintained a relatively constant amount of atmospheric CO<sub>2</sub>, resulting in a relatively constant planetary temperature range. But over the past century and a half, and especially since World War II, atmospheric CO<sub>2</sub> has increased. The principal cause is the combustion of coal, wood, and oil for fuel and the decomposition of limestone to make cement, coupled with the clearing of forests and jungles for lumber, paper, and agriculture. And the principal effect is climate change. The 1990s and 2000s were the hottest decades ever recorded, and 2011–2016 continued this trend. Overwhelming evidence is showing that these activities have led to global warming through the greenhouse effect (see Chemical Connections in Chapter 6). Higher temperatures, alterations in dry and rainy seasons, melting of polar ice, and increasing ocean acidity, with associated changes in carbonate equilibria, are clearly occurring. Nearly all science policy experts are pressing for programs that combine conservation of carbon-based fuels, an end to deforestation, and development of alternative energy sources.

## The Nitrogen Cycle

In contrast to the carbon cycle, the nitrogen cycle includes a *direct* interaction between land and sea (Figure 22.6). All nitrites and nitrates are soluble, so rain and runoff from the land contribute huge amounts of nitrogen to lakes, rivers, and oceans. Human activity, through the use of fertilizer, plays a major role in this cycle.

Like carbon dioxide, atmospheric nitrogen must be fixed. However, whereas CO<sub>2</sub> can be incorporated by plants in either its gaseous or aqueous form, the great stability of N<sub>2</sub> prevents plants from using it directly. Fixation of N<sub>2</sub> requires a great deal of energy and occurs through atmospheric, industrial, and biological processes.

**Figure 22.6** The nitrogen cycle. Numbers in boxes are in 10<sup>9</sup> metric tons of N and refer to the size of the source; numbers along arrows are in 10<sup>6</sup> metric tons of N and refer to the annual movement of the element between sources.

**Atmospheric Fixation** Lightning causes the high-temperature endothermic reaction of  $\text{N}_2$  and  $\text{O}_2$  to form  $\text{NO}$ , which is then oxidized by ozone exothermically to  $\text{NO}_2$ :

During the day,  $\text{NO}_2$  reacts with hydroxyl radical to form  $\text{HNO}_3$ :

At night, a multistep reaction between  $\text{NO}_2$  and ozone is involved. In either case, rain dissociates the nitric acid, and  $\text{NO}_3^-(aq)$  enters both sea and land to be utilized by plants.

**Industrial Fixation** Most human-caused fixation occurs industrially during ammonia synthesis via the Haber process (Section 17.6):

The process takes place on an enormous scale, and  $\text{NH}_3$  ranks first, on a mole basis, among compounds produced industrially. Some of this  $\text{NH}_3$  is converted to  $\text{HNO}_3$  in the Ostwald process (Section 14.7), but most is used as fertilizer, either directly or in the form of urea and ammonium salts (sulfate, phosphate, and nitrate), which enter the biosphere when taken up by plants (as discussed in the next subsection).

In recent decades, high-temperature combustion in electric power plants and in car, truck, and plane engines has become an important contributor to total fixed nitrogen. High engine operating temperatures mimic lightning to form  $\text{NO}$  from the  $\text{N}_2$  and  $\text{O}_2$  in the air taken in to burn the hydrocarbon fuel. The  $\text{NO}$  in exhaust gases reacts to form nitric acid in the atmosphere, which adds to the nitrate load that reaches the ground.

The overuse of fertilizers *and* automobiles presents an increasingly serious water pollution problem in many areas. Leaching of the land by rain causes nitrate from fertilizer use and vehicle operation to enter lakes, rivers, and coastal estuaries and leads to *eutrophication*, the depletion of  $\text{O}_2$  and the death of aquatic animal life from excessive algal and plant growth and decomposition. Excess nitrate also spoils nearby drinkable water.

**Biological Fixation** The biological fixation of atmospheric  $\text{N}_2$  occurs in blue-green algae and in nitrogen-fixing bacteria that live on the roots of leguminous plants (such as peas, alfalfa, and clover). These microbial processes dwarf the previous two, fixing more than seven times as much nitrogen as the atmosphere and six times as much as industry. Root bacteria fix  $\text{N}_2$  by enzymatically reducing it to  $\text{NH}_3$  and  $\text{NH}_4^+$ . Enzymes in other soil bacteria catalyze the multistep oxidation of  $\text{NH}_4^+$  to  $\text{NO}_2^-$  and finally  $\text{NO}_3^-$ , which the plants reduce again to make proteins. When the plants die, still other soil bacteria oxidize the proteins to  $\text{NO}_3^-$ .

Animals eat the plants, break down the plant proteins to make their own proteins, and excrete nitrogenous wastes, such as urea  $[(\text{H}_2\text{N})_2\text{C}=\text{O}]$ . The nitrogen in the proteins is released when the animals die and decompose, and is converted by soil bacteria to  $\text{NO}_2^-$  and  $\text{NO}_3^-$  again. This central pool of inorganic nitrate has three main fates: some enters marine and terrestrial plants, some enters the enormous sediment store of mineral nitrates, and some is reduced by denitrifying bacteria to  $\text{NO}_2^-$  and then reduced further to  $\text{N}_2\text{O}$  and  $\text{N}_2$ , which re-enter the atmosphere to complete the cycle.

## The Phosphorus Cycle

Virtually all the mineral sources of phosphorus contain the phosphate group,  $\text{PO}_4^{3-}$ . The most commercially important ores are **apatites**, compounds of general formula  $\text{Ca}_5(\text{PO}_4)_3\text{X}$ , where X is usually F, Cl, or OH. The cycling of phosphorus through the environment involves three interlocking subcycles (Figure 22.7, *next page*). Two rapid biological cycles—a land-based cycle (*yellow arrows in figure*) completed in a matter of years and a water-based cycle (*blue arrows*) completed in weeks to years—are superimposed on an inorganic cycle (*pink arrows*) that takes millions of years to complete. Unlike the carbon and nitrogen cycles, the phosphorus cycle has no gaseous component and thus does *not* involve the atmosphere.

Figure 22.7 The phosphorus cycle.

**The Inorganic Cycle** Although most phosphorus occurs in phosphate rock formed when Earth's lithosphere solidified, a sizeable amount has come from outer space in meteorites. About 100 metric tons of meteorites enter Earth's atmosphere every day, and with an average P content of 0.1% by mass, they have contributed about  $10^{11}$  metric tons of phosphorus to the crust over Earth's lifetime. The most important components of phosphate rock are nearly insoluble phosphate salts:

$$K_{\text{sp}} \text{ of } \text{Ca}_3(\text{PO}_4)_2 \approx 10^{-29}$$

$$K_{\text{sp}} \text{ of } \text{Ca}_5(\text{PO}_4)_3\text{OH} \approx 10^{-51}$$

$$K_{\text{sp}} \text{ of } \text{Ca}_5(\text{PO}_4)_3\text{F} \approx 10^{-60}$$

Weathering slowly leaches phosphates from the soil and carries the ions through rivers to the sea. Plants in the land-based biological cycle speed up this process. In the ocean, some phosphate is absorbed by organisms in the water-based biological cycle, but the majority is precipitated again by  $\text{Ca}^{2+}$  ion and deposited on the continental shelf. Geologic activity lifts the continental shelves, returning the phosphate to the land.

**The Land-Based Biological Cycle** The biological cycles involve the incorporation of phosphate into organisms (biomolecules, bones, teeth, and so forth) and the release of phosphate through their excretion and decomposition. In the land-based cycle, plants continually remove phosphate from the inorganic cycle. Recall that there are three phosphate oxoanions, which exist in equilibrium in aqueous solution:

In topsoil, phosphates occur as insoluble compounds of  $\text{Ca}^{2+}$ ,  $\text{Fe}^{3+}$ , and  $\text{Al}^{3+}$ . Because they can absorb only the water-soluble dihydrogen phosphate, plants have evolved the ability to secrete acids near their roots to convert the insoluble salts gradually into the soluble ion:

Animals that eat the plants excrete soluble phosphate, which is used by newly growing plants. As plants and animals excrete, die, and decompose, some phosphate

is washed into rivers and the oceans. Most of the 2 million metric tons of phosphate that washes from land to sea each year comes from this biological source. Thus, the biosphere greatly increases the movement of phosphate from lithosphere to hydrosphere.

**The Water-Based Biological Cycle** Various phosphate oxoanions continually enter the aquatic environment. Studies that incorporate trace amounts of radioactive phosphorus into  $\text{H}_2\text{PO}_4^-$  and monitor its uptake show that, within 1 minute, 50% of the ion is taken up by photosynthetic algae, which use it to synthesize their biomolecules (denoted by the top curved arrow in the equation, which shows the overall process):

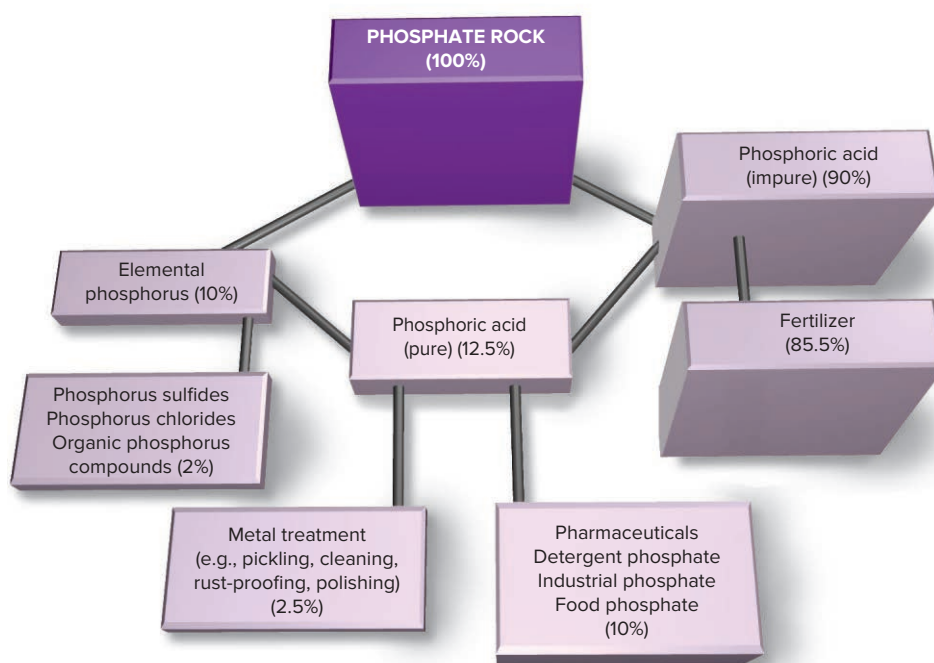

(The complex formula on the right represents the total composition of algal biomolecules, not some particular compound.)

As on land, animals eat the plants and are eaten by other animals, and they all excrete phosphate, die, and decompose (denoted by the bottom curved arrow in the preceding equation). Some of the released phosphate is used by other aquatic organisms, and some returns to the land when fish-eating animals (mostly humans and birds) excrete phosphate, die, and decompose. In addition, some aquatic phosphate precipitates with  $\text{Ca}^{2+}$ , sinks to the seabed, and returns to the long-term mineral deposits of the inorganic cycle.

**Human Effects on Phosphorus Movement** From prehistoric through preindustrial times, these interlocking phosphorus cycles were balanced. Modern human activity, however, alters the movement of phosphorus considerably. Annually, we use more than 100 million tons of phosphate rock. Figure 22.8 shows the major end products, with box height proportional to the mass % of phosphate rock used annually. Removal of phosphate rock has minimal influence on the inorganic cycle, but the end products have unbalanced the two biological cycles.

The imbalance arises from our overuse of *soluble phosphate fertilizers*, such as  $\text{Ca}(\text{H}_2\text{PO}_4)_2$  and  $\text{NH}_4\text{H}_2\text{PO}_4$ , the end products from about 85% of the phosphate rock

**Figure 22.8** Industrial uses of phosphorus.

mined. Some fertilizer finds its way into rivers, lakes, and oceans to enter the water-based cycle. Much larger pollution sources, however, are the crops grown with the fertilizer and the detergents made from phosphate rock. The great majority of this phosphate arrives eventually in cities as crops, as animals that were fed crops, and as consumer products, such as the tripolyphosphates in detergents. Human garbage, excrement, wash water with detergents, and industrial wastewater containing phosphate are carried through sewers to the aquatic system. This human contribution equals the natural contribution—another 2 million metric tons of phosphate per year. The increased concentration in rivers and lakes causes eutrophication, which robs the water of  $O_2$  so that it cannot support life. Such “dead” rivers and lakes are no longer usable for fishing, drinking, or recreation.

A century ago, in 1912, Lake Zurich in Switzerland had been choked with algae and become devoid of fish. Treatment with  $FeCl_3$  precipitated enough phosphate to gradually return the lake to its natural state. Soluble aluminum compounds have the same effect:

### › Summary of Section 22.2

- › The environmental distribution of many elements changes cyclically with time and is affected in major ways by organisms.
- › Carbon occurs in all three regions of Earth’s crust, with atmospheric  $CO_2$  linking the other two regions. Photosynthesis and decomposition of organisms alter the amount of carbon in the land and oceans. Human activity has increased atmospheric  $CO_2$ , leading to climate change.
- › Nitrogen is fixed by lightning, by industry, and primarily by microorganisms. When plants or animals decompose, bacteria convert proteins to nitrites and nitrates and eventually to  $N_2$ , which returns to the atmosphere. Through extensive use of fertilizers, humans have added excess nitrogen to freshwaters.
- › The phosphorus cycle has no gaseous component. Inorganic phosphates leach slowly into land and water, where biological cycles interact. When plants and animals decompose, they release phosphate to natural waters, where it is then absorbed by other plants and animals. Through overuse of phosphate fertilizers and detergents, humans double the amount of phosphorus entering the aqueous environment.

## 22.3 METALLURGY: EXTRACTING A METAL FROM ITS ORE

**Metallurgy** is the branch of materials science concerned with the extraction and utilization of metals. In this section, we discuss the general procedures for isolating metals and, occasionally, the nonmetals that are found in their ores. The extraction process applies one or more of these three types of metallurgy:

- *Pyrometallurgy* uses heat to obtain the metal.
- *Electrometallurgy* employs an electrochemical step.
- *Hydrometallurgy* relies on the metal’s aqueous solution chemistry.

The extraction of an element begins with *mining the ore*. Most ores consist of a mineral attached to gangue. The **mineral** contains the element; it is defined as a naturally occurring, homogeneous, crystalline inorganic solid, with a well-defined composition. The **gangue** is the portion of the ore with no commercial value, such as sand, rock, and clay. Table 22.3 lists the common mineral sources of some metals.

Humans have been removing metals from the crust for thousands of years, so most of the concentrated sources are gone, and, in many cases, ores contain very low mass percents of a metal. The general procedure for extracting most metals (and

Table 22.3

some nonmetals) involves a few basic steps, described in the upcoming subsections (Figure 22.9).

## Pretreating the Ore

Following a crushing, grinding, or pulverizing step, which can be very expensive, pretreatment uses some physical or chemical difference to separate mineral from gangue. The following are common pretreatment techniques:

- *Magnetic attraction.* For magnetic minerals, such as magnetite ( $\text{Fe}_3\text{O}_4$ ), a magnet can remove the mineral and leave the gangue behind.
- *Density separation.* When large density differences exist, a *cyclone separator* blows high-pressure air through the pulverized mixture to separate the particles. The lighter silicate-rich gangue is blown away, while the denser mineral-rich particles hit the walls of the separator and fall through the open bottom (Figure 22.10).
- *Flotation.* In **flotation**, an oil-detergent mixture is stirred with the pulverized ore in water to form a slurry (Figure 22.11). The surfaces of mineral and of gangue become wet to different extents with water and detergent. Rapid mixing with air produces an oily, mineral-rich froth that floats, while the silicate particles sink. Skimming, followed by solvent removal, isolates the concentrated mineral fraction.
- *Leaching.* Some metals are extracted by a hydrometallurgical process known as **leaching**, usually accomplished via formation of a complex ion. The modern extraction of gold is a good example of this technique. The crushed ore, which often contains as little as 25 ppm of gold, is contained in a plastic-lined pool, treated with a cyanide ion solution, and aerated. In the presence of  $\text{CN}^-$ , the  $\text{O}_2$  in air oxidizes gold metal to gold(I) ion,  $\text{Au}^+$ , which forms the soluble complex ion,  $\text{Au}(\text{CN})_2^-$ :

(This method is controversial because cyanide enters streams and lakes, where it poisons fish and birds.)

Figure 22.10 The cyclone separator.

Figure 22.11 The flotation process.

## Converting Mineral to Element

After the mineral has been freed of debris and concentrated, it may undergo several chemical steps during its conversion to the element.

**Converting the Mineral to Another Compound** First, the mineral is often converted to another compound, one that has different solubility properties, is easier to reduce, or is free of an impurity. Conversion to an oxide is common because oxides can be reduced easily. Carbonates are heated to convert them to the oxide:

Metal sulfides, such as ZnS, can be converted to oxides by **roasting** in air:

In most countries, hydrometallurgical methods are now used to avoid the atmospheric release of SO<sub>2</sub> from roasting. One way of processing copper, for example, is by bubbling air through an acidic slurry of insoluble Cu<sub>2</sub>S, which completes both the pretreatment and conversion steps:

**Converting Compound to Element Through Chemical Redox** The next step converts the new mineral form (usually an oxide) to the free element by either chemical or electrochemical redox methods. Let's consider the chemical methods first. In these processes, a reducing agent reacts directly with the compound. The most common reducing agents are carbon, hydrogen, and a more active metal.

1. *Reduction with carbon.* Because of its low cost and ready availability, carbon, in the form of coke (a porous material obtained from incomplete combustion of coal) or charcoal, is a common reducing agent. Heating an oxide with a reducing agent such as coke to obtain the metal is called **smelting**. Many metal oxides, such as zinc oxide and tin(IV) oxide, are smelted with carbon to free the metal, which then may need to be condensed and solidified (note the physical states of the metal products):

Several nonmetals that occur with positive oxidation states in minerals can be reduced with carbon as well. Phosphorus, for example, is produced from calcium phosphate:

(Metallic calcium is a much stronger reducing agent than carbon, so it is not formed.)

- *Thermodynamic considerations.* Thermodynamic principles explain why carbon is often such an effective reducing agent. Consider the standard free energy change ( $\Delta G^\circ$ ) for the reduction of tin(IV) oxide:

The magnitude and sign of  $\Delta G^\circ$  indicate a highly *nonspontaneous* reaction at standard-state conditions and 298 K. However, because solid C becomes gaseous CO, the standard molar entropy change is very positive ( $\Delta S^\circ \approx 380 \text{ J/K}$ ). Therefore, *the  $-T\Delta S^\circ$  term of  $\Delta G^\circ$  becomes more negative with higher temperature* (Section 20.3). As the temperature increases,  $\Delta G^\circ$  decreases, and at a high enough temperature, the reaction becomes spontaneous ( $\Delta G^\circ < 0$ ). At 1000°C (1273 K), for example,  $\Delta G^\circ = -62.8 \text{ kJ}$ . The actual process is carried out at a temperature of around 1250°C (1523 K), so  $\Delta G^\circ$  is even more negative. In effect, the nonspontaneous reduction of SnO<sub>2</sub> is coupled to the spontaneous oxidation of C.

- *Multistep nature of the process.* As you know, overall reactions often actually occur through several intermediate steps. For instance, the reduction of tin(IV) oxide involves formation of tin(II) oxide:

[Molten tin (mp = 232 K) is obtained at this temperature.] The second step is thought to be composed of others, in which CO, not C, is the actual reducing agent:

Other pyrometallurgical processes are similarly complex. For instance, shortly you'll see that the overall reaction for the smelting of iron is

However, the actual process is a multistep one with CO as the reducing agent. The advantage of CO over C is the far greater physical contact the gaseous reducing agent can make with the other reactant, which speeds the process.

2. *Reduction with hydrogen.* For oxides of some metals, especially some members of Groups 6B(6) and 7B(7), reduction with carbon forms metal carbides that are difficult to convert further, so hydrogen is used as the reducing agent instead, especially for less active metals, such as tungsten:

One step in the purification of the metalloid germanium also uses hydrogen:

3. *Reduction with a more active metal.* If a metal oxide forms both an undesirable carbide and an undesirable hydride, it is reduced by a more active metal. In the *thermite reaction*, aluminum powder reduces the metal oxide in a spectacular exothermic reaction to give the molten metal (Figure 22.12). The reaction for chromium is

Reduction by an active metal is also used when the mineral of the element is not an oxide. In the extraction of gold, after the pretreatment by leaching, the gold(I) complex ion is reduced with zinc:

In some cases, an active metal, such as calcium, is used to recover an even more active metal, such as rubidium, from its molten salt:

A similar process (detailed in Section 22.4) is used to recover sodium.

4. *Oxidation to obtain a nonmetal.* Just as *reduction* of a mineral is used to obtain the metal, *oxidation* of a mineral can be used to obtain a nonmetal. A stronger oxidizing agent removes electrons from the nonmetal anion to give the free nonmetal, as in the production of iodine from concentrated brines:

**Converting Compound to Element Through Electrochemical Redox** In electrochemical redox processes, the minerals are converted to the elements in an electrolytic cell (Section 21.7). Sometimes, the *pure* mineral, in the form of the molten halide or oxide, is used to prevent unwanted side reactions. The cation is reduced to the metal at the cathode, and the anion is oxidized to the nonmetal at the anode:

High-purity hydrogen gas is prepared by electrochemical reduction:

Specially designed cells separate the products to prevent recombination. An inexpensive source of electricity is used for large-scale methods. The current and voltage requirements depend on the electrochemical potential and any necessary overvoltage (Section 21.7).

Figure 22.13 on the next page shows the most common redox step used in obtaining each free element from its mineral.

- Reduction of oxide with C (coke or charcoal)
- Oxidation of anion (or oxoanion) chemically and/or electrolytically

## Refining and Alloying the Element

After being isolated, the element typically still contains impurities, so it must be refined to purify it further. Then, metallic elements are often alloyed to improve their properties.

**Refining (Purifying) the Element** Refining is often carried out by one of three common methods:

1. *Electrorefining.* An electrolytic cell is employed in **electrorefining**, in which the *impure metal acts as the anode and the pure metal as the cathode*. As the reaction proceeds, the anode disintegrates, and the metal ions are reduced to deposit on the cathode. In some cases (as with copper, discussed shortly), impurities that fall beneath the anode are the source of several valuable and less abundant elements.
2. *Distillation.* Metals with relatively low boiling points, such as zinc and mercury, are refined by *distillation*.
3. *Zone refining.* In the process of **zone refining**, a rod of an impure metal or metalloid (such as silicon) is passed slowly through a heating coil in an inert atmosphere. The first narrow zone of the impure solid melts, and as the next zone melts, the dissolved impurities from the first zone lower the freezing point, so the solvent (purer solid of first zone) refreezes. The process continues, zone by zone, for the entire rod. After several passes through the coil, in which each zone's impurities move into the adjacent zone, the refrozen solid at the end of the rod becomes extremely pure (Figure 22.14). Metalloids used in electronic semiconductors, such as silicon and germanium, are zone refined to greater than 99.999999% purity.

**Figure 22.14** Zone refining of silicon.

**Alloying the Purified Element** An **alloy** is a metal-like mixture consisting of solid phases of two or more pure elements (a solid solution) or, in some cases, distinct intermediate phases (these alloys are sometimes referred to as *intermetallic compounds*) that are so finely divided they can only be distinguished microscopically. Alloying a metal with other metals (and, in some cases, nonmetals) is done to alter the metal's melting point and to enhance properties such as luster, conductivity, malleability, ductility, and strength.

Iron is used only when alloyed. In pure form, it is soft and corrodes easily. However, when alloyed with carbon and other metals, such as Mo for hardness and Cr and Ni for corrosion resistance, it forms various steels. Copper stiffens when zinc is added to it to make brass. Mercury solidifies when alloyed with sodium, and

Table 22.4

Some Important Alloys and Their Composition

Name	Composition (Mass %)	Uses
<b>Mostly Fe</b>		
Stainless steel	73–79 Fe, 14–18 Cr, 7–9 Ni	Cutlery, instruments
Nickel steel	96–98 Fe, 2–4 Ni	Cables, gears
High-speed steels	80–94 Fe, 14–20 W (or 6–12 Mo)	Cutting tools
<b>Mostly Cu</b>		
Bronzes	70–95 Cu, 1–25 Zn, 1–18 Sn	Statues, castings
Brasses	50–80 Cu, 20–50 Zn	Plating, ornamental objects
<b>Mostly precious metals</b>

Typical tin solder	67 Pb, 33 Sn	Electrical connections

vanadium becomes extremely tough with some carbon added. Table 22.4 shows the composition and uses of some common alloys.

The simplest alloys, called *binary alloys*, contain only two elements, which can combine in two ways:

- *The added element enters interstices*, spaces between the parent metal atoms in its crystal structure (Section 12.6). In vanadium carbide, for instance, carbon atoms occupy holes of a face-centered cubic vanadium unit cell (Figure 22.15A).
- *The added element substitutes for atoms of the parent*. In many types of brass, for example, relatively few zinc atoms substitute randomly for copper atoms in the face-centered cubic copper unit cell (see Figure 13.4A). On the other hand,  $\beta$ -brass is an intermediate phase that crystallizes as the Zn/Cu ratio approaches 1/1 in a body-centered cubic structure with a central Zn atom surrounded by eight Cu atoms (Figure 22.15B). In one alloy of copper and gold, Cu atoms occupy the faces of a face-centered cube, and Au atoms lie at the corners (Figure 22.15C).

Atomic properties, including size, electron configuration, and number of valence electrons, determine which metals form stable alloys. For example, transition metals from the left half of the *d* block [Groups 3B(3) to 5B(5)] often form alloys with metals from the right half [Groups 8B(9) to 1B(11)]: electron-poor Zr, Nb, and Ta form strong alloys with electron-rich Ir, Pt, and Au; an example is the very stable  $\text{ZrPt}_3$ .

Figure 22.15 Three binary alloys.

### › Summary of Section 22.3

- › Metallurgy involves mining an ore, separating it from debris, pretreating it to concentrate the mineral source, converting the mineral to another compound that is easier to process further, reducing this compound to the metal, purifying the metal, and in many cases, alloying it to obtain a more useful material.

## 22.4 TAPPING THE CRUST: ISOLATION AND USES OF SELECTED ELEMENTS

The isolation process depends on the physical and chemical properties of the source: we isolate an element that occurs uncombined in the air differently from one dissolved in the sea or one found in a rocky ore. In this section, we detail methods for recovering some important elements.

### Producing the Alkali Metals: Sodium and Potassium

The alkali metals are among the most reactive elements and thus are always found as ions in nature, either in solid minerals or in aqueous solution. The two most important of these metals are sodium and potassium. Their abundant, water-soluble compounds are used throughout industry and research, and the  $\text{Na}^+$  and  $\text{K}^+$  ions are essential to organisms.

**Industrial Production of Sodium and Potassium** Different methods are employed in the industrial production of these two metals:

1. *Production of sodium.* The sodium ore is *halite* (largely  $\text{NaCl}$ ), which is obtained either by evaporation of concentrated salt solutions called *brines* (see photo) or by mining vast salt deposits formed from the evaporation of prehistoric seas. The Cheshire salt field in Britain, for example, is 60 km by 24 km by 400 m thick and contains more than 90%  $\text{NaCl}$ . Other large deposits occur in New Mexico, Michigan, New York, and Kansas.

The brine is evaporated and the solid crushed and fused (melted) for use in an electrolytic apparatus called the **Downs cell** (Figure 22.16). To reduce heating costs, 1 part  $\text{NaCl}$  (mp =  $801^\circ\text{C}$ ) is mixed with  $1\frac{1}{2}$  parts  $\text{CaCl}_2$  to form a mixture that melts at only  $580^\circ\text{C}$ . Reduction of the metal ions to Na and Ca takes place at a cylindrical steel cathode, with the molten metals floating on the denser molten salt mixture. As they rise through a short collecting pipe, the liquid Na is siphoned off, while a higher melting Na/Ca alloy solidifies and falls back into the molten electrolyte. Chloride ions are oxidized to  $\text{Cl}_2$  gas at a large anode within an inverted cone-shaped chamber that separates the metals from the  $\text{Cl}_2$  to prevent their explosive recombination. The  $\text{Cl}_2$  is purified and sold as a valuable byproduct.

2. *Production of potassium.* Sylvite (mostly  $\text{KCl}$ ) is the major ore of potassium. The metal is too soluble in molten  $\text{KCl}$  to be obtained by a method similar to that used for sodium. Instead, chemical reduction of  $\text{K}^+$  ions by Na is based on atomic properties and the nature of equilibrium systems. An Na atom is smaller than a K atom, so it holds its outer electron more tightly:  $\text{IE}_1$  of Na =  $496 \text{ kJ/mol}$ ;  $\text{IE}_1$  of K =  $419 \text{ kJ/mol}$ . Thus, based on this atomic property, Na would not be effective at reducing  $\text{K}^+$  because the equilibrium constant would favor reactants. However, the reduction is carried out at  $850^\circ\text{C}$ , which is above the boiling point of K, so the equilibrium mixture contains *gaseous* K:

As the K gas is removed, Le Châtelier's principle predicts that the reaction shifts to the right and produces more K. The gas is then condensed and purified by fractional distillation. The same general method (with Ca as the reducing agent) is used to produce rubidium and cesium.

Evaporative salt beds near Redwood City, California.

**Figure 22.16** The Downs cell for production of sodium.

**Uses of Sodium and Potassium** The compounds of Na and K (and indeed, of all the alkali metals) have many more uses than the elements themselves. Nevertheless, there are some interesting uses of the metals that take advantage of their strong reducing power:

1. *Uses of sodium.* Large amounts of Na were used as an alloy with lead to make gasoline antiknock additives, such as tetraethyllead:

The toxic effects of environmental lead have limited this use to aviation fuel in the United States. Moreover, although leaded gasoline is still used in several developing countries, the global market for tetraethyllead is declining more than 15% annually.

If certain types of nuclear reactors, called *breeder reactors* (Chapter 24), become a practical way to generate energy in the United States, Na production would increase enormously. Its low melting point, viscosity, and interaction with neutrons, combined with its high thermal conductivity and heat capacity, make it perfect for cooling the reactor and exchanging heat to the steam generator.

2. *Uses of potassium.* The major use of potassium at present is in an alloy with sodium for use as a heat exchanger in chemical and nuclear reactors. Another application relies on production of its superoxide, which it forms by direct contact with  $\text{O}_2$ :

This material is employed as an emergency source of  $\text{O}_2$  in breathing masks for miners, divers, submarine crews, and firefighters (*see photo*):

## The Indispensable Three: Iron, Copper, and Aluminum

Their innumerable applications make iron (in the form of steel), copper, and aluminum indispensable metals in an industrial society.

**Metallurgy of Iron: From Ore to Pig Iron** Although people have practiced iron smelting for more than 3000 years, it was not even 250 years ago that iron assumed

Firefighter with  $\text{KO}_2$  breathing mask.

**Important Minerals  
of Iron**

Table 22.5

Mineral Type	Mineral, Formula
Oxide	Hematite, Fe <sub>2</sub> O <sub>3</sub>
	Magnetite, Fe <sub>3</sub> O <sub>4</sub>
	Ilmenite, FeTiO <sub>3</sub>
Carbonate	Siderite, FeCO <sub>3</sub>
Sulfide	Pyrite, FeS <sub>2</sub>
	Pyrrhotite, FeS

its current dominant role. In 1773, an inexpensive process to convert coal to carbon in the form of coke was discovered, and the coke process made iron smelting cheap and efficient and led to large-scale iron production, which ushered in the Industrial Revolution.

Modern society rests, quite literally, on the various alloys of iron known as **steel**. Although steel production has obviously grown enormously since the 18<sup>th</sup> century, the process of recovering iron from its ores still employs *reduction by carbon in a blast furnace*. The most abundant minerals of iron are listed in Table 22.5. Only the first four are used for steelmaking, because traces of sulfur from the sulfide minerals make steel brittle.

The conversion from ore to metal involves a series of redox and acid-base reactions that appear simple, even though their detailed chemistry is not completely understood even today. A modern **blast furnace** (Figure 22.17) is a tower made of brick, about 14 m wide by 40 m high. The *charge*, which usually consists of hematite, coke, and limestone, is fed through the top. More coke is burned in air at the bottom. The charge falls and meets a *blast* of rapidly rising hot air created by the burning coke:

At the bottom of the furnace, the temperature exceeds 2000°C, while at the top, it reaches only 200°C. Because the blast of hot air passes through the entire furnace in only 10 s, the various gas-solid reactions do *not* reach equilibrium, and many intermediate products form. As a result, different stages of the overall reaction process occur at different heights:

1. In the upper part of the furnace (200°C to 700°C), the charge is preheated, and a *partial reduction* occurs. The hematite (Fe<sub>2</sub>O<sub>3</sub>) is reduced to magnetite (Fe<sub>3</sub>O<sub>4</sub>) and then to iron(II) oxide (FeO) by CO, which is the actual reducing agent. Carbon dioxide is formed as well. Limestone (CaCO<sub>3</sub>) also decomposes to form CO<sub>2</sub> and the basic oxide CaO.
2. Lower down, at 700°C to 1200°C, a *final reduction* step occurs, as some of the coke reduces CO<sub>2</sub> to form more CO, which reduces the FeO to Fe.

**Figure 22.17** The major reactions in a blast furnace.

**Figure 22.18** The basic-oxygen process for making steel.

Source: © Luis Veiga/Getty Images

- At temperatures between 1200°C and 1500°C, the iron melts and drips to the bottom of the furnace. Acidic silica particles from the gangue react with the CaO in a Lewis acid-base reaction to form a molten waste product called **slag**:

The slag drips down and floats on the denser iron.

- Some unwanted reactions occur between 1500°C and 2000°C. Any remaining phosphates and silicates are reduced to P and Si, and some Mn and traces of S dissolve into the molten iron along with carbon. The resulting impure product is called *pig iron* and contains about 3% to 4% C. A small amount of pig iron is used to make *cast iron*, but most is purified and alloyed to make various kinds of steel.

**Metallurgy of Iron: From Pig Iron to Steel** Pig iron is converted to steel in a separate furnace by means of the **basic-oxygen process** (Figure 22.18). High-pressure O<sub>2</sub> is blown over and through the molten iron, so that impurities (C, Si, P, Mn, and S) are oxidized rapidly. The highly negative standard enthalpies of formation of the carbon and silicon oxides ( $\Delta H_f^\circ$  of CO<sub>2</sub> = -394 kJ/mol;  $\Delta H_f^\circ$  of SiO<sub>2</sub> = -911 kJ/mol) raise the temperature, which speeds the reaction. A lime (CaO) flux is added, which converts the oxides to a molten slag [primarily CaSiO<sub>3</sub> and Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>] that is decanted from the molten steel. The product is **carbon steel**, which contains 1% to 1.5% C and other impurities. It is alloyed with metals that prevent corrosion and increase its strength or flexibility.

**Metallurgy of Copper: From Ore to Impure Metal** After many centuries of being mined to make bronze and brass, copper ores have become much less plentiful and less rich in copper. Despite this, more than 2.5 billion pounds of copper is produced in the United States annually. The most common ore is chalcopyrite, CuFeS<sub>2</sub>, a mixed sulfide of FeS and CuS (*see photo*). Most remaining deposits contain less than 0.5% Cu by mass. To “win” this small amount of copper requires several metallurgical steps:

- Flotation.** The low copper content in chalcopyrite must be enriched by removing the iron. The first step is pretreatment by flotation (see Figure 22.11), which concentrates the ore to around 15% Cu by mass.

Mining chalcopyrite.

Source: © Lee Prince/Shutterstock.com

2. *Roasting.* The next step in many processing plants is a controlled roasting step, which oxidizes the FeS but not the CuS:

3. *Heating with sand.* To remove the FeO and convert the CuS to a more convenient form, the mixture is heated to 1100°C with sand and more of the concentrated ore. Several reactions occur in this step. The FeO reacts with sand to form a molten slag:

The CuS is thermodynamically unstable at the elevated temperature and decomposes to yield Cu<sub>2</sub>S, which is drawn off as a liquid.

4. *Smelting.* In the final smelting step, the Cu<sub>2</sub>S is roasted in air, which converts some of it to Cu<sub>2</sub>O:

The two copper(I) compounds then react, with sulfide ion acting as the reducing agent:

The copper obtained at this stage is usable for plumbing, but it must be purified further for electrical wiring applications by removal of the unwanted Fe and Ni as well as the valuable byproducts Ag, Au, and Pt.

**Metallurgy of Copper: Electrorefining** Achieving the desired 99.99% purity needed for wiring (copper's most important use) is accomplished by *electrorefining*, which involves the oxidation of Cu to form Cu<sup>2+</sup> ions in solution, followed by their reduction and the plating out of Cu metal (Figure 22.19). The impure copper obtained from smelting is cast into plates to be used as anodes, and cathodes are made from already purified copper. The electrodes are immersed in acidified CuSO<sub>4</sub> solution, and a voltage is applied that accomplishes two tasks simultaneously:

- Copper and the more active impurities (Fe, Ni) are oxidized to their cations, while the less active ones (Ag, Au, Pt) are not. As the anode slabs react, these unoxidized metals fall off as valuable “anode mud” and are purified separately. Sale of the precious metals in the anode mud nearly offsets the cost of electricity to operate the cell, making Cu wire inexpensive.
- Because Cu is much less active than the Fe and Ni impurities, Cu<sup>2+</sup> ions are reduced at the cathode, but Fe<sup>2+</sup> and Ni<sup>2+</sup> ions remain in solution:

**Figure 22.19** The electrorefining of copper.  
Source: © Tom Hollyman/Science Source

**Metallurgy of Aluminum: From Ore to Metal** Aluminum is the most abundant metal in Earth's crust by mass and the third most abundant element (after O and Si). It is found in numerous aluminosilicate minerals, such as feldspars, micas, and clays, and in the rare gems garnet, beryl, spinel, and turquoise. Corundum, pure aluminum oxide ( $\text{Al}_2\text{O}_3$ ), is extremely hard; mixed with traces of transition metals, it exists as ruby and sapphire. Impure  $\text{Al}_2\text{O}_3$  is used in sandpaper and other abrasives.

Through eons of weathering, certain clays became *bauxite*, the major ore of aluminum. This mixed oxide-hydroxide occurs in enormous surface deposits in Mediterranean and tropical regions (*see photo*), but with world aluminum production near 100 million tons annually, it may someday be scarce. In addition to hydrated  $\text{Al}_2\text{O}_3$  (about 75%), industrial-grade bauxite also contains  $\text{Fe}_2\text{O}_3$ ,  $\text{SiO}_2$ , and  $\text{TiO}_2$ , which are removed during the extraction. The overall two-step process combines hydro- and electrometallurgical techniques:

1. *Isolating  $\text{Al}_2\text{O}_3$  from bauxite.* After mining, bauxite is pretreated by boiling in 30%  $\text{NaOH}$  in the *Bayer process*, which involves acid-base, solubility, and complex-ion equilibria. The acidic  $\text{SiO}_2$  and the amphoteric  $\text{Al}_2\text{O}_3$  dissolve in the base, but the basic  $\text{Fe}_2\text{O}_3$  and  $\text{TiO}_2$  do not:

Further heating precipitates the  $\text{Na}_2\text{Si}(\text{OH})_6$  as an aluminosilicate, which is filtered out with the insoluble  $\text{Fe}_2\text{O}_3$  and  $\text{TiO}_2$  (“red mud”).

Acidifying the filtrate precipitates  $\text{Al}^{3+}$  as  $\text{Al}(\text{OH})_3$ . Recall that the aluminate ion,  $\text{Al}(\text{OH})_4^-$  ( $aq$ ), is actually the complex ion  $\text{Al}(\text{H}_2\text{O})_2(\text{OH})_4^-$  (see Figure 19.19). Weakly acidic  $\text{CO}_2$  is added to produce a small amount of  $\text{H}^+$  ion, which reacts with this complex ion to form  $\text{Al}(\text{H}_2\text{O})_3(\text{OH})_3$ . Cooling supersaturates the solution, and the solid that forms is filtered out:

[Recall that we usually write  $\text{Al}(\text{H}_2\text{O})_3(\text{OH})_3$  more simply as  $\text{Al}(\text{OH})_3$ .]

Drying at high temperature converts the hydroxide to the oxide:

2. *Converting  $\text{Al}_2\text{O}_3$  to the free metal: the Hall-Heroult process.* Aluminum is an active metal, much too strong a reducing agent to be formed at the cathode from aqueous solution (Section 21.7), so the oxide itself is electrolyzed.

The melting point of  $\text{Al}_2\text{O}_3$  is very high ( $2030^\circ\text{C}$ ), so it is dissolved in molten *cryolite* ( $\text{Na}_3\text{AlF}_6$ ) to give a mixture that electrolyzes at  $\sim 1000^\circ\text{C}$ . Using cryolite provides a major energy (and thus, cost) savings, but the only sizeable cryolite mines cannot supply enough of the mineral, so production of synthetic cryolite has become a major subsidiary industry in aluminum manufacture.

The electrolytic step, called the *Hall-Heroult process*, takes place in a graphite-lined furnace, with the lining itself acting as the cathode. Anodes of graphite dip into the molten  $\text{Al}_2\text{O}_3$ - $\text{Na}_3\text{AlF}_6$  mixture (Figure 22.20, *next page*). The cell typically operates at a moderate voltage of 4.5 V, but with an enormous current flow of  $1.0 \times 10^5$  to  $2.5 \times 10^5$  A.

The process is complex and its details are still not entirely known. The specific reactions shown below are among several other possibilities. Molten cryolite contains several ions (including  $\text{AlF}_6^{3-}$ ,  $\text{AlF}_4^-$ , and  $\text{F}^-$ ), which react with  $\text{Al}_2\text{O}_3$  to form fluoro-oxy ions (including  $\text{AlOF}_3^{2-}$ ,  $\text{Al}_2\text{OF}_6^{2-}$ , and  $\text{Al}_2\text{O}_2\text{F}_4^{2-}$ ) that dissolve in the mixture. For example,

$\text{Al}$  forms at the cathode (reduction), shown here with  $\text{AlF}_6^{3-}$  as reactant:

Mining bauxite.

**Figure 22.20** The electrolytic cell in the manufacture of aluminum.

The graphite anodes are oxidized and form carbon dioxide gas. Using one of the fluoro-oxy species as an example, the anode reaction is

Thus, the *graphite anodes themselves are consumed* in this half-reaction and must be replaced frequently.

Combining the three preceding equations and making sure that  $\text{e}^-$  gained at the cathode equal  $\text{e}^-$  lost at the anode gives the overall reaction:

3. *Energy considerations.* The Hall-Heroult process uses an enormous quantity of energy: aluminum production accounts for more than 5% of total U.S. electrical usage. The most basic reason for such high energy consumption is the electron configuration of Al ([Ne]  $3s^23p^1$ ). Each  $\text{Al}^{3+}$  ion needs  $3\text{e}^-$  to form an Al atom, and the atomic mass of Al is so low ( $\sim 27$  g/mol) that 1 mol of  $\text{e}^-$  (96,500 C) produces only 9 g of Al. An aluminum-air battery can turn this disadvantage around. Once produced, Al represents a concentrated form of electrical energy that can deliver a high output per gram: 1 mol of  $\text{e}^-$  for every 9 g of Al consumed in the battery.

**Metallurgy of Aluminum: Uses and Recycling** Aluminum is a superb decorative, functional, and structural metal. It is lightweight, attractive, easy to work, and forms strong alloys. Although Al is very active, it does not corrode readily because of an adherent oxide layer that forms rapidly in air and prevents more  $\text{O}_2$  from penetrating. Nevertheless, when it is in contact with less active metals such as Fe, Cu, and Pb, aluminum becomes the anode in a voltaic-like arrangement and deteriorates rapidly (Section 21.6). To prevent this, aluminum objects are often *anodized*, that is, made to act as the anode in an electrolytic cell that coats them with an oxide layer. The object is immersed in a 20%  $\text{H}_2\text{SO}_4$  bath and connected to a graphite cathode:

**Figure 22.21** The many familiar and essential uses of aluminum.

The  $\text{Al}_2\text{O}_3$  layer deposited is typically from  $10\ \mu$  to  $100\ \mu$  thick, depending on the object's intended use. Figure 22.21 presents a breakdown of the many uses of aluminum.

More than 4.0 billion pounds (1.8 million metric tons) of aluminum cans and packaging are discarded each year—a waste of one of the most useful materials in the world *and* the energy used to make it. A quick calculation of the energy needed to prepare 1 mol of Al from *purified*  $\text{Al}_2\text{O}_3$ , compared with the energy needed for recycling, conveys a clear message. For the overall cell reaction in the Hall-Heroult process,  $\Delta H^\circ = 2272\ \text{kJ}$  and  $\Delta S^\circ = 635.4\ \text{J/K}$ . If we consider *only* the standard free energy change of the reaction at  $1000.^\circ\text{C}$ , for 1 mol of Al, we obtain

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = \frac{2272\ \text{kJ}}{4\ \text{mol Al}} - \left(1273\ \text{K} \times \frac{0.6354\ \text{kJ/K}}{4\ \text{mol Al}}\right) = 365.8\ \text{kJ/mol Al}$$

The molar mass of Al is nearly 2.5 times the mass of a soft-drink or beer can, so the electrolysis step requires nearly 150 kJ of energy for each can!

When aluminum is recycled, the major energy input (which is for melting the cans and foil) has been calculated as  $\sim 26\ \text{kJ/mol Al}$ . The ratio of these energy inputs is

$$\frac{\text{Energy to recycle 1 mol Al}}{\text{Energy for electrolysis of 1 mol Al}} = \frac{26\ \text{kJ}}{365.8\ \text{kJ}} = 0.071$$

Based on just these portions of the process, recycling uses about 7% as much energy as electrolysis. Recent energy estimates for the entire manufacturing process (including mining, pretreating, maintaining operating conditions, electrolyzing, and so forth) are about  $6000\ \text{kJ/mol Al}$ , which means recycling requires less than 1% as much energy as manufacturing. The economic advantages, not to mention the environmental ones, are obvious, and recycling of aluminum has become common in the United States (*see photo*).

## Mining the Sea for Magnesium

As terrestrial sources of certain elements become scarce or too costly to mine, the oceans will become an important source. In fact, despite the abundant distribution of magnesium on land, it is already obtained from the sea.

**Isolation of Magnesium** The *Dow process* for isolating magnesium from the sea involves steps similar to those used for rocky ores (Figure 22.22, *next page*):

1. *Mining*. Intake of seawater and straining the debris are the “mining” steps. No pretreatment is needed.

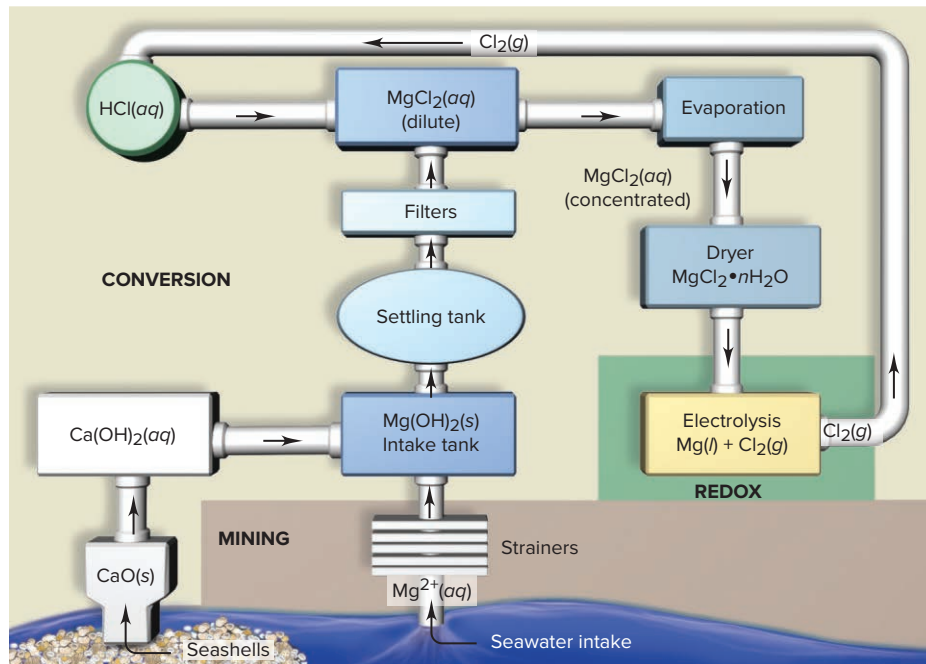

2. *Converting to mineral*. The dissolved  $\text{Mg}^{2+}$  ion is converted to the mineral  $\text{Mg}(\text{OH})_2$  with  $\text{Ca}(\text{OH})_2$ , which is generated on-site (at the plant). Seashells ( $\text{CaCO}_3$ ) are crushed, decomposed to  $\text{CaO}$  by heating, and mixed with water to make slaked lime [ $\text{Ca}(\text{OH})_2$ ]. This is pumped into the intake tank to precipitate the  $\text{Mg}^{2+}$  as the hydroxide ( $K_{\text{sp}} \approx 10^{-9}$ ):

Crushed aluminum cans ready for recycling.

Source: © Monty Rakusen/Cultura/Getty Images RF

**Figure 22.22** The Dow process for isolation of elemental Mg from seawater.

3. *Converting to compound.* The solid  $\text{Mg}(\text{OH})_2$  is filtered and mixed with excess HCl, which is also made on-site, to form aqueous  $\text{MgCl}_2$ :

The water is evaporated in stages to give solid, hydrated  $\text{MgCl}_2 \cdot n\text{H}_2\text{O}$ .

4. *Electrochemical redox.* Heating above  $700^\circ\text{C}$  drives off the water of hydration and melts the  $\text{MgCl}_2$ . Electrolysis gives chlorine gas and the molten metal, which floats on the denser molten salt:

The  $\text{Cl}_2$  that forms is recycled to make the HCl used in step 3.

**Uses of Magnesium** Magnesium is the lightest structural metal available (about one-half the density of Al and one-fifth that of steel). Although Mg is quite reactive, it forms an extremely adherent, high-melting oxide layer ( $\text{MgO}$ ) that prevents further reaction with the free metal beneath it; thus, magnesium finds many uses in metal alloys and can be machined into any form. Magnesium alloys occur in everything from aircraft bodies to camera bodies, and from luggage to auto engine blocks. The pure metal is a strong reducing agent, which makes it useful for sacrificial anodes (Section 21.6) and in the metallurgical extraction of other metals, such as Be, Ti, Zr, Hf, and U. For example, titanium, an essential component of jet engines (*see photo*), is made from its major ore, ilmenite, in two steps:

## The Sources and Uses of Hydrogen

Although hydrogen accounts for 90% of the atoms in the universe, it makes up only 15% of the atoms in Earth's crust. Moreover, hydrogen exists elsewhere in the universe mostly as  $\text{H}_2$  molecules and free H atoms, but virtually all hydrogen in the crust is combined with other elements, either oxygen in natural waters or carbon in biomass and petroleum.

**Industrial Production of Hydrogen** Hydrogen gas ( $\text{H}_2$ ) is produced on an industrial scale worldwide: 250,000 metric tons ( $3 \times 10^{12}$  L at STP; equivalent to  $\sim 1 \times 10^{11}$  mol)

Jet engine assembly.

Source: © Ken Whitmore/Getty Images

are produced annually in the United States alone. All production methods are energy intensive, so the choice is determined by energy costs. In Scandinavia, where hydroelectric power is plentiful, electrolysis is used; on the other hand, where natural gas from oil refineries is plentiful, as in the United States and Great Britain, thermal methods are used.

1. *Electrolysis.* Very pure  $\text{H}_2$  is prepared through electrolysis of water with Pt (or Ni) electrodes:

Overvoltage makes the cell potential about  $-2 \text{ V}$  (Section 21.7). Therefore, under typical operating conditions, it takes about 400 kJ of energy to produce 1 mol of  $\text{H}_2$ :

$$\Delta G = -nFE = (-2 \text{ mol } e^-) \left( \frac{96.5 \text{ kJ}}{\text{V} \cdot \text{mol } e^-} \right) (-2 \text{ V}) = 4 \times 10^2 \text{ kJ/mol } \text{H}_2$$

High-purity  $\text{O}_2$  is a valuable byproduct of this process that offsets some of the costs of isolating  $\text{H}_2$ .

2. *Thermal methods.* The most common thermal methods use water and a simple alkane like methane, which has the highest H/C atom ratio of any hydrocarbon. The reactants are heated to around  $1000^\circ\text{C}$  over a nickel-based catalyst in the endothermic *steam-reforming process*:

Heat is supplied by burning methane. To generate more  $\text{H}_2$ , the product mixture (called *water gas*) is heated with steam at  $400^\circ\text{C}$  over an iron or cobalt oxide catalyst in the exothermic *water-gas shift reaction*, and the CO reacts (see also Chemical Connections at the end of Section 6.6):

The reaction mixture is recycled several times, which decreases the CO to around 0.2% by volume. Passing the mixture through liquid water removes the more soluble  $\text{CO}_2$  (solubility = 0.034 mol/L), leaving a higher proportion of  $\text{H}_2$  (solubility < 0.001 mol/L). Calcium oxide can also be used to remove  $\text{CO}_2$  by formation of  $\text{CaCO}_3$ . By removing  $\text{CO}_2$ , these steps shift the equilibrium position to the right and produce  $\text{H}_2$  that is about 98% pure. To filter out nearly all molecules larger than  $\text{H}_2$  and attain greater purity ( $\sim 99.9\%$ ), the gas mixture is passed through a *synthetic zeolite*. This material is an aluminosilicate whose framework of polyhedra contains small cavities of various sizes that trap some molecules and allow others to pass through.

**Industrial Uses of Hydrogen** Typically, an industrial plant produces  $\text{H}_2$  to make some other product. More than 95% of the  $\text{H}_2$  produced is consumed in ammonia or petrochemical facilities.

1. *Ammonia synthesis.* In a plant that synthesizes  $\text{NH}_3$ , the reactant gases,  $\text{N}_2$  and  $\text{H}_2$ , are formed through a series of reactions that involve methane. Here is a typical reaction series in an ammonia plant:

- The steam-reforming reaction is performed with excess  $\text{CH}_4$ , which depletes the reaction mixture of  $\text{H}_2\text{O}$ :

- An excess of the product mixture ( $\text{CH}_4$ ,  $\text{CO}$ , and  $\text{H}_2$ ) is burned in an amount of air ( $\text{N}_2$  +  $\text{O}_2$ ) that is insufficient for complete combustion, but is enough to consume the  $\text{O}_2$ , heat the mixture to  $1100^\circ\text{C}$ , and form additional  $\text{H}_2\text{O}$ :

- Any remaining  $\text{CH}_4$  reacts by the steam-reforming reaction, the remaining CO reacts by the water-gas shift reaction ( $\text{H}_2\text{O} + \text{CO} \rightleftharpoons \text{CO}_2 + \text{H}_2$ ) to form more  $\text{H}_2$ , and then the  $\text{CO}_2$  is removed with CaO ( $\text{CaO} + \text{CO}_2 \rightarrow \text{CaCO}_3$ ).
- The amounts are carefully adjusted to produce a final mixture that contains a 1/3 mole ratio of  $\text{N}_2$  (from the added air) to  $\text{H}_2$  (with traces of  $\text{CH}_4$ , Ar, and CO). This mixture is used directly in the synthesis of ammonia (Section 17.6).

2. *Hydrogenation.* A second major use of  $\text{H}_2$  is *hydrogenation* of  $\text{C}=\text{C}$  bonds in liquid oils to form  $\text{C}-\text{C}$  bonds in solid fats and margarine. The process uses  $\text{H}_2$  in contact with transition metal catalysts, such as powdered nickel (see Figure 16.25). Solid fats are also used in commercial baked goods. Look at the list of ingredients on most packages of bread, cake, and cookies, and you'll see the “partially hydrogenated vegetable oils” made by this process.

3. *Bulk chemicals and energy production.* Hydrogen is also essential in the manufacture of numerous “bulk” chemicals, those produced in large amounts because they have many further uses. One application that has been gaining great attention is the production of methanol. In this process, carbon monoxide reacts with hydrogen over a copper–zinc oxide catalyst:

Methanol is already being used as a gasoline additive. As less expensive sources become available, hydrogen will also be used increasingly in fuel cells on a major scale (Section 21.5).

**Production and Uses of Deuterium; Kinetic Isotope Effect** In addition to ordinary hydrogen ( $^1\text{H}$ ), or protium, there are two other naturally occurring isotopes of significantly lower abundance. Deuterium ( $^2\text{H}$  or D) has one neutron, and rare, radioactive tritium ( $^3\text{H}$  or T) has two. Like  $\text{H}_2$ , both occur as diatomic molecules:  $\text{D}_2$  (or  $^2\text{H}_2$ ) and  $\text{T}_2$  (or  $^3\text{H}_2$ ). Table 22.6 compares some of their molecular and physical properties. As you can see from these data, the heavier the isotope is and, thus, the higher the molar mass of the molecule, the higher the melting point, boiling point, and heats of phase change.

Because hydrogen is so light, the relative difference in mass of its isotopes is enormous compared with that of isotopes of other common, heavier elements. For example,  $^2\text{H}$  has 2 times the mass of  $^1\text{H}$ , whereas  $^{13}\text{C}$  has only 1.08 times the mass of  $^{12}\text{C}$ . *The mass difference leads to different bond energies, which affect reactivity.* As a result, an H atom bonded to a given atom vibrates at a higher frequency than a D atom does, so the bond to H is higher in energy. Thus, *it is weaker and easier to break.* Therefore, any reaction that includes breaking a bond to H or D in the rate-determining step occurs *faster with H than with D.* This phenomenon, called a *kinetic isotope effect*, is also used to isolate deuterium.

Deuterium and its compounds are produced from  $\text{D}_2\text{O}$  (heavy water), which is present as a minor component (0.016 mol %) in normal water and is isolated on the

**Table 22.6** Some Molecular and Physical Properties of Diatomic Protium, Deuterium, and Tritium

Property	$\text{H}_2$	$\text{D}_2$	$\text{T}_2$
Molar mass (g/mol)	2.016	4.028	6.032
Bond length (pm)	74.14	74.14	74.14
Melting point (K)	13.96	18.73	20.62
Boiling point (K)	20.39	23.67	25.04
$\Delta H_{\text{fus}}^\circ$ (kJ/mol)	0.117	0.197	0.250
$\Delta H_{\text{vap}}^\circ$ (kJ/mol)	0.904	1.226	1.393
Bond energy (kJ/mol at 298 K)	432	443	447

multiton scale by *electrolytic enrichment*. Due to the kinetic isotope effect, there is a *higher rate of bond breaking for O—H bonds compared to O—D bonds*, and thus a higher rate of electrolysis of H<sub>2</sub>O compared with D<sub>2</sub>O.

For example, with Pt electrodes, H<sub>2</sub>O is electrolyzed about 14 times faster than D<sub>2</sub>O. As some of the liquid decomposes to the elemental gases, the remainder becomes enriched in D<sub>2</sub>O. Thus, by the time the volume of water has been reduced to 1/20,000 of its original volume, the remaining water is around 99% D<sub>2</sub>O. By combining samples and repeating the electrolysis, water that is more than 99.9% D<sub>2</sub>O is obtained.

Deuterium gas is produced by electrolysis of D<sub>2</sub>O or by any of the chemical reactions that produce hydrogen gas from water, such as

Compounds containing deuterium (or tritium) are produced from reactions that give rise to the corresponding hydrogen-containing compound; for example,

Compounds with acidic protons undergo hydrogen/deuterium exchange:

We discuss the natural and synthetic formation of tritium in Chapter 24.

## › Summary of Section 22.4

Production highlights of key elements are as follows:

- › Na is isolated by electrolysis of molten NaCl in the Downs process; Cl<sub>2</sub> is a byproduct.
- › K is produced by reduction with Na in a thermal process.
- › Fe is produced through a multistep high-temperature process in a blast furnace. The crude pig iron is converted to carbon steel in the basic-oxygen process and then alloyed with other metals to make different steels.
- › Cu is produced by concentration of the ore through flotation, reduction to the metal by smelting, and purification by electrorefining. The metal has extensive electrical and plumbing uses.
- › Al is extracted from bauxite by pretreating the ore with concentrated base, followed by electrolysis of the product Al<sub>2</sub>O<sub>3</sub> mixed with molten cryolite. Al alloys are widely used in homes and industry. The total energy required to extract Al from its ore is over 100 times that needed for recycling it.
- › The Mg<sup>2+</sup> in seawater is converted to Mg(OH)<sub>2</sub> and then to MgCl<sub>2</sub>, which is electrolyzed to obtain the metal; Mg forms strong, lightweight alloys.
- › H<sub>2</sub> is produced by electrolysis of water or in the formation of gaseous fuels from hydrocarbons. It is used in NH<sub>3</sub> production, in hydrogenation of vegetable oils, and in energy production. The isotopes of hydrogen differ significantly in atomic mass and thus in the rate at which their bonds to other atoms break (kinetic isotope effect). This difference is used to obtain D<sub>2</sub>O from water.

## 22.5 CHEMICAL MANUFACTURING: TWO CASE STUDIES

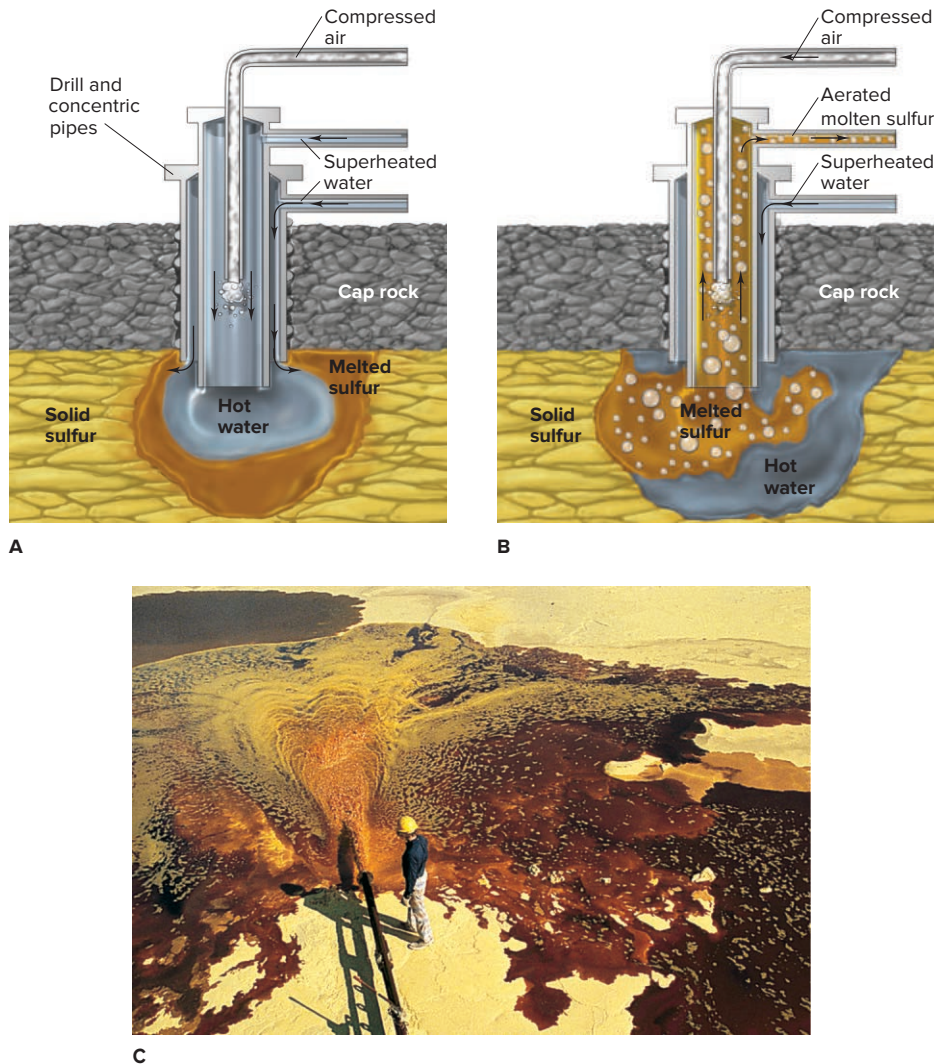

In this final section, we examine the interplay of theory and practice in two of the most important processes in the inorganic chemical industry: the contact process for the production of sulfuric acid and the chlor-alkali process for the production of chlorine.

### Sulfuric Acid, the Most Important Chemical

Because it has countless uses, sulfuric acid is produced throughout the world on a gigantic scale—more than 150 million tons a year. The modern **contact process** is based on the *catalyzed oxidation of SO<sub>2</sub>*. Here are the key steps.

**Figure 22.23** The Frasch process for mining elemental sulfur.

Source: (C) © Nathan Benn/Corbis

1. *Obtaining sulfur.* In most countries today, the production of sulfuric acid starts with the production of elemental sulfur, often by the *Claus process*, in which the  $\text{H}_2\text{S}$  in “sour” natural gas is chemically separated and then oxidized:

Where natural deposits of sulfur are found, it is obtained by a nonchemical method called the *Frasch process*. A hole is drilled to the deposit, and superheated water (about  $160^\circ\text{C}$ ) is pumped down two outer concentric pipes to melt the sulfur (Figure 22.23A). Then, a combination of the hydrostatic pressure in an outermost pipe and the pressure of compressed air sent through a narrow inner pipe forces the sulfur to the surface (Figure 22.23B and C). The costs of drilling, pumping, and supplying water ( $5 \times 10^6$  gallons per day) are balanced somewhat by the purity of the product ( $\sim 99.7\%$  sulfur). About 90% of processed sulfur is used in making sulfur dioxide for production of sulfuric acid. Indeed, this end product is so important that a nation’s level of sulfur production is a reliable indicator of its overall industrial capacity: the United States, Canada, China, Russia, Japan, and Germany are the top six sulfur producers.

2. *From sulfur to sulfur dioxide.* The sulfur is burned in air to form  $\text{SO}_2$ :

Some  $\text{SO}_2$  is also obtained by roasting metal sulfide ores and from the Claus process.

3. *From sulfur dioxide to trioxide.* The contact process oxidizes  $\text{SO}_2$  to  $\text{SO}_3$ :

The reaction is *exothermic* and very *slow* at room temperature. From Le Châtelier's principle (Section 17.6), the yield of  $\text{SO}_3$  can be increased by (1) changing the temperature, (2) increasing the pressure (more moles of gas are on the left than on the right), or (3) adjusting the concentrations (adding excess  $\text{O}_2$  and removing  $\text{SO}_3$ ). In this case, the pressure effect is small and economically not worth exploiting. Let's examine the other two effects:

- *Effect of changing the temperature.* Adding heat (raising the temperature) increases the frequency and energy of  $\text{SO}_2$ - $\text{O}_2$  collisions and thus increases the *rate* of  $\text{SO}_3$  formation. However, because the formation is exothermic, removing heat (lowering the temperature) shifts the equilibrium position to the right and thus increases the *yield* of  $\text{SO}_3$ . This is a classic situation that calls for use of a catalyst. By lowering the activation energy, a catalyst allows equilibrium to be reached more quickly and at a lower temperature; thus, rate and yield are optimized (Section 16.7). The catalyst in the contact process is  $\text{V}_2\text{O}_5$  on inert silica, which is active between  $400^\circ\text{C}$  and  $600^\circ\text{C}$ .
- *Effect of changing the concentration.* Providing an excess of  $\text{O}_2$  as a 5/1 mixture of air to  $\text{SO}_2$ , which is about 1/1  $\text{O}_2$  to  $\text{SO}_2$ , supplies about twice as much  $\text{O}_2$  as in the balanced equation. The mixture is passed over catalyst beds in four stages, and the  $\text{SO}_3$  is removed to shift the reaction toward more  $\text{SO}_3$  formation. The overall yield of  $\text{SO}_3$  is 99.5%.

4. *From sulfur trioxide to acid.* Sulfur trioxide is the anhydride of sulfuric acid. However,  $\text{SO}_3$  cannot be added to water because, at the operating temperature, it would first meet water vapor, which catalyzes its polymerization to  $(\text{SO}_3)_x$ , and results in a smoke of solid particles that yields little acid (reaction 1). To avoid this, previously formed  $\text{H}_2\text{SO}_4$  absorbs the  $\text{SO}_3$  (reaction 2) and forms pyrosulfuric acid (or disulfuric acid,  $\text{H}_2\text{S}_2\text{O}_7$ ; see margin), which is then hydrolyzed with sufficient water (reaction 3):

The industrial uses of sulfuric acid are legion, as Figure 22.24 indicates.

Sulfuric acid is remarkably inexpensive (about \$150/ton), largely because each step in the process is exothermic—burning S ( $\Delta H^\circ = -297 \text{ kJ/mol}$ ), oxidizing  $\text{SO}_2$  ( $\Delta H^\circ = -99 \text{ kJ/mol}$ ), hydrating  $\text{SO}_3$  ( $\Delta H^\circ = -132 \text{ kJ/mol}$ )—and the heat is a valuable

disulfuric acid

Figure 22.24 The many indispensable applications of sulfuric acid.

byproduct. Three-quarters of the heat is sold as steam, and the rest of it is used to pump gases through the plant. A typical plant making 825 tons of  $\text{H}_2\text{SO}_4$  per day produces enough steam to generate  $7 \times 10^6$  watts of electric power.

## The Chlor-Alkali Process

Chlorine is produced and used in amounts many times greater than all the other halogens combined, ranking among the top 10 chemicals produced in the United States. The **chlor-alkali process**, which forms the basis of one of the largest inorganic chemical industries, *electrolyzes concentrated aqueous NaCl to produce  $\text{Cl}_2$* , along with several other important chemicals. There are three versions of this process.

**Diaphragm-Cell Method** As you learned in Section 21.7, the electrolysis of aqueous NaCl does not yield both of the component elements. Because of the overvoltage,  $\text{Cl}^-$  ions rather than  $\text{H}_2\text{O}$  molecules are oxidized at the anode. However,  $\text{Na}^+$  ions are not reduced at the cathode because the half-cell potential ( $-2.71$  V) is much more negative than that for reduction of  $\text{H}_2\text{O}$  ( $-0.42$  V), even with the normal overvoltage (around  $-0.6$  V). Therefore, the half-reactions for electrolysis of aqueous NaCl are

To obtain commercially meaningful amounts of  $\text{Cl}_2$ , however, a voltage almost twice this value and a current in excess of  $3 \times 10^4$  A are used.

When we include the spectator ion  $\text{Na}^+$ , the total ionic equation shows that the process yields another important product, NaOH:

As Figure 22.25 shows, the sodium salts in the cathode compartment exist as an aqueous mixture of NaCl and NaOH; the NaCl is removed by fractional crystallization. Thus, in this version of the chlor-alkali process, which uses an *asbestos diaphragm* to separate the anode and cathode compartments, electrolysis of NaCl brines yields  $\text{Cl}_2$ ,  $\text{H}_2$ , and industrial-grade NaOH, a useful base. Like other reactive products,  $\text{H}_2$  and  $\text{Cl}_2$  are kept apart to prevent explosive recombination. Note the higher liquid level in the anode (*left*) compartment. This slight hydrostatic pressure difference minimizes backflow of NaOH, which prevents the disproportionation reactions of  $\text{Cl}_2$  that occur in the presence of  $\text{OH}^-$  (Section 14.9), such as

**Figure 22.25** A diaphragm cell for the chlor-alkali process.

**Mercury-Cell Method** If high-purity NaOH is desired, a slightly different version, called the *chlor-alkali mercury-cell process*, is employed. Mercury is used as the cathode, which creates such a large overvoltage for reduction of H<sub>2</sub>O to H<sub>2</sub> that the process *does* favor reduction of Na<sup>+</sup>. The sodium dissolves in the mercury to form sodium amalgam, Na(Hg). In the mercury-cell version, the half-reactions are

To obtain sodium hydroxide, the sodium amalgam is pumped out of the system and treated with H<sub>2</sub>O, which is reduced by the Na:

The mercury released in this step is recycled back to the electrolysis bath. Therefore, *the products are the same in both versions* of the chlor-alkali process, but the purity of NaOH from the mercury-cell method is much higher.

The mercury-cell method is being steadily phased out because, as the mercury is recycled, small amounts are lost in the industrial wastewater. On average, 200 g of Hg is lost per ton of Cl<sub>2</sub> produced. In the 1980s, annual U.S. production via the mercury-cell method was 2.75 million tons of Cl<sub>2</sub>; thus, during that decade, 550,000 kg of mercury, a toxic heavy metal, was flowing into U.S. waterways each year!

**Membrane-Cell Method** The *chlor-alkali membrane-cell process* replaces the asbestos diaphragm used in the diaphragm-cell method to separate the cell compartments with a polymeric membrane. The membrane allows only cations to move through it and only from anode to cathode compartments. Thus, as Cl<sup>-</sup> ions are removed at the anode through oxidation to Cl<sub>2</sub>, Na<sup>+</sup> ions in the anode compartment move through the membrane to the cathode compartment and form an NaOH solution. In addition to forming purer NaOH than the older diaphragm-cell method, the membrane-cell method uses less electricity and eliminates the problem of Hg pollution. As a result, it has been adopted throughout much of the industrialized world.

## › Summary of Section 22.5

- › Sulfuric acid production starts with the extraction of sulfur, either by the oxidation of H<sub>2</sub>S or the mining of sulfur deposits. The sulfur is roasted to SO<sub>2</sub> and oxidized to SO<sub>3</sub> by the catalyzed contact process, which optimizes the yield at lower temperatures. Absorption of the SO<sub>3</sub> into H<sub>2</sub>SO<sub>4</sub>, followed by hydration, forms sulfuric acid.
- › In the diaphragm-cell method for the chlor-alkali process, aqueous NaCl is electrolyzed to form Cl<sub>2</sub>, H<sub>2</sub>, and low-purity NaOH. The mercury-cell method produces high-purity NaOH but has been almost completely phased out because of mercury pollution. The membrane-cell method requires less electricity and does not use Hg.

## CHAPTER REVIEW GUIDE

### Learning Objectives

Relevant section (§) numbers appear in parentheses.

#### Understand These Concepts

1. How gravity, thermal convection, and elemental properties led to the silicate, sulfide, and iron phases and the predominance of certain elements in Earth's crust, mantle, and core (§22.1)
2. How organisms affect crustal abundances of elements, especially oxygen, carbon, calcium, and some transition metals; the onset of oxidation as an energy source (§22.1)
3. How atomic properties influence which elements have oxide ores and which have sulfide ores (§22.1)
4. The central role of CO<sub>2</sub> and the importance of photosynthesis, respiration, and decomposition in the carbon cycle (§22.2)
5. The central role of N<sub>2</sub> and the importance of atmospheric, industrial, and biological fixation in the nitrogen cycle (§22.2)
6. The absence of a gaseous component and the interactions of the inorganic and biological cycles in the phosphorus cycle; the impact of humans on this cycle (§22.2)
7. How pyro-, electro-, and hydrometallurgical processes are employed to extract a metal from its ore; the importance of the reduction step from compound to metal; refining and alloying processes (§22.3)
8. Functioning of the Downs cell for Na production and the application of Le Châtelier's principle to K production (§22.4)

## Learning Objectives (continued)

Relevant section (§) numbers appear in parentheses.

- How iron ore is reduced in a blast furnace and how pig iron is purified by the basic-oxygen process (§22.4)
- How Fe is removed from copper ore and impure Cu is electrorefined (§22.4)
- The importance of amphoterism in the Bayer process for isolating  $\text{Al}_2\text{O}_3$  from bauxite; the significance of cryolite in the electrolytic step; the energy advantage of Al recycling (§22.4)
- The steps in the Dow process for the extraction of Mg from seawater (§22.4)
- How  $\text{H}_2$  production, whether by chemical or electrolytic means, is tied to  $\text{NH}_3$  production (§22.4)
- How the kinetic isotope effect is applied to produce deuterium (§22.4)
- How the Frasch process is used to obtain sulfur from natural deposits (§22.5)
- The importance of equilibrium and kinetic factors in  $\text{H}_2\text{SO}_4$  production (§22.5)
- How overvoltage allows electrolysis of aqueous NaCl to form  $\text{Cl}_2$  gas in the chlor-alkali process; coproduction of NaOH; comparison of diaphragm-cell, mercury-cell, and membrane-cell methods (§22.5)

## Key Terms

Page numbers appear in parentheses.

abundance (997)	chlor-alkali process (1028)	fixation (1003)	mineral (1008)
alloy (1012)	contact process (1025)	flotation (1009)	occurrence (source) (1000)
apatites (1005)	core (998)	gangue (1008)	ore (1001)
atmosphere (999)	crust (998)	hydrosphere (999)	roasting (1010)
basic-oxygen process (1017)	differentiation (998)	leaching (1009)	slag (1017)
biosphere (999)	Downs cell (1014)	lithosphere (999)	smelting (1010)
blast furnace (1016)	electrorefining (1012)	mantle (998)	steel (1016)
carbon steel (1017)	environmental cycle (1002)	metallurgy (1008)	zone refining (1012)

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and offer Concept Review Questions and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

## How the Elements Occur in Nature

## Concept Review Questions

**22.1** Hydrogen is by far the most abundant element cosmically. In interstellar space, it exists mainly as  $\text{H}_2$ . In contrast, on Earth, it exists very rarely as  $\text{H}_2$  and is ninth in abundance in the crust. Why is hydrogen so abundant in the universe? Why is hydrogen so rare as a diatomic gas in Earth's atmosphere?

**22.2** Metallic elements can be recovered from ores that are oxides, carbonates, halides, or sulfides. Give an example of each type.

**22.3** The location of elements in the regions of Earth has enormous practical importance. (a) Define *differentiation*, and explain which physical property of a substance is primarily responsible for this process. (b) What are the four most abundant elements in the crust? (c) Which element is abundant in the crust and mantle but not the core?

**22.4** How does the position of a metal in the periodic table relate to whether it occurs primarily as an oxide or as a sulfide in nature?

## Problems in Context

**22.5** What material is the source for commercial production of each of the following elements: (a) aluminum; (b) nitrogen; (c) chlorine; (d) calcium; (e) sodium?

**22.6** Aluminum is widely distributed throughout the world in the form of aluminosilicates. What property of these minerals prevents them from being a source of aluminum?

**22.7** Describe two ways in which the biosphere has influenced the composition of Earth's crust.

## The Cycling of Elements Through the Environment

## Concept Review Questions

**22.8** Use atomic and molecular properties to explain why life is based on carbon rather than some other element, such as silicon.

**22.9** Define *fixation*. Name two elements that undergo environmental fixation. What natural forms of them are fixed?

**22.10** Carbon dioxide enters the atmosphere by natural processes and from human activity. Why is the latter a cause of concern?

**22.11** Diagrams of environmental cycles are simplified to omit minor contributors. For example, the production of lime from limestone is not shown in the cycle for carbon (Figure 22.5). Which labeled category in the figure includes this process? Name two other processes that contribute to this category.

**22.12** Describe three pathways for the fixation of atmospheric nitrogen. Is human activity a significant factor? Explain.

**22.13** Why don't the N-containing species in Figure 22.6 include rings or long chains with N—N bonds?

**22.14** (a) Which region of Earth's crust is not involved in the phosphorus cycle? (b) Name two roles organisms play in the cycle.

**Problems in Context**

**22.15** Nitrogen fixation requires a great deal of energy because the  $N_2$  bond is strong.

(a) How do the processes of atmospheric and industrial fixation reflect this energy requirement?

(b) How do the thermodynamics of the two processes differ? (*Hint:* Examine the respective heats of formation.)

(c) In view of the mild conditions for biological fixation, what must be the source of the “great deal of energy”? (d) What would be the most obvious environmental result of a low activation energy for  $N_2$  fixation?

**22.16** The following steps are *unbalanced* half-reactions involved in the nitrogen cycle. Balance each half-reaction to show the number of electrons lost or gained, and state whether it is an oxidation or a reduction (all occur in acidic conditions):

**22.17** The use of silica to form slag in the production of phosphorus from phosphate rock was introduced by Robert Boyle more than 300 years ago. When fluorapatite  $[Ca_5(PO_4)_3F]$  is used in phosphorus production, most of the fluorine atoms appear in the slag, but some end up in the toxic and corrosive gas  $SiF_4$ .

(a) If 15% by mass of the fluorine in 100. kg of  $Ca_5(PO_4)_3F$  forms  $SiF_4$ , what volume of this gas is collected at 1.00 atm and the industrial furnace temperature of 1450.°C?

(b) In some facilities, the  $SiF_4$  is used to produce sodium hexafluorosilicate ( $Na_2SiF_6$ ) which is sold for water fluoridation:

How many cubic meters of drinking water can be fluoridated to a level of 1.0 ppm of  $F^-$  using the  $SiF_4$  produced in part (a)?

**22.18** An impurity sometimes found in  $Ca_3(PO_4)_2$  is  $Fe_2O_3$ , which is removed during the production of phosphorus as *ferrophosphorus* ( $Fe_2P$ ). (a) Why is this impurity troubling from an economic standpoint? (b) If 50. metric tons (t) of crude  $Ca_3(PO_4)_2$  contain 2.0%  $Fe_2O_3$  by mass and the overall yield of phosphorus is 90.%, how many metric tons of  $P_4$  can be isolated?

**Metallurgy: Extracting a Metal from Its Ore****Concept Review Questions**

**22.19** Define: (a) ore; (b) mineral; (c) gangue; (d) brine.

**22.20** Define: (a) roasting; (b) smelting; (c) flotation; (d) refining.

**22.21** What factors determine which reducing agent is selected for producing a specific metal?

**22.22** Use atomic properties to explain the reduction of a less active metal by a more active one: (a) in aqueous solution; (b) in the molten state. Give a specific example of each process.

**22.23** What class of element is obtained by oxidation of a mineral? What class of element is obtained by reduction of a mineral?

**Problems in Context**

**22.24** Which set of elements gives each of the following alloys: (a) brass; (b) stainless steel; (c) bronze; (d) sterling silver?

1. Cu, Ag
2. Cu, Sn, Zn
3. Ag, Au
4. Fe, Cr, Ni
5. Fe, V
6. Cu, Zn

**Tapping the Crust: Isolation and Uses of Selected Elements****Concept Review Questions**

**22.25** How are each of the following involved in iron metallurgy: (a) slag; (b) pig iron; (c) steel; (d) basic-oxygen process?

**22.26** What are the distinguishing features of each extraction process: pyrometallurgy, electrometallurgy, and hydrometallurgy? Explain briefly how the types of metallurgy are used in the production of (a) Fe; (b) Na; (c) Au; (d) Al.

**22.27** What property allows copper to be purified in the presence of iron and nickel impurities? Explain.

**22.28** Why is cryolite used in the electrolysis of aluminum oxide?

**22.29** (a) What is a kinetic isotope effect?

(b) Do compounds of hydrogen exhibit a relatively large or small kinetic isotope effect? Explain.

(c) Carbon compounds also exhibit a kinetic isotope effect. How do you expect it to compare in magnitude with that for hydrogen compounds? Why?

**22.30** How is Le Châtelier’s principle involved in the production of elemental potassium?

**Problems in Context**

**22.31** Elemental Li and Na are prepared by electrolysis of a molten salt, whereas K, Rb, and Cs are prepared by chemical reduction.

(a) In general terms, explain why the alkali metals cannot be prepared by electrolysis of their aqueous salt solutions.

(b) Use ionization energies (see the Family Portraits for Group 1A(1) in Section 14.3 and for Group 2A(2) in Section 14.4) to explain why calcium should *not* be able to isolate Rb from molten  $RbX$  ( $X = \text{halide}$ ).

(c) Use physical properties to explain why calcium *is* used to isolate Rb from molten  $RbX$ .

(d) Can Ca be used to isolate Cs from molten  $CsX$ ? Explain.

**22.32** A Downs cell operating at 77.0 A produces 31.0 kg of Na.

(a) What volume of  $Cl_2(g)$  is produced at 1.0 atm and 540.°C?

(b) How many coulombs were passed through the cell?

(c) How long did the cell operate?

**22.33** (a) In the industrial production of iron, what is the reducing substance loaded into the blast furnace?

(b) In addition to furnishing the reducing power, what other function does this substance serve?

(c) What is the formula of the active reducing agent in the process?

(d) Write equations for the stepwise reduction of  $Fe_2O_3$  to iron in the furnace.

**22.34** One of the substances loaded into a blast furnace is limestone, which produces lime in the furnace.

(a) Give the chemical equation for the reaction forming lime.

(b) Explain the purpose of lime in the furnace. The term *flux* is often used as a label for a substance acting as the lime does. What is the derivation of this word, and how does it relate to the function of the lime?

(c) Write a chemical equation describing the action of lime flux.

**22.35** The last step in the Dow process for the production of magnesium metal involves electrolysis of molten  $MgCl_2$ .

(a) Why isn’t the electrolysis carried out with aqueous  $MgCl_2$ ? What are the products of this aqueous electrolysis?

(b) Do the high temperatures required to melt  $MgCl_2$  favor products or reactants? (*Hint:* Consider the  $\Delta H_f^\circ$  of  $MgCl_2$ .)

**22.36** Iodine is the only halogen that occurs in a positive oxidation state, in  $\text{NaIO}_3$  impurities within Chile saltpeter,  $\text{NaNO}_3$ .

(a) Is this mode of occurrence consistent with iodine's location in the periodic table? Explain.

(b) In the production of  $\text{I}_2$ ,  $\text{IO}_3^-$  reacts with  $\text{HSO}_3^-$ :

Identify the oxidizing and reducing agents.

(c) If 0.78 mol % of an  $\text{NaNO}_3$  deposit is  $\text{NaIO}_3$ , how much  $\text{I}_2$  (in g) can be obtained from 1.000 ton (2000. lb) of the deposit?

**22.37** Selenium is prepared by the reaction of  $\text{H}_2\text{SeO}_3$  with gaseous  $\text{SO}_2$ .

(a) What redox process does the sulfur dioxide undergo? What is the oxidation state of sulfur in the product?

(b) Given that the reaction occurs in acidic aqueous solution, what is the formula of the sulfur-containing species?

(c) Write the balanced redox equation for the process.

**22.38**  $\text{F}_2$  and  $\text{Cl}_2$  are produced by electrolytic oxidation, whereas  $\text{Br}_2$  and  $\text{I}_2$  are produced by chemical oxidation of the halide ions in a concentrated aqueous solution (brine) by a more electronegative halogen. Give two reasons why  $\text{Cl}_2$  isn't prepared this way.

**22.39** Silicon is prepared by the reduction of  $\text{K}_2\text{SiF}_6$  with Al. Write the equation for this reaction. (*Hint*: Can  $\text{F}^-$  be oxidized in this reaction? Can  $\text{K}^+$  be reduced?)

**22.40** What is the mass percent of iron in each of the following iron ores:  $\text{Fe}_2\text{O}_3$ ,  $\text{Fe}_3\text{O}_4$ ,  $\text{FeS}_2$ ?

**22.41** Phosphorus is one of the impurities present in pig iron that is removed in the basic-oxygen process. Assuming that phosphorus is present as P atoms, write equations for its oxidation and subsequent reaction in the basic slag.

**22.42** The final step in the smelting of  $\text{CuFeS}_2$  is

(a) Give the oxidation states of copper in  $\text{Cu}_2\text{S}$ ,  $\text{Cu}_2\text{O}$ , and Cu.

(b) What are the oxidizing and reducing agents in this reaction?

**22.43** Use equations to show how acid-base properties are used to separate  $\text{Fe}_2\text{O}_3$  and  $\text{TiO}_2$  from  $\text{Al}_2\text{O}_3$  in the Bayer process.

**22.44** A piece of Al with a surface area of  $2.5 \text{ m}^2$  is anodized to produce a film of  $\text{Al}_2\text{O}_3$  that is  $23 \mu\text{m}$  ( $23 \times 10^{-6} \text{ m}$ ) thick. (a) How many coulombs flow through the cell in this process (assume that the density of the  $\text{Al}_2\text{O}_3$  layer is  $3.97 \text{ g/cm}^3$ )? (b) If it takes 18 min to produce this film, what current must flow through the cell?

**22.45** The production of  $\text{H}_2$  gas by the electrolysis of water typically requires about 400 kJ of energy per mole.

(a) Use the relationship between work and cell potential (Section 21.4) to calculate the minimum work needed to form 1.0 mol of  $\text{H}_2$  gas at a cell potential of 1.24 V.

(b) What is the energy efficiency of the cell operation?

(c) Find the cost of producing 500. mol of  $\text{H}_2$  if electricity is \$0.06 per kilowatt-hour (1 watt-second = 1 joule).

**22.46** (a) What are the components of the reaction mixture following the water-gas shift reaction? (b) Explain how zeolites are used to purify the  $\text{H}_2$  formed.

**22.47** Metal sulfides are often first converted to oxides by roasting in air and then reduced with carbon to produce the metal. Why aren't the metal sulfides reduced directly by carbon to yield  $\text{CS}_2$ ? Give a thermodynamic analysis of both processes for ZnS.

## Chemical Manufacturing: Two Case Studies

### Concept Review Questions

**22.48** Explain in detail why a catalyst is used to produce  $\text{SO}_3$ .

**22.49** Among the exothermic steps in the manufacture of sulfuric acid is the process of hydrating  $\text{SO}_3$ . (a) Write two chemical reactions that show this process. (b) Why is the direct reaction of  $\text{SO}_3$  with water not feasible?

**22.50** Why is commercial  $\text{H}_2\text{SO}_4$  so inexpensive?

**22.51** (a) What are the three commercial products formed in the chlor-alkali process?

(b) State an advantage and a disadvantage of using the mercury-cell method for this process.

### Problems in Context

**22.52** Consider the reaction of  $\text{SO}_2$  to form  $\text{SO}_3$  at standard conditions.

(a) Calculate  $\Delta G^\circ$  at  $25^\circ\text{C}$ . Is the reaction spontaneous?

(b) Why is the reaction not performed at  $25^\circ\text{C}$ ?

(c) Is the reaction spontaneous at  $500.^\circ\text{C}$ ? (Assume that  $\Delta H^\circ$  and  $\Delta S^\circ$  are constant with changing  $T$ .)

(d) Compare  $K$  at  $500.^\circ\text{C}$  and at  $25^\circ\text{C}$ .

(e) What is the highest  $T$  at which the reaction is spontaneous?

**22.53** If a chlor-alkali cell used a current of  $3 \times 10^4 \text{ A}$ , how many pounds of  $\text{Cl}_2$  would be produced in a typical 8-h operating day?

**22.54** The products of the chlor-alkali process,  $\text{Cl}_2$  and  $\text{NaOH}$ , are kept separated.

(a) Why is this necessary when  $\text{Cl}_2$  is the desired product?

(b)  $\text{ClO}^-$  or  $\text{ClO}_3^-$  may form by disproportionation of  $\text{Cl}_2$  in basic solution. What determines which product forms?

(c) What mole ratio of  $\text{Cl}_2$  to  $\text{OH}^-$  will produce  $\text{ClO}^-$ ?  $\text{ClO}_3^-$ ?

### Comprehensive Problems

**22.55** The key step in the manufacture of sulfuric acid is the oxidation of sulfur dioxide in the presence of a catalyst, such as  $\text{V}_2\text{O}_5$ . At  $727^\circ\text{C}$ , 0.010 mol of  $\text{SO}_2$  is injected into an empty 2.00-L container ( $K_p = 3.18$ ).

(a) What is the equilibrium pressure of  $\text{O}_2$  that is needed to maintain a 1/1 mole ratio of  $\text{SO}_3$  to  $\text{SO}_2$ ?

(b) What is the equilibrium pressure of  $\text{O}_2$  needed to maintain a 95/5 mole ratio of  $\text{SO}_3$  to  $\text{SO}_2$ ?

**22.56** Tetraphosphorus decoxide ( $\text{P}_4\text{O}_{10}$ ) is made from phosphate rock and used as a drying agent in the laboratory.

(a) Write a balanced equation for its reaction with water.

(b) What is the pH of a solution formed from the addition of 8.5 g of  $\text{P}_4\text{O}_{10}$  to sufficient water to form 0.750 L? (See Table 18.5, for additional information.)

**22.57** Heavy water ( $\text{D}_2\text{O}$ ) is used to make deuterated chemicals.

(a) What major species, aside from the starting compounds, do you expect to find in a solution of  $\text{CH}_3\text{OH}$  and  $\text{D}_2\text{O}$ ?

(b) Write equations to explain how these various species arise. (*Hint*: Consider the autoionization of both components.)

**22.58** A blast furnace uses  $\text{Fe}_2\text{O}_3$  to produce 8400. t of Fe per day.

(a) What mass of  $\text{CO}_2$  is produced each day?

(b) Compare this amount of  $\text{CO}_2$  with that produced by 1.0 million automobiles, each burning 5.0 gal of gasoline a day. Assume that gasoline has the formula  $\text{C}_8\text{H}_{18}$  and a density of 0.74 g/mL, and that it burns completely. (Note that U.S. gasoline consumption is over  $4 \times 10^8$  gal/day.)

**22.59** A major use of  $\text{Cl}_2$  is in the manufacture of vinyl chloride, the monomer of poly(vinyl chloride). The two-step sequence for formation of vinyl chloride is depicted below.

- Write a balanced equation for each step.
- Write the overall equation.
- What type of organic reaction is shown in step 1?
- What type of organic reaction is shown in step 2?
- If each molecule depicted in the initial reaction mixture represents 0.15 mol of substance, what mass (in g) of vinyl chloride forms?

**22.60** In the production of magnesium,  $\text{Mg}(\text{OH})_2$  is precipitated by using  $\text{Ca}(\text{OH})_2$ , which itself is “insoluble.” (a) Use  $K_{\text{sp}}$  values to show that  $\text{Mg}(\text{OH})_2$  can be precipitated from seawater in which  $[\text{Mg}^{2+}]$  is initially 0.052 M. (b) If the seawater is saturated with  $\text{Ca}(\text{OH})_2$ , what fraction of the  $\text{Mg}^{2+}$  is precipitated?

**22.61** Step 1 of the Ostwald process for nitric acid production is

An unwanted side reaction for this step is

- Calculate  $K_{\text{p}}$  for these two  $\text{NH}_3$  oxidations at 25°C.
- Calculate  $K_{\text{p}}$  for these two  $\text{NH}_3$  oxidations at 900°C.
- The Pt/Rh catalyst is one of the most efficient in the chemical industry, achieving 96% yield in 1 millisecond of contact with the reactants. However, at normal operating conditions (5 atm and 850°C), about 175 mg of Pt is lost per metric ton (t) of  $\text{HNO}_3$  produced. If the annual U.S. production of  $\text{HNO}_3$  is  $1.01 \times 10^7$  t and the market price of Pt is \$1557/troy oz, what is the annual cost of the lost Pt (1 kg = 32.15 troy oz)?
- Because of the high price of Pt, a filtering unit composed of ceramic fiber is often installed, which recovers as much as 75% of the lost Pt. What is the value of the Pt captured by a recovery unit with 72% efficiency?

**22.62** Several transition metals are prepared by reduction of the metal halide with magnesium. Titanium is prepared by the Kroll method, in which the ore (ilmenite) is converted to the gaseous chloride, which is then reduced to Ti metal by molten Mg (see the discussion on the isolation of magnesium in Section 22.4). Assuming yields of 84% for step 1 and 93% for step 2, and an excess of the other reactants, what mass of Ti metal can be prepared from 21.5 metric tons of ilmenite?

**22.63** The production of  $\text{S}_8$  from the  $\text{H}_2\text{S}(\text{g})$  found in natural gas deposits occurs through the Claus process (Section 22.5):

(a) Use these two unbalanced steps to write an overall balanced equation for this process:

- Write the overall reaction with  $\text{Cl}_2$  as the oxidizing agent instead of  $\text{O}_2$ . Use thermodynamic data to show whether  $\text{Cl}_2(\text{g})$  can be used to oxidize  $\text{H}_2\text{S}(\text{g})$ .
- Why is oxidation by  $\text{O}_2$  preferred to oxidation by  $\text{Cl}_2$ ?

**22.64** Acid mine drainage (AMD) occurs when geologic deposits containing pyrite ( $\text{FeS}_2$ ) are exposed to oxygen and moisture. AMD is generated in a multistep process catalyzed by acidophilic (acid-loving) bacteria. Balance each step and identify those that increase acidity:

**22.65** Below 912°C, pure iron crystallizes in a body-centered cubic structure (ferrite) with  $d = 7.86 \text{ g/cm}^3$ ; from 912°C to 1394°C, it adopts a face-centered cubic structure (austenite) with  $d = 7.40 \text{ g/cm}^3$ . Both types of iron form interstitial alloys with carbon. The maximum amount of carbon is 0.0218 mass % in ferrite and 2.08 mass % in austenite. Calculate the density of each alloy.

**22.66** Why isn't nitric acid produced by oxidizing  $\text{N}_2$  as follows?

(Hint: Evaluate the thermodynamics of each step.)

**22.67** Before the development of the Downs cell, the Castner cell was used for the industrial production of Na metal. The Castner cell was based on the electrolysis of molten NaOH.

(a) Write balanced cathode and anode half-reactions for this cell.

(b) A major problem with this cell was that the water produced at one electrode diffused to the other and reacted with the Na. If all the water produced reacted with Na, what would be the maximum efficiency of the Castner cell expressed as moles of Na produced per mole of electrons flowing through the cell?

**22.68** When gold ores are leached with  $\text{CN}^-$  solutions, gold forms a complex ion,  $\text{Au}(\text{CN})_2^-$ .

(a) Find  $E_{\text{cell}}$  for the oxidation in air ( $P_{\text{O}_2} = 0.21$ ) of Au to  $\text{Au}^+$  in basic (pH 13.55) solution with  $[\text{Au}^+] = 0.50 \text{ M}$ . Is the reaction  $\text{Au}^+(\text{aq}) + \text{e}^- \longrightarrow \text{Au}(\text{s})$ ,  $E^\circ = 1.68 \text{ V}$ , spontaneous?

(b) How does formation of the complex ion change  $E^\circ$  so that the oxidation can be accomplished?

**22.69** Nitric oxide occurs in the tropospheric nitrogen cycle, but it destroys ozone in the stratosphere.

(a) Write equations for its reaction with ozone and for the reverse reaction.

(b) Given that the forward and reverse steps are first order in each component, write general rate laws for them.

(c) Calculate  $\Delta G^\circ$  for this reaction at 280. K, the average temperature in the stratosphere. (Assume that the  $\Delta H^\circ$  and  $S^\circ$  values in Appendix B do not change with temperature.)

(d) What ratio of rate constants is consistent with  $K$  at this temperature?

**22.70** A key part of the carbon cycle is the fixation of  $\text{CO}_2$  by photosynthesis to produce carbohydrates and oxygen gas.

(a) Using the formula  $(\text{CH}_2\text{O})_n$  to represent a carbohydrate, write a balanced equation for the photosynthetic reaction.

(b) If a tree fixes 48 g of  $\text{CO}_2$  per day, what volume of  $\text{O}_2$  gas measured at 1.0 atm and 78°F does the tree produce per day?

(c) What volume of air (0.040 mol %  $\text{CO}_2$ ) at the same conditions contains this amount of  $\text{CO}_2$ ?

**22.71** Farmers use ammonium sulfate as a fertilizer. In the soil, nitrifying bacteria oxidize  $\text{NH}_4^+$  to  $\text{NO}_3^-$ , a groundwater contaminant that causes methemoglobinemia (“blue baby” syndrome). The World Health Organization standard for maximum  $[\text{NO}_3^-]$  in groundwater is 45 mg/L. A farmer adds 210. kg of  $(\text{NH}_4)_2\text{SO}_4$  to a field and 37% is oxidized to  $\text{NO}_3^-$ . What is the groundwater  $[\text{NO}_3^-]$  (in mg/L) if 1000.  $\text{m}^3$  of the water is contaminated?

**22.72** The key reaction (unbalanced) in the manufacture of synthetic cryolite for aluminum electrolysis is

Assuming a 95.6% yield of dried, crystallized product, what mass (in kg) of cryolite can be obtained from the reaction of 365 kg of  $\text{Al}(\text{OH})_3$ , 1.20  $\text{m}^3$  of 50.0% by mass aqueous  $\text{NaOH}$  ( $d = 1.53 \text{ g/mL}$ ), and 265  $\text{m}^3$  of gaseous  $\text{HF}$  at 305 kPa and 91.5°C? (Assume that the ideal gas law holds.)

**22.73** Because of their different molar masses,  $\text{H}_2$  and  $\text{D}_2$  effuse at different rates (Section 5.5).

(a) If it takes 16.5 min for 0.10 mol of  $\text{H}_2$  to effuse, how long does it take for 0.10 mol of  $\text{D}_2$  to do so in the same apparatus at the same  $T$  and  $P$ ?

(b) How many effusion steps does it take to separate an equimolar mixture of  $\text{D}_2$  and  $\text{H}_2$  to 99 mol % purity?

**22.74** The disproportionation of  $\text{CO}$  to graphite and  $\text{CO}_2$  is thermodynamically favored but slow.

(a) What does this mean in terms of the magnitudes of the equilibrium constant ( $K$ ), rate constant ( $k$ ), and activation energy ( $E_a$ )?

(b) Write a balanced equation for the disproportionation of  $\text{CO}$ .

(c) Calculate  $K_c$  at 298 K.

(d) Calculate  $K_p$  at 298 K.

**22.75** The overall cell reaction for aluminum production is

(a) Assuming 100% efficiency, how many metric tons (t) of  $\text{Al}_2\text{O}_3$  are consumed per metric ton of  $\text{Al}$  produced?

(b) Assuming 100% efficiency, how many metric tons of the graphite anode are consumed per metric ton of  $\text{Al}$  produced?

(c) Actual conditions in an aluminum plant require 1.89 t of  $\text{Al}_2\text{O}_3$  and 0.45 t of graphite per metric ton of  $\text{Al}$ . What is the percent yield of  $\text{Al}$  with respect to  $\text{Al}_2\text{O}_3$ ?

(d) What is the percent yield of  $\text{Al}$  with respect to graphite?

(e) What volume of  $\text{CO}_2$  (in  $\text{m}^3$ ) is produced per metric ton of  $\text{Al}$  at operating conditions of 960.°C and exactly 1 atm?

**22.76** World production of chromite ( $\text{FeCr}_2\text{O}_4$ ), the main ore of chromium, was  $1.97 \times 10^7$  metric tons in 2006. To isolate chromium, a mixture of chromite and sodium carbonate is heated in air to form sodium chromate, iron(III) oxide, and carbon dioxide. The sodium chromate is dissolved in water, and this solution is acidified with sulfuric acid to produce the less soluble sodium dichromate. The sodium dichromate is filtered out and reduced with carbon to produce chromium(III) oxide, sodium carbonate, and carbon monoxide. The chromium(III) oxide is then reduced to chromium with aluminum metal.

(a) Write balanced equations for each step.

(b) What mass of chromium (in kg) could be prepared from the 2006 world production of chromite?

**22.77** Like heavy water ( $\text{D}_2\text{O}$ ), “semi-heavy” water ( $\text{HDO}$ ) undergoes H/D exchange. The molecular scenes depict an initial mixture of  $\text{HDO}$  and  $\text{H}_2$  reaching equilibrium.

(a) Write the balanced equation for the reaction.

(b) Is the value of  $K$  greater or less than 1?

(c) If each molecule depicted represents 0.10  $M$ , calculate  $K$ .

**22.78** Even though most metal sulfides are sparingly soluble in water, their solubilities differ by several orders of magnitude. This difference is sometimes used to separate the metals by controlling the pH. Use the following data to find the pH at which you can separate 0.10  $M$   $\text{Cu}^{2+}$  and 0.10  $M$   $\text{Ni}^{2+}$ :

Saturated  $\text{H}_2\text{S} = 0.10 M$

$K_{a1}$  of  $\text{H}_2\text{S} = 9 \times 10^{-8}$        $K_{a2}$  of  $\text{H}_2\text{S} = 1 \times 10^{-17}$

$K_{sp}$  of  $\text{NiS} = 1.1 \times 10^{-18}$        $K_{sp}$  of  $\text{CuS} = 8 \times 10^{-34}$

**22.79** Ores with as little as 0.25% by mass of copper are used as sources of the metal.

(a) How many kilograms of such an ore would be needed to construct another Statue of Liberty, which contains  $2.0 \times 10^5$  lb of copper?

(b) If the mineral in the ore is chalcopyrite ( $\text{CuFeS}_2$ ), what is the mass % of chalcopyrite in the ore?

**22.80** How does acid rain affect the leaching of phosphate into groundwater from terrestrial phosphate rock? Calculate the solubility of  $\text{Ca}_3(\text{PO}_4)_2$  in each of the following:

(a) Pure water, pH 7.0 (Assume that  $\text{PO}_4^{3-}$  does not react with water.)

(b) Moderately acidic rainwater, pH 4.5 (*Hint*: Assume that all the phosphate exists in the form that predominates at this pH.)

**22.81** The lead(IV) oxide used in car batteries is prepared by coating an electrode plate with  $\text{PbO}$  and then oxidizing it to lead dioxide ( $\text{PbO}_2$ ). Despite its name,  $\text{PbO}_2$  has a nonstoichiometric mole ratio of lead to oxygen of about 1/1.98. In fact, the holes in the  $\text{PbO}_2$  crystal structure due to missing O atoms are responsible for the oxide’s conductivity.

(a) What is the mole % of O missing from the  $\text{PbO}_2$  structure?

(b) What is the molar mass of the nonstoichiometric compound?

**22.82** Chemosynthetic bacteria reduce  $\text{CO}_2$  by “splitting”  $\text{H}_2\text{S}(g)$  instead of the  $\text{H}_2\text{O}(g)$  used by photosynthetic organisms. Compare the free energy change for splitting  $\text{H}_2\text{S}$  with that for splitting  $\text{H}_2\text{O}$ . Is there an advantage to using  $\text{H}_2\text{S}$  instead of  $\text{H}_2\text{O}$ ?

**22.83** Silver has a face-centered cubic structure with a unit cell edge length of 408.6 pm. Sterling silver is a substitutional alloy that contains 7.5% copper atoms. Assuming the unit cell remains the same, find the density of silver and of sterling silver.

**22.84** Earth's mass is estimated to be  $5.98 \times 10^{24}$  kg, and titanium represents 0.05% by mass of this total.

- (a) How many moles of Ti are present?  
 (b) If half of the Ti is found as ilmenite ( $\text{FeTiO}_3$ ), what mass of ilmenite is present?  
 (c) If the airline and auto industries use  $1.00 \times 10^5$  tons of Ti per year, how many years will it take to use up all the Ti (1 ton = 2000 lb)?

**22.85** In 1790, Nicolas Leblanc found a way to form  $\text{Na}_2\text{CO}_3$  from NaCl. His process, now obsolete, consisted of three steps:

- (a) Write a balanced overall equation for the process.  
 (b) Calculate the  $\Delta H_f^\circ$  of CaS if  $\Delta H_{\text{rxn}}^\circ$  is 351.8 kJ/mol.

(c) Is the overall process spontaneous at standard-state conditions and 298 K?

(d) How many grams of  $\text{Na}_2\text{CO}_3$  form from 250. g of NaCl if the process is 73% efficient?

**22.86** Limestone ( $\text{CaCO}_3$ ) is the second most abundant mineral on Earth after  $\text{SiO}_2$ . For many uses, it is first decomposed thermally to quicklime ( $\text{CaO}$ ). MgO is prepared similarly from  $\text{MgCO}_3$ .

(a) At what  $T$  is each decomposition spontaneous?

(b) Quicklime reacts with  $\text{SiO}_2$  to form a slag ( $\text{CaSiO}_3$ ), a by-product of steelmaking. In 2010, the total steelmaking capacity of the U.S. steel industry was 2,236,000 tons per week, but only 84% of this capacity was utilized. If 50. kg of slag is produced per ton of steel, what mass (in kg) of limestone was used to make slag in 2010?

## Concepts and Skills to Review Before You Study This Chapter

- › properties of light (Section 7.1)
- › electron shielding of nuclear charge (Section 8.1)
- › electron configuration, ionic size, and magnetic behavior (Sections 8.2 to 8.4)
- › valence bond theory (Section 11.1)
- › constitutional, geometric, and optical isomerism (Section 15.2)
- › Lewis acid-base concepts (Section 18.9)
- › complex-ion formation (Section 19.4)
- › redox behavior and standard electrode potentials (Section 21.3)

Though almost at the end of the text, we still haven't discussed the majority of the elements *and* some of the most familiar. The **transition elements** (*transition metals*) make up the *d* block (B groups) and *f* block (*inner transition elements*) of the periodic table (Figure 23.1, *next page*) and have crucial uses in industry and biology.

Aside from essential copper and iron (Chapter 22), some other indispensable transition elements are chromium (plumbing fixtures), gold and silver (jewelry and electronics), platinum (automobile catalytic converters), titanium (bicycle and aircraft parts and artificial joints), nickel (coins and catalysts), and zinc (batteries), to mention a few of the better known ones. There are also the lesser known zirconium (nuclear-reactor liners), vanadium (axles and crankshafts), molybdenum (boiler plates), tantalum (organ-replacement parts), palladium (telephone-relay contacts)—the list goes on and on.

Transition metal cations occupy the centers of many complex ions. In addition to providing fundamental insights into bonding and structure, these species play vital roles in organisms and give color to gems—Cr<sup>3+</sup> ions make emeralds green and rubies red, and a mixture of Fe<sup>2+</sup>, Fe<sup>3+</sup>, and Ti<sup>4+</sup> ions makes sapphires blue (*see photo*).

**IN THIS CHAPTER . . .** We focus on the transition elements and their properties, and especially on the bonding and structure of their coordination compounds.

- › We discuss key atomic, physical, and chemical properties of transition and inner transition elements—with attention to the effects of filling inner sublevels—and contrast them with properties of the main-group elements.
- › For most of the chapter, we concentrate on the nomenclature, structure, and isomerism of transition elements' coordination compounds, species that contain complex ions.
- › We use valence bond theory to explain the bonding and molecular shape of complex ions.
- › We use crystal field theory to explain the colors and magnetic properties of coordination compounds, which relate directly to structure.
- › We end with some examples of the roles of transition metal ions in biochemistry.

### 23.1 PROPERTIES OF THE TRANSITION ELEMENTS

The transition elements differ considerably in physical and chemical behavior from the main-group elements:

- *All transition elements are metals*, whereas the main-group elements in each period change from metal to nonmetal.
- *Many transition metal compounds are colored and paramagnetic*, whereas most main-group ionic compounds are colorless and diamagnetic.

**Figure 23.1** The transition elements (*d* block) and inner transition elements (*f* block) in the periodic table.

	1A (1)																		8A (18)

58 Ce	59 Pr	60 Nd	61 Pm	62 Sm	63 Eu	64 Gd	65 Tb	66 Dy	67 Ho	68 Er	69 Tm	70 Yb	71 Lu
90 Th	91 Pa	92 U	93 Np	94 Pu	95 Am	96 Cm	97 Bk	98 Cf	99 Es	100 Fm	101 Md	102 No	103 Lr

We first discuss electron configurations of the atoms and ions of transition elements and then examine these elements' key properties to see how they contrast with the same properties of main-group elements.

## Electron Configurations of the Transition Metals and Their Ions

As with all the elements, the properties of the transition elements and their compounds arise largely from the electron configurations of their atoms (Section 8.2) and ions (Section 8.4). As Figure 23.1 shows, *d*-block (B-group) elements occur in four series that lie within Periods 4 through 7 between the last *ns*-block element [Group 2A(2)] and the first *np*-block element [Group 3A(13)]. Each of the four series contains ten elements based on the filling of five *d* orbitals, for a total of 40 transition elements. Lying between the first and second members of the series in Periods 6 and 7 are the inner transition elements, in which *f* orbitals are filled. Several points are important to review:

1. *Electron configurations of the atoms.* Despite several exceptions, in general, the condensed ground-state electron configuration for the atoms in each *d*-block series is

$$[\text{noble gas}] ns^2(n-1)d^x, \text{ with } n = 4 \text{ to } 7 \text{ and } x = 1 \text{ to } 10$$

In Periods 6 and 7, the condensed configuration includes the *f* sublevel:

$$[\text{noble gas}] ns^2(n-2)f^{14}(n-1)d^x, \text{ with } n = 6 \text{ or } 7$$

The *partial* (valence-level) electron configuration for the *d*-block elements excludes the noble gas core and the filled inner *f* sublevel:

$$ns^2(n-1)d^x$$

**Figure 23.2** The Period 4 transition metals. The ten elements appear in periodic-table order across pages 1038–1039.

2. *Filling pattern in Period 4.* The first (Period 4) transition series consists of scandium (Sc) through zinc (Zn) (Figure 23.2 and Table 23.1). Scandium has the electron configuration  $[\text{Ar}] 4s^2 3d^1$ , and the addition of one electron at a time first half-fills, then fills, the 3d orbitals, up to zinc. Recall that chromium and copper are exceptions to this pattern:

- The 4s and 3d orbitals in Cr are half-filled to give  $[\text{Ar}] 4s^1 3d^5$ .
- The 4s orbital in Cu is half-filled to give  $[\text{Ar}] 4s^1 3d^{10}$ .

These exceptions are due to the relative energies of the 4s and 3d sublevels as electrons are added and to the unusual stability of half-filled and filled sublevels (see Figure 8.26).

3. *Electron configurations of the ions.* Transition metal ions form through the loss of ns electrons before (n - 1)d electrons. Thus, Ti loses the two 4s electrons to form the  $\text{Ti}^{2+}$  ion:

$\text{Ti}^{2+}$  is referred to as a  $d^2$  ion. Ions of different metals with the same configuration often have similar properties. For example,  $\text{Mn}^{2+}$  and  $\text{Fe}^{3+}$  are  $d^5$  ions:

Both have pale colors in solution and form complex ions with similar magnetic properties.

Table 23.1 shows partial orbital box diagrams for the Period 4 elements. In general for all periods of the transition elements, the number of unpaired electrons (or half-filled orbitals) increases in the first half of the series and, when pairing begins, decreases in the second half. A key point to note in upcoming discussions is that the electron configuration of the atom (O.N. = 0) correlates with the physical properties

Iron, Fe; 8B(8)

Cobalt, Co; 8B(9)

Nickel, Ni; 8B(10)

Copper, Cu; 1B(11)

Zinc, Zn; 2B(12)

of the *element*, whereas the electron configuration of the *ion* (and other species of higher O.N.) correlates with the chemical properties of the *compounds*.

### SAMPLE PROBLEM 23.1

### Writing Electron Configurations of Transition Metal Atoms and Ions

**Problem** Write *condensed* electron configurations for the following: (a) Zr; (b)  $V^{3+}$ ; (c)  $Mo^{3+}$ . (Assume that transition elements in higher periods behave like those in Period 4.)

**Plan** We locate the element in the periodic table and count its position in the respective transition series. These elements are in Periods 4 and 5, so the general configuration is [noble gas]  $ns^2(n-1)d^x$ . For the ions, we recall that  $ns$  electrons are lost first.

**Solution** (a) Zr is the second element in the 4d series: [Kr]  $5s^24d^2$ .

(b) V is the third element in the 3d series: [Ar]  $4s^23d^3$ . In forming  $V^{3+}$ , three electrons are lost (two 4s and one 3d), so  $V^{3+}$  is a  $d^2$  ion: [Ar]  $3d^2$ .

(c) Mo lies below Cr in Group 6B(6), so we expect the same exception as for Cr. Thus, Mo has the electron configuration [Kr]  $5s^14d^5$ . To form the ion, Mo loses the one 5s and two of the 4d electrons, so  $Mo^{3+}$  is a  $d^3$  ion: [Kr]  $4d^3$ .

**Check** Figure 8.9 shows we're correct for the atoms. Be sure that charge plus number of  $d$  electrons in the ion equals the sum of outer  $s$  and  $d$  electrons in the atom.

### FOLLOW-UP PROBLEMS

*Brief Solutions for all Follow-up Problems appear at the end of the chapter.*

**23.1A** Write *partial* electron configurations (no noble gas core or filled inner sublevels) for the following: (a)  $Ag^+$ ; (b)  $Cd^{2+}$ ; (c)  $Ir^{3+}$ .

**23.1B** Find the charge of each of the following ions, given the *condensed* electron configuration: (a)  $Ta^{x+}$ : [Xe]  $4f^{14}5d^2$ ; (b)  $Mn^{x+}$ : [Ar]  $3d^3$ ; (c)  $Os^{x+}$ : [Xe]  $4f^{14}5d^5$ .

**SOME SIMILAR PROBLEMS** 23.10–23.15

## Atomic and Physical Properties of the Transition Elements

Properties of the transition elements contrast in several ways with properties of the main-group elements.

**Trends Across a Period** Consider the variations in atomic size, electronegativity, and ionization energy across Period 4 (Figure 23.3):

**A** Atomic radius (pm)

- Atomic size.** Atomic size decreases overall across the period (Figure 23.3A). There is a smooth, steady decrease across the main groups because the electrons are added to *outer ns* or *np* orbitals, which shield the increasing nuclear charge poorly.

This decrease is not steady in the transition series, where *atomic size decreases at first but then remains relatively constant*. The reason is that the  $d$  electrons fill *inner* orbitals, so they shield outer electrons very efficiently; therefore, the outer 4s electrons are *not* pulled closer.

**B** Electronegativity

- Electronegativity (EN).** Electronegativity generally increases across the period, but, once again, the main groups show a steady, steep increase between the metal potassium (0.8) and the nonmetal bromine (2.8), whereas the transition elements

have *relatively constant EN* (Figure 23.3B), consistent with their relatively constant size. The transition elements all have intermediate electronegativity values, much like the large, metallic members of Groups 3A(13) to 5A(15).

**C** First ionization energy (kJ/mol)

- Ionization energy ( $IE_1$ ).** The ionization energies of the Period 4 main-group elements rise steeply from left to right, more than tripling from potassium (419 kJ/mol) to krypton (1351 kJ/mol), as electrons become more difficult to remove from the poorly shielded, increasing nuclear charge. In the transition metals,  $IE_1$  values *increase relatively little* because the inner 3d electrons shield more effectively (Figure 23.3C). [Recall from Section 8.3 that the drop at Group 3A(13) occurs because it is relatively easy to remove the first electron from the outer  $np$  orbital.]

**Figure 23.3** Trends in key atomic properties of Period 4 elements. Relative sizes of atomic radius (**A**), electronegativity (**B**), and first ionization energy (**C**) for all Period 4 elements are indicated by the heights of the bars, with darker shading on the transition series.

**Trends Within a Group** Vertical trends for transition elements are also different from main-group trends.

1. *Atomic size.* As expected, atomic size increases from Period 4 to 5, as it does for the main-group elements, but there is virtually *no size increase from Period 5 to 6* (Figure 23.4A). Since the lanthanides, with their buried  $4f$  sub-level, appear between the  $4d$  (Period 5) and  $5d$  (Period 6) series, an element in Period 6 is separated from the one above it by 32 elements (ten  $4d$ , six  $5p$ , two  $6s$ , and fourteen  $4f$  electrons) instead of just 18. The fourteen  $4f$  electrons shield the outer electrons poorly from the increase in nuclear charge due to fourteen additional protons, resulting in a shrinkage in atomic size called the **lanthanide contraction**. By coincidence, this size *decrease* is about equal to the normal *increase* between periods, so Periods 5 and 6 transition elements have about the same atomic sizes.

2. *Electronegativity.* The vertical trend in electronegativity is opposite the decreasing trend in the main groups. Electronegativity *increases* from Period 4 to Period 5, but there is no further increase in Period 6 (Figure 23.4B). The heavier elements, especially gold (EN = 2.4), become quite electronegative, with values higher than most metalloids and even some nonmetals (e.g., EN of Te and of P = 2.1). (In fact, with the very electropositive cesium, which has EN = 0.7, gold forms the saltlike CsAu.) Although atomic size increases slightly from top to bottom in a group, the nuclear charge increases much more. Therefore, the heavier transition metals form bonds with more covalent character because they attract electrons more strongly than do main-group metals.

3. *Ionization energy.* The small increase in size combined with the large increase in nuclear charge also explains why  $IE_1$  values *generally increase* down a transition group (Figure 23.4C). This trend also runs counter to the main-group trend, where heavier members are so much larger that the outer electron is easier to remove.

4. *Density.* Atomic size, and therefore volume, is inversely related to density. Across a period, densities increase, then level off, and finally dip a bit at the end of

**Figure 23.4** Vertical trends in key properties within the transition elements. The trends are unlike those for the main-group elements.

a series (Figure 23.4D). Down a transition group, densities increase dramatically because atomic volumes change little from Period 5 to 6, but atomic masses increase significantly. As a result, the Period 6 series contains some of the densest elements known: tungsten, rhenium, osmium, iridium, platinum, and gold have densities about 20 times that of water and twice that of lead.

## Chemical Properties of the Transition Elements

Like their atomic and physical properties, the chemical properties of transition elements are very different from those of main-group elements. Let's examine key properties in the Period 4 series and then see how behavior changes within a group.

**Multiple Oxidation States** One of the most characteristic chemical properties of the transition metals is the occurrence of *multiple oxidation states*; main-group metals display one or, at most, two states. For example, chromium and manganese (Figure 23.5A) have three common oxidation states and many others that are less common (Table 23.2). Since the  $ns$  and  $(n - 1)d$  electrons are so close in energy, transition elements can use all or most of these electrons in bonding.

Oxidation States and $d$ -Orbital Occupancy of the Period 4 Transition Metals*										
Table 23.2	3B	4B	5B	6B	7B	8B	8B	8B	1B	2B
	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)
	Sc	Ti	V	Cr	Mn	Fe	Co	Ni	Cu	Zn
0	$d^1$	$d^2$	$d^3$	$d^5$	$d^5$	$d^6$	$d^7$	$d^8$	$d^{10}$	$d^{10}$
+1			$d^3$	$d^5$	$d^5$	$d^6$	$d^7$	$d^8$	$d^{10}$	
+2		$d^2$	$d^3$	$d^4$	$d^5$	$d^6$	$d^7$	$d^8$	$d^9$	$d^{10}$
+3	$d^0$	$d^1$	$d^2$	$d^3$	$d^4$	$d^5$	$d^6$	$d^7$	$d^8$	
+4		$d^0$	$d^1$	$d^2$	$d^3$	$d^4$	$d^5$	$d^6$		
+5			$d^0$	$d^1$	$d^2$		$d^4$			
+6				$d^0$	$d^1$	$d^4$				
+7					$d^0$					

\*The most important orbital occupancies are in color.

The highest oxidation state of elements in Groups 3B(3) through 7B(7) equals the group number. These states are seen when the elements combine with highly electronegative oxygen or fluorine. For instance, Figure 23.5B shows vanadium as vanadate ion ( $\text{VO}_4^{3-}$ ; O.N. of V = +5), chromium as dichromate ( $\text{Cr}_2\text{O}_7^{2-}$ ; O.N. of Cr = +6), and manganese as permanganate ( $\text{MnO}_4^-$ ; O.N. of Mn = +7).

Elements in Groups 8B(8), 8B(9), and 8B(10) exhibit fewer oxidation states, and the highest state is less common and never equal to the group number. For example, we never encounter iron in the +8 state and only rarely in the +6 state. The +2 and +3 states are the most common ones for iron\* and cobalt, and the +2 state is most common for nickel, copper, and zinc. The +2 oxidation state is common because  $ns^2$  electrons are readily lost.

**Metallic Behavior, Oxide Acidity, and Valence-State Electronegativity** Atomic size and oxidation state have a major effect on the nature of bonding in transition metal compounds. Like the metals in Groups 3A(13), 4A(14), and 5A(15), the

\*Iron seems to have unusual oxidation states in magnetite ( $\text{Fe}_3\text{O}_4$ ) and pyrite ( $\text{FeS}_2$ ), but it doesn't. In magnetite, one-third of the metal ions are  $\text{Fe}^{2+}$  and two-thirds are  $\text{Fe}^{3+}$ , which gives a 1/1 ratio of  $\text{FeO}/\text{Fe}_2\text{O}_3$  and a formula of  $\text{Fe}_3\text{O}_4$ . Pyrite contains  $\text{Fe}^{2+}$  combined with the disulfide ion,  $\text{S}_2^{2-}$ .

transition elements in their *lower* oxidation states behave chemically more like metals. That is, *ionic bonding is more prevalent for the lower oxidation states, and covalent bonding is more prevalent for the higher states*. For example, at room temperature,  $\text{TiCl}_2$  (O.N. = +2) is an ionic solid, whereas  $\text{TiCl}_4$  (O.N. = +4) is a molecular liquid (see also Figure 14.11). In the higher oxidation states, the atoms have higher charge densities (higher ratio of charge to volume, Section 13.3), so they polarize the electron clouds of the nonmetal ions more strongly and the bonding becomes more covalent. For the same reason, the oxides become less basic (more acidic) as the oxidation state increases:  $\text{TiO}$  is weakly basic in water, whereas  $\text{TiO}_2$  is amphoteric (reacts with both acid and base).

Why does oxide acidity increase with oxidation state? And, how can a metal like chromium or manganese, in addition to forming oxides, form an oxoanion in which it uses covalent bonds? The answers involve a type of “effective” electronegativity called *valence-state electronegativity*, which also has numerical values. A metal atom with a positive oxidation state has a greater attraction for the bonded electrons, that is, a higher electronegativity, than it does when it has a zero oxidation state. Thus, for example, the electronegativity of elemental chromium is 1.6, close to that of aluminum (1.5), another active metal. For chromium(III), the value increases to 1.7, still characteristic of a metal. But, for chromium(VI), the value is 2.3, close to the values of some nonmetals, such as phosphorus (2.1) and sulfur (2.5). Thus, like P in  $\text{PO}_4^{3-}$  and S in  $\text{SO}_4^{2-}$ , Cr in  $\text{CrO}_4^{2-}$  is covalently bonded at the center of an oxoanion of a relatively strong acid,  $\text{H}_2\text{CrO}_4$ , and manganese(VII) in  $\text{MnO}_4^-$  behaves similarly in the strong acid  $\text{HMnO}_4$ .

**Reducing Strength** Table 23.3 shows the standard electrode potentials of the Period 4 transition metals in their +2 oxidation state in acid solution. Note that, in general, reducing strength decreases across the series. All the Period 4 transition metals, except copper, are active enough to reduce  $\text{H}^+$  from aqueous acid to form hydrogen gas. In contrast to the rapid reaction at room temperature of the Group 1A(1) and 2A(2) metals with water, however, most transition metals have an oxide coating that allows rapid reaction only with hot water or steam.

**Color and Magnetism of Compounds** *Most main-group ionic compounds are colorless* because the metal ion has a filled outer level (noble gas electron configuration,  $ns^2$  or  $ns^2np^6$ ). With only *much* higher energy orbitals available to receive an excited electron, the ion does not absorb visible light. In contrast, electrons in a partially filled  $d$  sublevel can absorb visible wavelengths and move to *slightly* higher energy orbitals. As a result, *many transition metal compounds have striking colors*. Exceptions are the compounds of scandium, titanium(IV), and zinc, which are colorless because their metal ions have either an empty  $d$  sublevel ( $\text{Sc}^{3+}$  or  $\text{Ti}^{4+}$ :  $[\text{Ar}] 3d^0$ ) or a filled one ( $\text{Zn}^{2+}$ :  $[\text{Ar}] 3d^{10}$ ) (Figure 23.6).

**Standard Electrode Potentials of  $\text{M}^{2+}$  Ions of Period 4 Transition Metals**

**Table 23.3**

Half-Reaction	$E^\circ$ (V)
$\text{Ti}^{2+}(\text{aq}) + 2\text{e}^- \rightleftharpoons \text{Ti}(\text{s})$	-1.63
$\text{V}^{2+}(\text{aq}) + 2\text{e}^- \rightleftharpoons \text{V}(\text{s})$	-1.19
$\text{Cr}^{2+}(\text{aq}) + 2\text{e}^- \rightleftharpoons \text{Cr}(\text{s})$	-0.91
$\text{Mn}^{2+}(\text{aq}) + 2\text{e}^- \rightleftharpoons \text{Mn}(\text{s})$	-1.18
$\text{Fe}^{2+}(\text{aq}) + 2\text{e}^- \rightleftharpoons \text{Fe}(\text{s})$	-0.44

Table 23.4

Some Properties of Group 6B(6) Elements

Element	Atomic Radius (pm)	IE <sub>1</sub> (kJ/mol)	E° (V) for M <sup>3+</sup> (aq)   M(s)
Cr	128	653	-0.74
Mo	139	685	-0.20
W	139	770	-0.11

Magnetic properties are also related to sublevel occupancy (Section 8.4). *Most main-group metal ions are diamagnetic* for the same reason they are colorless: all their electrons are paired. In contrast, *many transition metal compounds are paramagnetic because of their unpaired d electrons*. Transition metal ions with a  $d^0$  or  $d^{10}$  configuration are also colorless and diamagnetic.

**Chemical Behavior Within a Group** The *increase* in reactivity going down a group of main-group metals due to the *decrease* in IE<sub>1</sub> does *not* occur going down a group of transition metals. The chromium (Cr) group [6B(6)] shows a typical pattern (Table 23.4). IE<sub>1</sub> *increases* down the group, which makes the two heavier members *less* reactive than the lightest one. Chromium is also a much stronger reducing agent than molybdenum (Mo) or tungsten (W), as shown by the standard electrode potentials.

The similarity in atomic size of members of Periods 5 and 6 leads to similar chemical behavior, which has some important consequences. Because Mo and W compounds behave similarly, their ores often occur together in nature, which makes these elements very difficult to separate. The same situation occurs with zirconium and hafnium in Group 4B(4) and with niobium and tantalum in Group 5B(5).

### › Summary of Section 23.1

- › All transition elements are metals.
- › Atoms of the *d*-block elements have  $(n - 1)d$  orbitals being filled, and their ions have an empty *ns* orbital.
- › Unlike the trends for the main-group elements, the atomic size, electronegativity, and first ionization energy change relatively little across a transition series. Because of the lanthanide contraction, atomic size changes little from Period 5 to 6 in a transition metal group; thus, electronegativity, first ionization energy, and density *increase* down such a group.
- › Transition metals typically have several oxidation states, with the +2 state most common. The elements exhibit less metallic behavior in their higher states, as they have higher valence-state electronegativity.
- › Most Period 4 transition metals are active enough to reduce hydrogen ion from acid solution.
- › Many transition metal compounds are colored and paramagnetic because the metal ion has unpaired *d* electrons.
- › In contrast to main-group metals, transition metals show decreasing reactivity down a group.

## 23.2 THE INNER TRANSITION ELEMENTS

The 14 **lanthanides** in Period 6 [cerium (Ce;  $Z = 58$ ) through lutetium (Lu;  $Z = 71$ )] and the 14 **actinides** in Period 7 [thorium (Th;  $Z = 90$ ) through lawrencium (Lr;  $Z = 103$ )] are called **inner transition elements** because their seven inner *4f* or *5f* orbitals are being filled.

### The Lanthanides

The lanthanides are also known as the *rare earth elements*, but many are not rare: cerium (Ce), for instance, ranks 26<sup>th</sup> in abundance (by mass %) and is five times more abundant than lead. All the lanthanides are silvery, high-melting metals.

As with other transition elements, atomic properties vary little across the period. As a result, chemical properties are so similar that the two ores of lanthanides, ceria and yttria, are mixtures of compounds of all 14 of them. This natural co-occurrence arises because the elements exist as  $M^{3+}$  ions of very similar radii. Most lanthanides have the ground-state electron configuration  $[\text{Xe}] 6s^2 4f^x 5d^0$ , where  $x$  varies across the series. The three exceptions (Ce, Gd, and Lu) have a single electron in one of their  $5d$  orbitals: cerium ( $[\text{Xe}] 6s^2 4f^1 5d^1$ ) forms a stable  $4+$  ion with an empty ( $f^0$ ) sublevel, and the  $\text{Gd}^{3+}$  and  $\text{Lu}^{3+}$  ions have a stable half-filled ( $f^7$ ) or filled ( $f^{14}$ ) sublevel.

Lanthanide compounds are used in tinted glass, electronic devices (magnets, batteries, and lasers), and high-quality camera lenses, but two industrial applications account for over 60% of the total usage. In gasoline refining, catalysts used to “crack” hydrocarbons into smaller molecules are 5% by mass rare earth oxides. In steelmaking, a mixture of lanthanides, called *misch metal*, removes carbon impurities from molten iron and steel. Recently, shortages of some lanthanides used for certain electronic applications have been a concern.

### SAMPLE PROBLEM 23.2

### Finding the Number of Unpaired Electrons

**Problem** The alloy  $\text{SmCo}_5$  forms a permanent magnet because both samarium and cobalt have unpaired electrons. How many unpaired electrons are in Sm ( $Z = 62$ )?

**Plan** We write the condensed electron configuration of Sm and then, using Hund’s rule and the aufbau principle, place the electrons in a partial orbital diagram and count the unpaired electrons.

**Solution** Samarium is the eighth element after Xe. Two electrons go into the  $6s$  sublevel. In general, the  $4f$  sublevel fills before the  $5d$  (among the lanthanides, only Ce, Gd, and Lu have  $5d$  electrons), so the remaining electrons go into the  $4f$ . Thus, the condensed configuration of Sm is  $[\text{Xe}] 6s^2 4f^6$ . There are seven  $f$  orbitals, so each of the six  $f$  electrons enters a separate orbital:

Thus, Sm has **six unpaired electrons**.

**Check** Six  $4f$   $e^-$  plus two  $6s$   $e^-$  plus the 54  $e^-$  in Xe gives 62, the atomic number of Sm.

### FOLLOW-UP PROBLEMS

**23.2A** How many unpaired electrons are in the  $\text{Er}^{3+}$  ion?

**23.2B** How many unpaired electrons are in the  $\text{Dy}^{3+}$  ion?

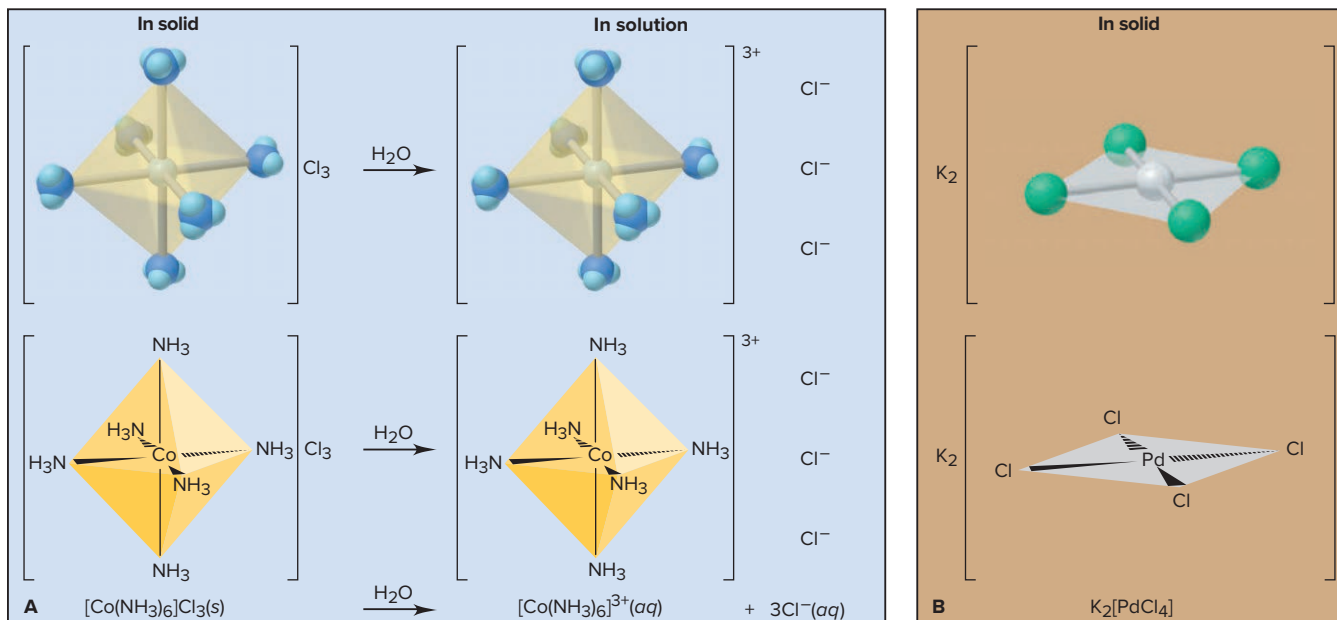

**SOME SIMILAR PROBLEMS** 23.30–23.34

## The Actinides

All actinides are radioactive. Like the lanthanides, they have very similar physical and chemical properties. Thorium and uranium occur in nature, but the transuranium elements, those with  $Z$  greater than 92, have been synthesized in particle accelerators (as we discuss in Section 24.3). The actinides are silvery and chemically reactive and, like the lanthanides, form highly colored compounds. The actinides and lanthanides have similar outer-electron configurations. Although the  $+3$  oxidation state is characteristic of the actinides, as it is for the lanthanides, other states also occur. For example, uranium exhibits  $+3$  through  $+6$  states, with the  $+6$  state the most prevalent; thus, the most common oxide of uranium is  $\text{UO}_3$ .

### › Summary of Section 23.2

- › There are two series of inner transition elements. The lanthanides ( $4f$  series) have a common  $+3$  oxidation state and exhibit very similar properties.
- › The actinides ( $5f$  series) are radioactive. All actinides have a  $+3$  oxidation state; several, including uranium, have higher states as well.

**Figure 23.7** Components of a coordination compound. Coordination compounds are shown as models (top), wedge-bond perspective drawings (middle), and formulas (bottom). **A**, When  $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$  dissolves in water, the six ligands remain bound in the complex ion. **B**,  $\text{K}_2[\text{PdCl}_4]$  has four  $\text{Cl}^-$  ligands and two  $\text{K}^+$  counter ions.

The complex ion  $[\text{Cr}(\text{NH}_3)_6]^{3+}$  has a central  $\text{Cr}^{3+}$  ion bonded to six  $\text{NH}_3$  ligands.

## 23.3 COORDINATION COMPOUNDS

The most distinctive feature of transition metal chemistry is the common occurrence of **coordination compounds** (or *complexes*). These species contain at least one **complex ion**, which consists of a *central metal cation bonded to molecules and/or anions called ligands* (see margin). To maintain charge neutrality, the complex ion is associated with **counter ions**. In the coordination compound  $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$  (Figure 23.7A), the complex ion (in square brackets) is  $[\text{Co}(\text{NH}_3)_6]^{3+}$ , the six  $\text{NH}_3$  molecules bonded to the  $\text{Co}^{3+}$  are ligands, and the three  $\text{Cl}^-$  ions are counter ions. The coordination compound  $\text{K}_2[\text{PdCl}_4]$  in Figure 23.7B consists of two  $\text{K}^+$  counter ions and the complex ion  $[\text{PdCl}_4]^{2-}$ , in which  $\text{Pd}^{2+}$  is bonded to four  $\text{Cl}^-$  ion ligands.

*A coordination compound behaves like an electrolyte in water:* the complex ion and counter ions separate, but the complex ion behaves like a polyatomic ion because *the ligands and central metal ion remain attached*. Thus, as Figure 23.7 shows, 1 mol of  $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$  yields 1 mol of  $[\text{Co}(\text{NH}_3)_6]^{3+}$  ions and 3 mol of  $\text{Cl}^-$  counter ions while 1 mol of  $\text{K}_2[\text{PdCl}_4]$  yields 2 mol of  $\text{K}^+$  counter ions and 1 mol of  $[\text{PdCl}_4]^{2-}$  ions. This section covers the structure, naming, and properties of complex ions.

### Complex Ions: Coordination Numbers, Geometries, and Ligands

A complex ion is described by the metal ion and the number and types of ligands attached to it. The ion's structure is related to coordination number and geometry.

**Coordination Numbers** The **coordination number** is the *number of ligand atoms* bonded directly to the central metal ion in a complex ion. It is *specific* for a given metal ion in a particular oxidation state and in a particular complex ion. The coordination number of the  $\text{Co}^{3+}$  ion in  $[\text{Co}(\text{NH}_3)_6]^{3+}$  is 6 because six ligand atoms (N atoms of  $\text{NH}_3$  molecules) are bonded to it. The coordination number of the  $\text{Pt}^{2+}$  ion in many of its complex ions is 4, whereas that of the  $\text{Pt}^{4+}$  ion in its complex ions is 6. Copper(II) may have a coordination number of 2, 4, or 6 in different complex ions. In general, *the most common coordination number in complex ions is 6*, but 2 and 4 are often seen, and some higher ones are known.

#### Student Hot Spot

Student data indicate that you may struggle with the concept of coordination compounds and their features. Access the Smartbook to view additional Learning Resources on this topic.

Table 23.5

Coordination Numbers and Shapes of Some Complex Ions

Coordination Number	Shape		Examples
2	Linear		$[\text{CuCl}_2]^-$ , $[\text{Ag}(\text{NH}_3)_2]^+$ , $[\text{AuCl}_2]^-$
4	Square planar		$[\text{Ni}(\text{CN})_4]^{2-}$ , $[\text{PdCl}_4]^{2-}$ , $[\text{Pt}(\text{NH}_3)_4]^{2+}$ , $[\text{Cu}(\text{NH}_3)_4]^{2+}$
4	Tetrahedral		$[\text{Cu}(\text{CN})_4]^{3-}$ , $[\text{Zn}(\text{NH}_3)_4]^{2+}$ , $[\text{CdCl}_4]^{2-}$ , $[\text{MnCl}_4]^{2-}$
6	Octahedral		$[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ , $[\text{V}(\text{CN})_6]^{4-}$ , $[\text{Cr}(\text{NH}_3)_4\text{Cl}_2]^+$ , $[\text{Mn}(\text{H}_2\text{O})_6]^{2+}$ , $[\text{FeCl}_6]^{3-}$ , $[\text{Co}(\text{en})_3]^{3+}$

**Geometries** The geometry (shape) of a complex ion depends on the *coordination number and the metal ion*. Table 23.5 shows the geometries for coordination numbers 2, 4, and 6. A complex ion whose metal ion has a coordination number of 2, such as  $[\text{Ag}(\text{NH}_3)_2]^+$ , is *linear*. The coordination number 4 gives rise to either of two geometries. Most  $d^8$  metal ions form *square planar* complex ions (Figure 23.7B). The  $d^{10}$  ions form *tetrahedral* complex ions. A coordination number of 6 results in an *octahedral* geometry, as shown by  $[\text{Co}(\text{NH}_3)_6]^{3+}$  (Figure 23.7A). Note the similarity with some of the molecular shapes in VSEPR theory (Section 10.2).

**Ligands** The ligands of complex ions are *molecules or anions* with one or more **donor atoms**. Each *donates a lone pair of electrons* to the metal ion, thus forming a covalent bond. Because they must have at least one lone pair, donor atoms often come from Group 5A(15), 6A(16), or 7A(17). (As you learned in Section 18.9, ligands are Lewis bases.)

Ligands are classified in terms of their number of donor atoms, or “teeth”:

- *Monodentate* (Latin, “one-toothed”) ligands bond through a single donor atom.
- *Bidentate* ligands have two donor atoms, each of which bonds to the metal ion.
- *Polydentate* ligands have more than two donor atoms.

Bidentate and polydentate ligands give rise to *rings* in the complex ion. For instance, ethylenediamine (abbreviated *en*) has a chain of four atoms ( $:\text{N}-\text{C}-\text{C}-\text{N}:$ ), so it forms a five-membered ring, with the two electron-donating N atoms bonding to the metal ion (Figure 23.8A). Such ligands seem to grab the metal ion like claws, so a complex ion that contains them is also called a **chelate** (pronounced “KEY-late”; Greek *chela*, “crab’s claw”). With its six donor atoms, the ethylenediaminetetraacetate (EDTA<sup>4-</sup>) ion forms very stable complexes with metal ions (Figure 23.8B). This property makes EDTA useful in treating *heavy-metal poisoning*. Ingested by the patient, the EDTA<sup>4-</sup> ion removes lead and other heavy-metal ions from the blood and other body fluids.

**Figure 23.8** Chelates. Structure (left) and model (right) of (A) the bidentate ligand ethylenediamine (*en*) complexed with a  $\text{Co}^{3+}$  ion and (B) the chelate  $[\text{Pb}(\text{EDTA})]^{2-}$ .

Table 23.6

Some Common Ligands in Coordination Compounds

Ligand Type	Examples
Monodentate	$\text{H}_2\ddot{\text{O}}:$ water
	$:\ddot{\text{F}}:^-$ fluoride ion
	$:\text{NH}_3$ ammonia
	$:\ddot{\text{Cl}}:^-$ chloride ion
Bidentate	
	ethylenediamine (en)
	
	oxalate ion
Polydentate	
	diethylenetriamine
	
	
	ethylenediaminetetraacetate ion ( $\text{EDTA}^{4-}$ )

The  $\text{EDTA}^{4-}$  ion is often added to products such as shampoos as it removes  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$  ions from hard water, allowing the shampoo to clean more efficiently.

Table 23.6 shows some common ligands in coordination compounds. Note that each ligand has one or more donor atoms (colored type), each with a lone pair of electrons to donate, thereby forming a covalent bond to the metal ion. Since the bidentate ligand ethylenediamine has two atoms that form bonds to the metal ion, the complex ion  $[\text{Co}(\text{en})_3]^{3+}$  has a coordination number of 6 (two covalent bonds per ligand); the complex ion  $[\text{Pb}(\text{EDTA})]^{2-}$  has one polydentate ligand with six donor atoms, so it also has a coordination number of 6.

## Formulas and Names of Coordination Compounds

The combination of ions in a coordination compound is the key to writing its formula and name. A coordination compound can consist of a complex cation with simple anionic counter ions, a complex anion with simple cationic counter ions, or even a complex cation with complex anion as counter ion.

**Determining the Charge of the Metal Ion** The charge of the complex ion can be determined from the charge of its counter ion(s) and basic arithmetic can be used to find the charge of the metal ion:

$$\text{Charge of metal ion} = \text{charge of complex ion} - \text{total charge of ligands} \quad (23.1)$$

- For a compound with a *complex anion*, say,  $\text{K}_2[\text{Co}(\text{NH}_3)_2\text{Cl}_4]$ , the two  $\text{K}^+$  counter ions (written outside the brackets) have a total charge of  $2 \times 1+ = 2+$  and balance the charge of the complex anion, which must have a charge of  $2-$ ; the complex ion contains two  $\text{NH}_3$  molecules and four  $\text{Cl}^-$  ions as ligands. The two  $\text{NH}_3$  are neutral, the four  $\text{Cl}^-$  have a total charge of  $4-$ . We can use Equation 23.1 to determine the charge of the central metal ion:

$$\begin{aligned} \text{Charge of metal ion} &= \text{charge of complex ion} - \text{total charge of ligands} \\ &= (2-) - [(2 \times 0) + (4 \times 1-)] \\ &= (2-) - (4-) = 2+; \text{ that is, } \text{Co}^{2+} \end{aligned}$$

- For a compound with a *complex cation*, say  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}$ , the  $\text{Cl}^-$  ion outside the brackets is the counter ion and the complex cation has a charge of  $1+$  to balance the  $1-$  charge of that counter ion. The complex ion  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$  has four  $\text{NH}_3$  ligands that are neutral and two  $\text{Cl}^-$  ligands with a total charge of  $2-$ , so the central metal ion must be  $\text{Co}^{3+}$ :

$$\begin{aligned} \text{Charge of metal ion} &= \text{charge of complex ion} - \text{total charge of ligands} \\ &= (1+) - [(4 \times 0) + (2 \times 1-)] = 3+ \end{aligned}$$

**Rules for Writing Formulas** There are four rules for writing formulas of coordination compounds (the first two are the same as those for the formula of any ionic compound):

1. The cation is written before the anion.
2. The charge of the cation(s) is balanced by the charge of the anion(s).
3. For the complex ion, neutral ligands are written (in alphabetical order) before anionic ligands (written in alphabetical order), and the formula of the whole ion is placed in brackets.
4. Counter ions are written outside the brackets.

**SAMPLE PROBLEM 23.3****Finding the Coordination Number and Charge of the Central Metal Ion in a Coordination Compound**

**Problem** Give the coordination number and the charge of the central metal ion in each coordination compound:

**Plan** To find the coordination number, we use Table 23.6 to determine the number of ligand atoms bonded to the central metal ion in the complex ion (in square brackets). Counter ions (those ions outside the brackets) are not included when determining the coordination number. We know that the charge of the complex ion must balance the charge of the counter ions; the charge of the metal ion is equal to the charge of the complex ion minus the total charge of the ligands.

**Solution** (a) Each of the four monodentate  $\text{OH}^-$  ligands forms one bond to the metal ion for a coordination number of 4. Since the two  $\text{Na}^+$  counter ions have a total charge of 2+, the charge of the complex ion is 2−; the four  $\text{OH}^-$  ligands have a total charge of 4−. The charge of the zinc ion is

$$\begin{aligned}\text{Charge of metal ion} &= \text{charge of complex ion} - \text{total charge of ligands} \\ &= (2-) - (4-) = 2+\end{aligned}$$

(b) There are two monodentate  $\text{H}_2\text{O}$  ligands, each forming one bond to the metal ion; since the two  $\text{C}_2\text{O}_4^{2-}$  ligands are bidentate, each of them forms two bonds to the metal ion, for a total of four bonds. Thus, the coordination number is 6. Since the  $\text{K}^+$  counter ion has a charge of 1+, the charge of the complex ion is 1−. The  $\text{H}_2\text{O}$  ligands are neutral, and the two  $\text{C}_2\text{O}_4^{2-}$  ligands have a total charge of 4−. The charge of the cobalt ion is

$$\text{Charge of metal ion} = (1-) - [0 + (4-)] = 3+$$

(c) The complex has two  $\text{H}_2\text{O}$ , two  $\text{NH}_3$ , and two  $\text{Cl}^-$  ligands, each of which forms one bond to the metal ion for a coordination number of 6. Since the  $\text{Br}^-$  counter ion has a 1− charge, the complex ion has a charge of 1+. The  $\text{H}_2\text{O}$  and  $\text{NH}_3$  ligands are neutral, and the two  $\text{Cl}^-$  ligands have a total charge of 2−. The charge of the ruthenium ion is

$$\text{Charge of metal ion} = (1+) - [0 + 0 + (2-)] = 3+$$

**Check** Be sure that the coordination number equals the sum of the number of monodentate ligands and twice the number of bidentate ligands. Be sure that the charges of the metal ion, ligands, and counter ions sum to zero.

**FOLLOW-UP PROBLEMS**

**23.3A** Give the coordination number and the charge of the central metal ion in each coordination compound:

**23.3B** Write the formula of the coordination compound composed of the following:

(a) A  $\text{Mn}^{2+}$  central ion with a coordination number of 6, cyanide ligands, and potassium counter ions

(b) A  $\text{Cu}^{2+}$  central ion with a coordination number of 4, ethylenediamine ligands, and sulfate as the counter ion

**Rules for Naming Coordination Compounds** Originally named after their discoverer or color, coordination compounds are named systematically according to a set of rules. Let's see how to name [Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]Cl and K<sub>2</sub>[Co(H<sub>2</sub>O)Br<sub>3</sub>Cl<sub>2</sub>]. As we go through the naming steps, refer to Tables 23.7 and 23.8.

1. *The cation is named before the anion.* Thus, we name the [Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]<sup>+</sup> ion before the Cl<sup>-</sup> counter ion.
2. *Within the complex ion, the ligands are named in alphabetical order before the metal ion.* In the [Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]<sup>+</sup> ion, four NH<sub>3</sub> and two Cl<sup>-</sup> are named before Co<sup>3+</sup>.
3. *Neutral ligands generally have the molecule name, but there are a few exceptions (Table 23.7). Anionic ligands drop the -ide and add -o after the root name;* thus, the anion name *fluoride* for an F<sup>-</sup> ion becomes the ligand name *fluoro*. The two ligands in [Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]<sup>+</sup> are *ammine* (NH<sub>3</sub>) and *chloro* (Cl<sup>-</sup>) with *ammine* coming before *chloro* alphabetically.
4. *A numerical prefix indicates the number of ligands of a particular type.* For example, *tetraammine* denotes *four* NH<sub>3</sub>, and *dichloro* denotes *two* Cl<sup>-</sup>. Other prefixes are *tri-*, *penta-*, and *hexa-*. But prefixes do *not* affect the alphabetical order: *tetraammine* comes before *dichloro*. For ligand names that include a numerical prefix (such as ethylenediamine), we use *bis* (2), *tris* (3), or *tetrakis* (4) to indicate the number of such ligands, followed by the ligand name in parentheses. For example, a complex ion that has two ethylenediamine ligands has *bis(ethylenediamine)* in its name.
5. *The oxidation state of the metal ion has a roman numeral (in parentheses) only if the metal ion can have more than one state.* Since cobalt can have +2 and +3 states, we add a III to name the complex ion. Thus, the compound is

tetraamminedichlorocobalt(III) chloride

The only typographical space in the name comes between cation and anion.

6. *If the complex ion is an anion, we drop the ending of the metal name and add -ate.* Thus, the name for K<sub>2</sub>[Co(H<sub>2</sub>O)Br<sub>3</sub>Cl<sub>2</sub>] is potassium aquatribromodichlorocobaltate(III). There are two K<sup>+</sup> counter ions, so the complex anion has a charge of 2-. The three Br<sup>-</sup> and two Cl<sup>-</sup> ligands have a total charge of 5-, so Co must be in the +3 oxidation state. For some metals, we use the Latin root with the -ate ending (Table 23.8). For example, the name for Na<sub>4</sub>[FeBr<sub>6</sub>] is sodium hexabromoferrate(II).

### Student Hot Spot

Student data indicate that you may struggle with naming coordination compounds. Access the Smartbook to view additional Learning Resources on this topic.

### SAMPLE PROBLEM 23.4

### Writing Names and Formulas of Coordination Compounds

- Problem** (a) What is the systematic name of Na<sub>3</sub>[AlF<sub>6</sub>]?  
 (b) What is the systematic name of [Co(en)<sub>2</sub>Cl<sub>2</sub>]NO<sub>3</sub>?  
 (c) What is the formula of tetraamminebromochloroplatinum(IV) chloride?  
 (d) What is the formula of hexaamminecobalt(III) tetrachloroferrate(III)?

**Plan** We use the rules presented above and the information in Tables 23.7 and 23.8.

**Solution** (a) The complex ion is [AlF<sub>6</sub>]<sup>3-</sup>. There are six (*hexa-*) F<sup>-</sup> ions (*fluoro*) as ligands, so we have *hexafluoro*. The complex ion is an anion, so the ending of the

metal ion (aluminum) must be changed to *-ate*: hexafluoroaluminate. Aluminum has only the +3 oxidation state, so we do *not* use a roman numeral. The positive counter ion is named first and separated from the name of the anion by a space: sodium hexafluoroaluminate.

(b) Listed alphabetically, there are two  $\text{Cl}^-$  (*dichloro*) and two en [*bis(ethylenediamine)*] as ligands. The complex ion is a cation, so the metal name is unchanged, but we specify its oxidation state because cobalt can have several. One  $\text{NO}_3^-$  balances the 1+ cation charge. With 2– for two  $\text{Cl}^-$  and 0 for two en, the metal must be *cobalt(III)*. The word *nitrate* follows a space: dichlorobis(ethylenediamine)cobalt(III) nitrate.

(c) The central metal ion is written first, followed by the neutral ligands and then (in alphabetical order) by the negative ligands. *Tetraammine* is four  $\text{NH}_3$ , *bromo* is one  $\text{Br}^-$ , *chloro* is one  $\text{Cl}^-$ , and *platinate(IV)* is  $\text{Pt}^{4+}$ , so the complex ion is  $[\text{Pt}(\text{NH}_3)_4\text{BrCl}]^{2+}$ . Its 2+ charge is the sum of 4+ for  $\text{Pt}^{4+}$ , 0 for four  $\text{NH}_3$ , 1– for one  $\text{Br}^-$ , and 1– for one  $\text{Cl}^-$ . To balance the 2+ charge, we need two  $\text{Cl}^-$  counter ions:  $[\text{Pt}(\text{NH}_3)_4\text{BrCl}]\text{Cl}_2$ .

(d) This compound consists of two different complex ions. In the cation, *hexaammine* is six  $\text{NH}_3$  and *cobalt(III)* is  $\text{Co}^{3+}$ , so the cation is  $[\text{Co}(\text{NH}_3)_6]^{3+}$ . The 3+ charge is the sum of 3+ for  $\text{Co}^{3+}$  and 0 for six  $\text{NH}_3$ . In the anion, *tetrachloro* is four  $\text{Cl}^-$ , and *ferrate(III)* is  $\text{Fe}^{3+}$ , so the anion is  $[\text{FeCl}_4]^-$ . The 1– charge is the sum of 3+ for  $\text{Fe}^{3+}$  and 4– for four  $\text{Cl}^-$ . In the neutral compound, one 3+ cation must be balanced by three 1– anions:  $[\text{Co}(\text{NH}_3)_6][\text{FeCl}_4]_3$ .

**Check** Reverse the process to be sure you obtain the name or formula in the problem.

### FOLLOW-UP PROBLEMS

**23.4A** (a) What is the name of  $[\text{Cr}(\text{H}_2\text{O})_5\text{Br}]\text{Cl}_2$ ? (b) What is the formula of barium hexacyanocobaltate(III)?

**23.4B** (a) What is the formula of diaquabis(ethylenediamine)cobalt(III) sulfate?

(b) What is the name of  $\text{Mg}[\text{Cr}(\text{NH}_3)_2\text{Cl}_4]_2$ ?

## Isomerism in Coordination Compounds

**Isomers** are compounds with the same chemical formula but different properties. Recall the discussion of isomerism in organic compounds (Section 15.2); coordination compounds exhibit the same two broad categories—constitutional isomers and stereoisomers.

**Constitutional Isomers: Atoms Connected Differently** Compounds with the same formula, but with the atoms connected differently, are **constitutional (structural) isomers**. Coordination compounds exhibit two types, *coordination* and *linkage* isomers:

1. **Coordination isomers** occur when the composition of the complex ions, but not of the compounds, is different. This type of isomerism occurs in two ways:

- *Exchange of ligand and counter ion.* The roles of the  $\text{Cl}^-$  ions and the  $\text{NO}_2^-$  ions are reversed in the following example:

In  $[\text{Pt}(\text{NH}_3)_4\text{Cl}_2](\text{NO}_2)_2$ , the  $\text{Cl}^-$  ions are the ligands, and the  $\text{NO}_2^-$  ions are counter ions;

In  $[\text{Pt}(\text{NH}_3)_4(\text{NO}_2)_2]\text{Cl}_2$ , the  $\text{NO}_2^-$  ions are the ligands, and the  $\text{Cl}^-$  ions are counter ions.

A common test to see whether  $\text{Cl}^-$  is a ligand or a counter ion is to treat a solution of the compound with  $\text{AgNO}_3$ ; the  $\text{Cl}^-$  counter ion will form a white precipitate of  $\text{AgCl}$ , but the  $\text{Cl}^-$  ligand won't. Thus, a solution of  $[\text{Pt}(\text{NH}_3)_4\text{Cl}_2](\text{NO}_2)_2$  does not form  $\text{AgCl}$  because  $\text{Cl}^-$  is bound to the metal ion, but a  $[\text{Pt}(\text{NH}_3)_4(\text{NO}_2)_2]\text{Cl}_2$  solution forms 2 mol of  $\text{AgCl}$  per mole of compound.

- *Exchange of ligands.* This type of isomerism occurs in compounds consisting of two complex ions. For example, in  $[\text{Cr}(\text{NH}_3)_6][\text{Co}(\text{CN})_6]$  and  $[\text{Co}(\text{NH}_3)_6][\text{Cr}(\text{CN})_6]$ ,  $\text{NH}_3$  is a ligand of  $\text{Cr}^{3+}$  in one compound and of  $\text{Co}^{3+}$  in the other.

**Figure 23.9** A pair of linkage (constitutional) isomers.

Source: © McGraw-Hill Education/Charles Winters/Timeframe Photography, Inc.

2. **Linkage isomers** occur when the composition of the complex ion is the same but the ligand donor atom is different. Some ligands can bind to the metal ion through *either of two donor atoms*. For example, the nitrite ion can bind through the N atom (*nitro*,  $\text{O}_2\text{N}:$ ) or either of the O atoms (*nitrito*,  $\text{ONO}:$ ) to give linkage isomers, such as pentaamminenitrocobalt(III) chloride  $[\text{Co}(\text{NH}_3)_5(\text{NO}_2)]\text{Cl}_2$  and pentaamminenitritocobalt(III) chloride  $[\text{Co}(\text{NH}_3)_5(\text{ONO})]\text{Cl}_2$  (Figure 23.9).

Other examples of ligands that have more than one donor atom are the cyanate ion, which can attach via the O atom (*cyanato*,  $\text{NCO}:$ ) or the N atom (*isocyanato*,  $\text{OCN}:$ ), and the thiocyanate ion, which can attach via the S atom (*thiocyanato*,  $\text{NCS}:$ ) or the N atom (*isothiocyanato*,  $\text{SCN}:$ ):

**Stereoisomers: Atoms Arranged Differently in Space** Stereoisomers are compounds that have the same atomic connections but different spatial arrangements of the atoms. *Geometric* and *optical* isomers, which we discussed for organic compounds, occur with coordination compounds as well:

1. **Geometric isomers** (also called *cis-trans* isomers, or *diastereomers*) occur when atoms or groups of atoms are arranged differently in space relative to the central metal ion. For example, the square planar  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$  has two arrangements, which give rise to two different compounds (Figure 23.10A). The isomer with identical ligands

**Figure 23.10** Geometric (*cis-trans*) isomerism. **A**, The *cis* and *trans* isomers of  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$ . **B**, The *cis* and *trans* isomers of  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$ . The colored shapes indicate the actual colors of the species.

next to each other is *cis*-diamminedichloroplatinum(II), and the one with identical ligands *across* from each other is *trans*-diamminedichloroplatinum(II).

These isomers have remarkably different biological behaviors. In the mid-1960s, Barnett Rosenberg and his colleagues found that *cis*-[Pt(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>] (cisplatin) was an antitumor agent. It and several closely related platinum(II) complexes are still used to treat certain types of cancer. In contrast, *trans*-[Pt(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>] has no antitumor effect. Cisplatin may work by becoming oriented within a cancer cell so that a donor atom on each DNA strand can replace a Cl<sup>-</sup> ligand and bind to the platinum strongly, preventing DNA replication (Section 15.6).

Octahedral complexes also exhibit *cis-trans* isomerism (Figure 23.10B). The *cis* isomer of the [Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]<sup>+</sup> ion has the two Cl<sup>-</sup> ligands at any two adjacent positions of the ion's octahedral shape, whereas the *trans* isomer has these ligands across from each other. Tetrahedral complexes do not exhibit this type of isomerism.

2. **Optical isomers** (also called *enantiomers*) occur when a molecule and its mirror image cannot be superimposed (see Figures 15.8 to 15.10). Unlike other types of isomers, which have distinct physical properties, optical isomers are physically identical except for *the direction in which they rotate the plane of polarized light*. Many octahedral complex ions show optical isomerism, which we can determine by rotating one isomer and seeing if it is superimposable on the other isomer (its mirror image). For example, in Figure 23.11A, the two structures (I and II) of *cis*-[Co(en)<sub>2</sub>Cl<sub>2</sub>]<sup>+</sup>, the *cis*-dichlorobis(ethylenediamine)cobalt(III) ion, are mirror images of each other. Rotate structure I clockwise 180° around a vertical axis, and you obtain III. The Cl<sup>-</sup> ligands of III match those of II, but the en ligands do not: II and III (which is I rotated) are not superimposable: they are optical isomers. One isomer is designated *d*-[Co(en)<sub>2</sub>Cl<sub>2</sub>]<sup>+</sup> and the other is *l*-[Co(en)<sub>2</sub>Cl<sub>2</sub>]<sup>+</sup>, indicating whether the isomer rotates polarized light to the right (*d*- for “dextro-”) or to the left (*l*- for “levo-”). (The *d*- or *l*- designation can only be determined by experiment.)

In contrast, as shown in Figure 23.11B, the two structures of the *trans*-dichlorobis(ethylenediamine)cobalt(III) ion are *not* optical isomers: rotate I 90°

**Figure 23.11** Optical isomerism in an octahedral complex ion. **A**, Structure I and its mirror image, structure II, are optical isomers of *cis*-[Co(en)<sub>2</sub>Cl<sub>2</sub>]<sup>+</sup>. (The curved wedges represent the bidentate ligand ethylenediamine, H<sub>2</sub>N—CH<sub>2</sub>—CH<sub>2</sub>—NH<sub>2</sub>.) **B**, The *trans* isomer does *not* have optical isomers.

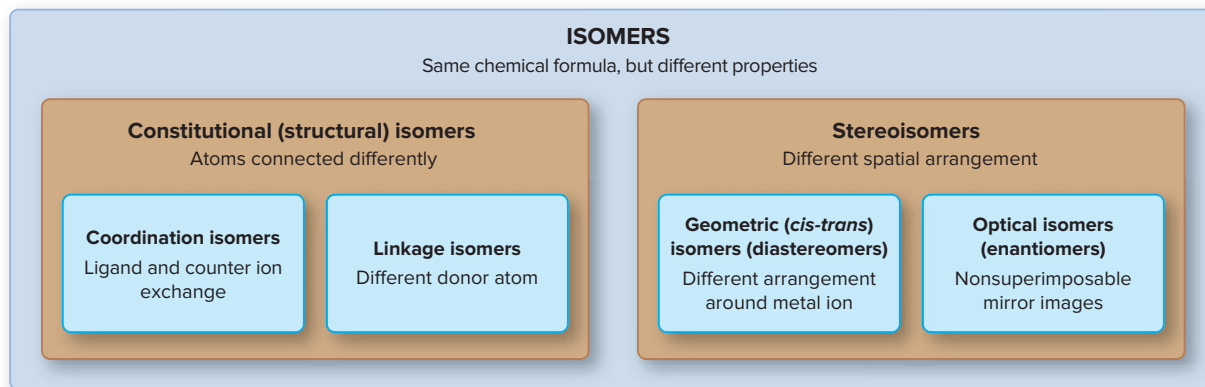

Figure 23.12 Important types of isomerism in coordination compounds.

counterclockwise around a vertical axis and you obtain III, which *is* superimposable on II.

Figure 23.12 is an overview of the most common types of isomerism in coordination compounds.

### SAMPLE PROBLEM 23.5

### Determining the Type of Stereoisomerism

**Problem** Draw stereoisomers for each of the following and state the type of isomerism:  
**(a)**  $[\text{Pt}(\text{NH}_3)_2\text{Br}_2]$  (square planar)      **(b)**  $[\text{Cr}(\text{en})_3]^{3+}$  (en =  $\text{H}_2\ddot{\text{N}}\text{CH}_2\text{CH}_2\ddot{\text{N}}\text{H}_2$ )

**Plan** We determine the geometry around each metal ion and the nature of the ligands. If there are different ligands that can be placed in different positions relative to each other, geometric (*cis-trans*) isomerism occurs. Then, we see whether the mirror image of an isomer is superimposable on the original. If it is *not*, optical isomerism also occurs.

**Solution (a)** The square planar Pt(II) complex has two different monodentate ligands. Each pair of ligands can lie next to or across from each other (*see margin*). Thus, geometric isomerism occurs. Each isomer *is* superimposable on a mirror image of itself, so there is no optical isomerism.

**(b)** Ethylenediamine (en) is a bidentate ligand. The  $\text{Cr}^{3+}$  has a coordination number of 6 and an octahedral geometry, like  $\text{Co}^{3+}$ . The three bidentate ligands are identical, so there is no geometric isomerism. However, the complex ion has a nonsuperimposable mirror image (*see margin*). Thus, optical isomerism occurs.

### FOLLOW-UP PROBLEMS

**23.5A** What stereoisomers, if any, are possible for the  $[\text{Co}(\text{NH}_3)_2(\text{en})\text{Cl}_2]^+$  ion?

**23.5B** Draw all of the stereoisomers of the  $[\text{Ru}(\text{H}_2\text{O})_2(\text{NH}_3)_2\text{Cl}_2]^+$  ion.

**SOME SIMILAR PROBLEMS** 23.63–23.66

## Summary of Section 23.3

- > Coordination compounds consist of a complex ion and charge-balancing counter ions. The complex ion has a central metal ion bonded to neutral and/or anionic ligands, which have one or more donor atoms that each have a lone pair of electrons.
- > The most common complex-ion geometry is octahedral (six ligand atoms bonding).
- > Formulas and names of coordination compounds follow systematic rules.
- > Coordination compounds can exhibit constitutional isomerism (coordination and linkage) and stereoisomerism (geometric and optical).

## 23.4 THEORETICAL BASIS FOR THE BONDING AND PROPERTIES OF COMPLEX IONS

In this section, we consider valence bond theory and crystal field theory, which address different features of complex ions: how metal-ligand bonds form, why certain geometries are preferred, and why these ions are brightly colored and often paramagnetic.

### Applying Valence Bond Theory to Complex Ions

*Valence bond (VB) theory*, which helps explain bonding and structure in main-group compounds (Section 11.1), can also be used to describe bonding in complex ions. In the formation of a complex ion, the *filled* ligand orbital overlaps an *empty* metal-ion orbital: *the ligand (Lewis base) donates an electron pair, and the metal ion (Lewis acid) accepts it to form a covalent bond in the complex ion (Lewis adduct)* (Section 18.9). A bond in which one atom contributes both electrons is a **coordinate covalent bond**; once formed, it is identical to any covalent single bond.

Recall that the VB concept of hybridization proposes mixing particular combinations of *s*, *p*, and *d* orbitals to obtain sets of hybrid orbitals, which have specific geometries. For coordination compounds, the model proposes that *the type of metal-ion orbital hybridization determines the geometry of the complex ion*. Let's discuss orbital combinations that lead to octahedral, square planar, and tetrahedral geometries.

**Octahedral Complexes** The hexaamminechromium(III) ion,  $[\text{Cr}(\text{NH}_3)_6]^{3+}$ , is an *octahedral complex* (Figure 23.13). The six lowest-energy, *empty* orbitals of the  $\text{Cr}^{3+}$  ion—two *3d*, one *4s*, and three *4p*—mix and become six equivalent  $d^2sp^3$  hybrid orbitals of an octahedron.\* Six  $\text{NH}_3$  molecules donate lone pairs from their N atoms to form six metal-ligand bonds. Three unpaired *3d* electrons of the central  $\text{Cr}^{3+}$  ion ( $[\text{Ar}] 3d^3$ ) remain in unhybridized orbitals and make the complex ion paramagnetic.

**Figure 23.13** Hybrid orbitals and bonding in the octahedral  $[\text{Cr}(\text{NH}_3)_6]^{3+}$  ion.

**Square Planar Complexes** Metal ions with a  $d^8$  configuration usually form *square planar complexes* (Figure 23.14, *next page*). In the  $[\text{Ni}(\text{CN})_4]^{2-}$  ion, for example, the model proposes that one *3d*, one *4s*, and two *4p* orbitals of  $\text{Ni}^{2+}$  mix and form four  $dsp^2$  hybrid orbitals, which point to the corners of a square and accept one electron pair from each of four  $\text{CN}^-$  ligands.

A look at the ground-state electron configuration of the  $\text{Ni}^{2+}$  ion, however, raises a key question: how can the  $\text{Ni}^{2+}$  ion ( $[\text{Ar}] 3d^8$ ) offer an empty *3d* orbital for accepting a lone pair, if its eight *3d* electrons lie in three filled and two half-filled orbitals? Apparently, in the  $d^8$  configuration of  $\text{Ni}^{2+}$ , electrons in the half-filled orbitals *pair up* and leave one *3d* orbital empty. This explanation is consistent with the fact that

\*Note the difference between hybrid-orbital designations here and in Chapter 11, even though both designations give the orbitals in energy order. In  $[\text{Cr}(\text{NH}_3)_6]^{3+}$ , the *3d* orbitals have a *lower n* value than the *4s* and *4p* orbitals, so the hybrid orbitals are  $d^2sp^3$ . But, for  $\text{SF}_6$ , the *3d* orbitals have the same *n* value as the *3s* and *3p* orbitals of S, so the designation is  $sp^3d^2$ .

**Figure 23.14** Hybrid orbitals and bonding in the square planar  $[\text{Ni}(\text{CN})_4]^{2-}$  ion.

the complex is diamagnetic (no unpaired electrons). Moreover, it means that the energy *gained* by using a 3d orbital for bonding in the hybrid orbital is greater than the energy *required* to overcome repulsions from pairing the 3d electrons.

**Tetrahedral Complexes** Metal ions that have a filled  $d$  sublevel, such as  $\text{Zn}^{2+}$  ( $[\text{Ar}] 3d^{10}$ ), often form diamagnetic *tetrahedral complexes* (Figure 23.15). In the  $[\text{Zn}(\text{OH})_4]^{2-}$  ion, for example, VB theory proposes that the lowest *empty*  $\text{Zn}^{2+}$  orbitals—one 4s and three 4p—mix to become four  $sp^3$  hybrid orbitals that point to the corners of a tetrahedron and are occupied by lone pairs, one from each of four  $\text{OH}^-$  ligands.

**Figure 23.15** Hybrid orbitals and bonding in the tetrahedral  $[\text{Zn}(\text{OH})_4]^{2-}$  ion.

## Crystal Field Theory

The VB model is easy to picture and rationalizes bonding and shape, but it treats the orbitals as little more than empty “slots” for accepting electron pairs. Moreover, it gives no insight into the colors of complex ions and sometimes predicts their magnetic properties incorrectly. For this reason, other models are applied more often. Although **crystal field theory** provides little insight about metal-ligand bonding, it explains color and magnetism by highlighting the *effect on d-orbital energies of the metal ion as the ligands approach*. Before we discuss the theory, let’s consider why a substance is colored.

**What Is Color?** White light consists of all wavelengths ( $\lambda$ ) in the visible range (Section 7.1) and can be dispersed into colors of a narrower wavelength range. Objects appear colored in white light because they absorb only certain wavelengths: an opaque object *reflects* the other wavelengths, and a clear one *transmits* them. If an object absorbs all visible wavelengths, it appears black; if it reflects all, it appears white.

Each color has a *complementary* color; for example, green and red are complementary colors. Figure 23.16 shows these relationships on an artist’s color wheel in which complementary colors are wedges opposite each other. A mixture of complementary colors absorbs all visible wavelengths and appears black.

An object has a particular color for one of two reasons:

- It reflects (or transmits) light of *that* color. Thus, if an object absorbs all wavelengths *except* green, the reflected (or transmitted) light is seen as green.
- It absorbs light of the *complementary* color. Thus, if the object absorbs only red, the *complement* of green, the remaining mixture of reflected (or transmitted) wavelengths is also seen as green.

**Figure 23.16** An artist’s wheel. Colors, with approximate wavelength ranges (in nm), are shown as wedges.

**Table 23.9** Relation Between Absorbed and Observed Colors

Absorbed Color	$\lambda$ (nm)	Observed Color	$\lambda$ (nm)
Violet	400	Green-yellow	560
Blue	450	Orange	600
Blue-green	490	Red	620
Yellow-green	570	Violet	410
Yellow	580	Dark blue	430
Orange	600	Blue	450
Red	650	Green	520

Table 23.9 lists the color absorbed and the resulting color observed. The relation between absorbed and observed colors is demonstrated by the seasonal colors of deciduous trees. In the spring and summer, leaves contain high concentrations of the photosynthetic pigment *chlorophyll* and lower concentrations of other pigments called *xanthophylls*. Chlorophyll absorbs strongly in the blue and red regions, reflecting mostly green. In the fall, photosynthesis slows, so the leaf no longer makes chlorophyll. The green fades as the chlorophyll decomposes, revealing the xanthophylls that were present but masked by the chlorophyll. Xanthophylls absorb green and blue strongly, reflecting bright yellows and reds (see photo).

**Splitting of  $d$  Orbitals in an Octahedral Field of Ligands** The crystal field model explains that the properties of complex ions result from the splitting of  $d$ -orbital energies, which arises from *electrostatic attractions between the metal cation and the negative charge of the ligands*. This negative charge is either partial, as in a polar covalent ligand like  $\text{NH}_3$ , or full, as in an anionic ligand like  $\text{Cl}^-$ . Picture six ligands approaching a metal ion along the mutually perpendicular  $x$ ,  $y$ , and  $z$  axes, to form an octahedral arrangement (Figure 23.17A). Let's follow the orientation of ligand and orbital and how the approach affects orbital energies.

1. *Orientation of ligand and metal-ion orbitals.* As ligands approach, their electron pairs repel electrons in the five  $d$  orbitals of the metal ion. In the isolated ion, the  $d$  orbitals have different orientations but *equal* energies. But, in the negative field of

**Figure 23.17** The five  $d$  orbitals in an octahedral field of ligands.

**Figure 23.18** Splitting of  $d$ -orbital energies in an octahedral field of ligands.

ligands, the  $d$  electrons are repelled *unequally* because of their different orbital orientations. The ligands moving along the  $x$ ,  $y$ , and  $z$  axes approach

- Directly toward the lobes of the  $d_{x^2-y^2}$  and  $d_{z^2}$  orbitals (Figure 23.17B and C).
- Between the lobes of the  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals (Figure 23.17D to F).

2. *Effect on  $d$ -orbital energies.* As a result of these different orientations, electrons in the  $d_{x^2-y^2}$  and  $d_{z^2}$  orbitals experience *stronger* repulsions than do electrons in the  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals. An energy diagram shows that the five  $d$  orbitals have the same energy and are most stable in the free ion and their *average* energy is higher in the ligand field. But *the orbital energies split*, with two  $d$  orbitals higher in energy and three lower (Figure 23.18):

- The two higher energy orbitals are  **$e_g$  orbitals** and arise from the  $d_{x^2-y^2}$  and  $d_{z^2}$  orbitals.
- The three lower energy orbitals are  **$t_{2g}$  orbitals** and arise from the  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals.

3. *The crystal field effect.* This splitting of orbital energies is called the *crystal field effect*, and the energy difference between  $e_g$  and  $t_{2g}$  orbitals is the **crystal field splitting energy ( $\Delta$ )**. Different ligands create crystal fields of different strength:

- **Strong-field ligands** lead to a *larger* splitting energy (larger  $\Delta$ ).
- **Weak-field ligands** lead to a *smaller* splitting energy (smaller  $\Delta$ ).

For instance,  $\text{H}_2\text{O}$  is a weak-field ligand, and  $\text{CN}^-$  is a strong-field ligand (Figure 23.19). Note the different orbital occupancies; we discuss the reason for these differences shortly.

**Explaining the Colors of Transition Metal Complexes** The color of a coordination compound is determined by  $\Delta$  of its complex ion. When the ion absorbs radiant energy, electrons can use that energy to move from the lower energy  $t_{2g}$  level to the higher energy  $e_g$  level. Recall from Section 7.2 that the *difference* between two atomic energy levels is equal to the energy (and inversely related to the wavelength) of the absorbed photon:

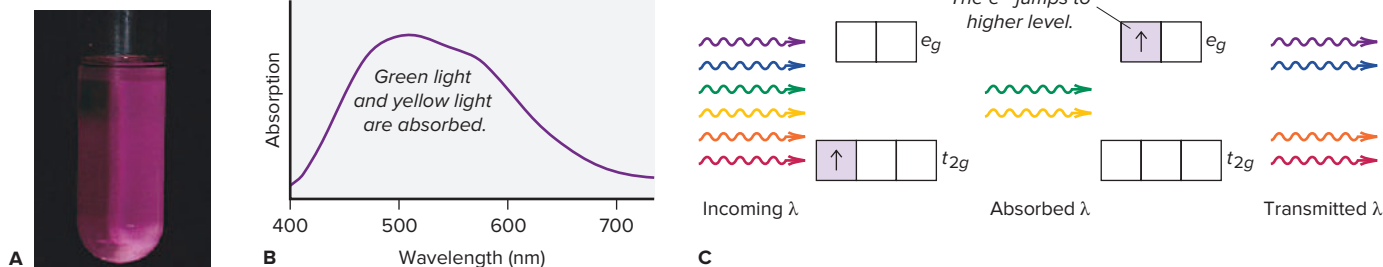

$$\Delta E_{\text{electron}} = E_{\text{photon}} = h\nu = hc/\lambda$$

Consider the  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  ion, which appears purple in aqueous solution (Figure 23.20). Hydrated  $\text{Ti}^{3+}$  has its one  $d$  electron in one of the three lower energy  $t_{2g}$  orbitals. The

**Figure 23.19** The effect of ligands on splitting energy and orbital occupancy.

### Student Hot Spot

Student data indicate that you may struggle with the concept of crystal field theory. Access the Smartbook to view additional Learning Resources on this topic.

**Figure 23.20** The color of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ . **A**, The hydrated  $\text{Ti}^{3+}$  ion is purple. **B**, An absorption spectrum shows that green light and yellow light are absorbed and other wavelengths are transmitted. **C**, An orbital diagram depicts the colors absorbed when the  $d$  electron jumps to the higher level.

Source: (A) © McGraw-Hill Education/Pat Watson, photographer

energy difference ( $\Delta$ ) between the  $t_{2g}$  and  $e_g$  orbitals in this ion corresponds to the energy of photons in the green-to-yellow range of visible light. When white light shines on the solution, these colors of light are absorbed, and the electron uses that energy to jump to one of the  $e_g$  orbitals. Red, blue, and violet light are transmitted, so the solution appears purple.

Absorption spectra can show the wavelengths absorbed by (1) different metal ions with the same ligand and (2) a metal ion with different ligands. Such data allow us to relate the energy of the absorbed light to  $\Delta$  and make two key observations:

- For a given ligand, color depends on the *oxidation state of the metal ion*. The higher a metal's oxidation state, the larger the crystal field splitting energy and the greater the energy of visible light that must be absorbed to move an electron from the  $t_{2g}$  level to the  $e_g$  level. For example,  $[\text{V}(\text{H}_2\text{O})_6]^{2+}(\text{aq})$ , with vanadium in an oxidation state of +2, absorbs in the yellow range and is violet in color, while  $[\text{V}(\text{H}_2\text{O})_6]^{3+}(\text{aq})$  with vanadium in an oxidation state of +3 absorbs in the higher energy violet range and is yellow in color (Figure 23.21A).
- For a given metal ion, color depends on the *ligand*. A single ligand substitution can affect the wavelengths absorbed and, thus, the color. For example, replacing one  $\text{NH}_3$  ligand in the yellow  $[\text{Cr}(\text{NH}_3)_6]^{3+}$  ion with a  $\text{Cl}^-$  ligand results in a purple  $[\text{Cr}(\text{NH}_3)_5\text{Cl}]^{2+}$  ion (Figure 23.21B).

**The Spectrochemical Series** The fact that color depends on the ligand allows us to create a **spectrochemical series**, which ranks the ability of a ligand to split  $d$ -orbital energies (Figure 23.22). Using this series, we can predict the *relative* magnitude of  $\Delta$  for a series of octahedral complexes of a *given* metal ion. As  $\Delta$  increases, higher energies (shorter wavelengths) of light must be absorbed to excite electrons. Although we cannot predict the actual color of a given complex ion, we can determine whether it will absorb longer or shorter wavelengths than other complexes with different ligands.

### SAMPLE PROBLEM 23.6

### Ranking Crystal Field Splitting Energies ( $\Delta$ ) for Complex Ions of a Metal

**Problem** Rank  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ ,  $[\text{Ti}(\text{CN})_6]^{3-}$ , and  $[\text{Ti}(\text{NH}_3)_6]^{3+}$  in terms of  $\Delta$  and of the energy of visible light absorbed.

**Plan** The formulas show that Ti has the same oxidation state (+3) in the three ions. Using Figure 23.22, we rank the ligands by crystal field strength: the stronger the ligand, the greater the splitting, and the higher the energy of light absorbed.

**Solution** The ligand field strength is in the order  $\text{CN}^- > \text{NH}_3 > \text{H}_2\text{O}$ , so the relative size of  $\Delta$  and energy of light absorbed is

### FOLLOW-UP PROBLEMS

**23.6A** Which complex ion absorbs visible light of higher energy,  $[\text{V}(\text{H}_2\text{O})_6]^{3+}$  or  $[\text{V}(\text{NH}_3)_6]^{3+}$ ?

**Figure 23.21** Effects of oxidation state and ligand on color. **A**, Solutions of two hydrated vanadium ions. **B**, A change in one ligand can influence the color.

**Figure 23.22** The spectrochemical series. For reference, water is a weak-field ligand.

**23.6B** Some of the complex ions that  $\text{Co}^{3+}$  forms are  $[\text{Co}(\text{en})_3]^{3+}$ ,  $[\text{Co}(\text{NH}_3)_5\text{Cl}]^{2-}$ ,  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$ , and  $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]^{3+}$ . The observed colors of these ions (listed in arbitrary order) are red, green, purple, and yellow. Match each complex ion with its color.

**SOME SIMILAR PROBLEMS** 23.92–23.95, 23.97, and 23.98

**Explaining the Magnetic Properties of Transition Metal Complexes** Splitting of energy levels gives rise to magnetic properties based on the number of *unpaired* electrons in the metal ion's  $d$  orbitals. Based on Hund's rule, electrons occupy orbitals of equal energy one at a time. When all lower energy orbitals are half-filled, one of two situations occurs:

- The next electron can enter a half-filled orbital and pair up by overcoming a repulsive *pairing energy* ( $E_{\text{pairing}}$ ).
- The next electron can enter an empty, higher energy orbital by overcoming  $\Delta$ .

Thus, *the relative sizes of  $E_{\text{pairing}}$  and  $\Delta$  determine the occupancy of  $d$  orbitals*, which determines the number of unpaired electrons and, thus, the magnetic behavior of the ion.

As an example, the isolated  $\text{Mn}^{2+}$  ion ( $[\text{Ar}] 3d^5$ ) has five unpaired electrons of equal energy (Figure 23.23A). In an octahedral field of ligands, orbital occupancy is affected by the ligand in one of two ways:

- *Weak-field ligands and high-spin complexes.* Weak-field ligands, such as  $\text{H}_2\text{O}$  in  $[\text{Mn}(\text{H}_2\text{O})_6]^{2+}$ , cause a *small* splitting energy, so it takes *less* energy for  $d$  electrons to jump to the  $e_g$  set and stay unpaired than to pair up in the  $t_{2g}$  set (Figure 23.23B). Thus, for weak-field ligands,  $E_{\text{pairing}} > \Delta$ . Therefore, *the number of unpaired electrons in the complex ion is the same as in the free ion*: weak-field ligands create **high-spin complexes**, those with the *maximum* number of unpaired electrons.
- *Strong-field ligands and low-spin complexes.* In contrast, strong-field ligands, such as  $\text{CN}^-$  in  $[\text{Mn}(\text{CN})_6]^{4-}$ , cause a *large* splitting energy, so it takes *more* energy for electrons to jump to the  $e_g$  set than to pair up in the  $t_{2g}$  set (Figure 23.23C). Thus, for strong-field ligands,  $E_{\text{pairing}} < \Delta$ . Therefore, *the number of unpaired electrons in the complex ion is less than in the free ion*. Strong-field ligands create **low-spin complexes**, those with *fewer* unpaired electrons.

Orbital diagrams for  $d^1$  through  $d^9$  ions in octahedral complexes show that high-spin and low-spin options are possible only for  $d^4$ ,  $d^5$ ,  $d^6$ , and  $d^7$  ions (Figure 23.24). With three  $t_{2g}$  orbitals available,  $d^1$ ,  $d^2$ , and  $d^3$  ions always form high-spin complexes because there is no need to pair up. Similarly,  $d^8$  and  $d^9$  ions always form high-spin complexes because the  $t_{2g}$  set is filled with six electrons, so the  $e_g$  orbitals *must* have either two ( $d^8$ ) or one ( $d^9$ ) unpaired electron(s).

### Student Hot Spot

Student data indicate that you may struggle with determining the number of unpaired electrons in high-spin vs. low-spin complex ions. Access the Smartbook to view additional Learning Resources on this topic.

**Figure 23.23** High-spin and low-spin octahedral complex ions of  $\text{Mn}^{2+}$ .

## SAMPLE PROBLEM 23.7

## Identifying High-Spin and Low-Spin Complex Ions

**Problem** Iron(II) forms a complex in hemoglobin. For each of the two octahedral complex ions  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$  and  $[\text{Fe}(\text{CN})_6]^{4-}$ , draw an energy diagram showing orbital splitting, predict the number of unpaired electrons, and identify the ion as low spin or high spin.

**Plan** The  $\text{Fe}^{2+}$  electron configuration shows the number of  $d$  electrons, and the spectrochemical series (Figure 23.22) shows the relative ligand strengths. We draw energy diagrams, in which the  $t_{2g}$  and  $e_g$  orbital sets are farther apart (larger energy difference) for the strong-field ligand. Then we add electrons, noting that a weak-field ligand gives the *maximum* number of unpaired electrons and a high-spin complex, whereas a strong-field ligand gives the *minimum* number of unpaired electrons and a low-spin complex.

**Solution**  $\text{Fe}^{2+}$  has the  $[\text{Ar}] 3d^6$  configuration.  $\text{H}_2\text{O}$  produces smaller splitting than  $\text{CN}^-$ . The energy diagrams are shown below. The  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$  ion has four unpaired electrons (high spin), and the  $[\text{Fe}(\text{CN})_6]^{4-}$  ion has no unpaired electrons (low spin).

**Comment 1.**  $\text{H}_2\text{O}$  is a weak-field ligand, so it forms high-spin complexes. **2.** We cannot confidently predict the spin of a complex without having actual values for  $\Delta$  and  $E_{\text{pairing}}$ . **3.** Cyanide ions and carbon monoxide are toxic because they bind to the iron complexes in proteins involved in cellular energy (see the Chemical Connections at the end of Chapter 21 and the upcoming Chemical Connections).

## FOLLOW-UP PROBLEMS

**23.7A** How many unpaired electrons do you expect for  $[\text{Mn}(\text{CN})_6]^{3-}$ ? Is this a high-spin or low-spin complex ion?

**23.7B** How many unpaired electrons do you expect for  $[\text{CoF}_6]^{3-}$ ? Is this a high-spin or low-spin complex ion?

**SOME SIMILAR PROBLEMS** 23.88–23.91

**Crystal Field Splitting in Tetrahedral and Square Planar Complexes** Four ligands around a metal ion also cause  $d$ -orbital splitting, but the magnitude and pattern of the splitting depend on whether the ligands approach from a tetrahedral or a square planar orientation.

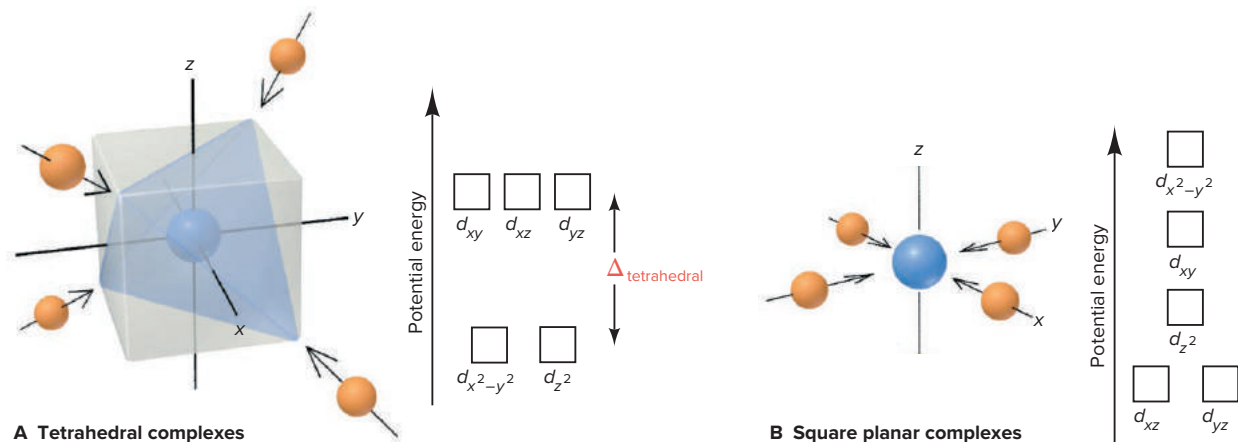

1. *Tetrahedral complexes.* When the ligands approach from the corners of a tetrahedron, none of the five  $d$  orbitals is directly in their paths (Figure 23.25A, next page). Thus, the overall attraction of ligand and metal ion is weaker, so the splitting of  $d$ -orbital energies is *less* in a tetrahedral than in an octahedral complex with the same ligands:

$$\Delta_{\text{tetrahedral}} < \Delta_{\text{octahedral}}$$

Repulsions are minimized when the ligands approach the  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals closer than they do the  $d_{x^2-y^2}$  and  $d_z^2$  orbitals. This situation is the *opposite of the octahedral case*, so the relative  $d$ -orbital energies are reversed: the  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals become *higher* in energy than the  $d_{x^2-y^2}$  and  $d_z^2$  orbitals. *Only high-spin tetrahedral complexes are known* because the magnitude of  $\Delta$  is always smaller than  $E_{\text{pairing}}$ , regardless of the ligand.

**Figure 23.24** Orbital occupancy for high-spin and low-spin octahedral complexes of  $d^4$  through  $d^7$  metal ions.

**Figure 23.25** Splitting of  $d$ -orbital energies. **A**, The pattern of splitting by a tetrahedral field of ligands is the opposite of the octahedral pattern. **B**, Splitting by a square planar field of ligands decreases the energies of  $d_{xz}$ ,  $d_{yz}$ , and especially  $d_{z^2}$  orbitals relative to the octahedral pattern.

2. *Square planar complexes.* The effects of the ligand field in the square planar case are easier to picture if we imagine starting with an octahedral geometry and then removing the two ligands along the  $z$ -axis (Figure 23.25B). With no  $z$ -axis interactions present, any  $d$  orbital with a  $z$ -axis component has lower energy, with the  $d_{z^2}$  orbital decreasing most, and the  $d_{xz}$  and  $d_{yz}$  also decreasing. In contrast, the two  $d$  orbitals in the  $xy$ -plane interact strongly with the ligands, and because the  $d_{x^2-y^2}$  orbital has its lobes *on* the axes, its energy is highest. The  $d^8$  metal ions form square planar complexes, such as  $[\text{PdCl}_4]^{2-}$ . They are *low spin* and usually *diamagnetic* because the four pairs of  $d$  electrons fill the four lowest-energy orbitals.

**A Final Word About Bonding Theories** As you have seen in several other cases, no one model is satisfactory in every respect. For complex ions, VB theory offers a simple picture of bond formation but does not even attempt to explain spectral and magnetic behavior of complexes. Crystal field theory predicts those two behaviors but offers no insight into the covalent nature of metal-ligand bonding. Thus, chemists now rely on the more comprehensive and quantitative *ligand field theory*, which combines aspects of the previous two models with MO theory (Section 11.3). While beyond the scope of this text, this powerful model predicts bond properties from the overlap of metal ion and ligand orbitals as well as the spectral and magnetic properties resulting from the splitting of the metal ion's  $d$  orbitals.

In addition to their important chemical applications, complexes of the transition elements play vital roles in living systems, as the following Chemical Connections essay describes.

### › Summary of Section 23.4

- › According to valence bond theory, complex ions have coordinate covalent bonds between ligands (Lewis bases) and metal ions (Lewis acids).
- › Ligand lone pairs occupy hybridized metal-ion orbitals, leading to the characteristic shapes of complex ions.
- › According to crystal field theory, the surrounding field of ligands splits a metal ion's  $d$ -orbital energies. The crystal field splitting energy ( $\Delta$ ) depends on the charge of the metal ion and the crystal field strength of the ligands.
- ›  $\Delta$  influences the color (energy of the photons absorbed) and paramagnetism (number of unpaired  $d$  electrons) of a complex ion. Strong-field ligands create a large  $\Delta$  and produce low-spin complexes that absorb light of higher energy (shorter wavelength); the reverse is true of weak-field ligands.
- › Several transition metals, including iron and zinc, are essential dietary components in trace amounts because they are crucial to the biochemical function of key proteins.

Living things consist primarily of water and complex organic compounds made of four *building-block elements* C, O, H, and N. They also contain seven other elements, known as *macronutrients* because of their fairly high concentrations. These macronutrients are (listed in order of atomic number): Na, Mg, P, S, Cl, K, and Ca. In addition, organisms contain a large number of elements in low concentrations, and most of these *micronutrients*, or *trace elements*, are transition metals.

With the exception of scandium and titanium, all Period 4 transition elements are essential to organisms (Table B23.1, *next page*), and plants also require molybdenum (from Period 5). A transition metal ion typically lies next to a protein chain covalently bonded to surrounding amino acid R groups whose N and O atoms act as ligands. Despite the complexity of biomolecules, the principles of bonding and *d*-orbital splitting are the same as in simple inorganic systems. In this discussion, we focus on iron and zinc.

### Iron and the Heme Group

Iron plays a crucial role in oxygen transport in all vertebrates. The oxygen-transporting protein hemoglobin (Figure B23.1A) consists of four folded protein chains called *globins*, each cradling the iron-containing complex *heme*. Each heme complex has an  $\text{Fe}^{2+}$  ion at the center of a tetradentate ring ligand *porphyrin* and bonded to the ligand's four N lone pairs to form a *square planar* complex. When heme is bound in hemoglobin, the complex becomes *square*

*pyramidal*, with an N atom from a nearby amino acid (histidine) as the fifth ligand. Hemoglobin exists in two forms, depending on the presence of  $\text{O}_2$ , which acts as a sixth ligand:

- *In the lungs*, where  $[\text{O}_2]$  is high, heme binds  $\text{O}_2$  to form *oxyhemoglobin*, which is transported in the arteries to tissues. With  $\text{O}_2$  bound, heme exists as part of an *octahedral* complex (Figure B23.1B). Since  $\text{O}_2$  is a strong-field ligand, the  $d^6 \text{Fe}^{2+}$  ion is part of a low-spin complex. Because of the relatively large *d*-orbital splitting, oxyhemoglobin absorbs blue (high-energy) light, so arterial blood is bright red.
- *At the tissues*, where  $[\text{O}_2]$  is low, the bound  $\text{O}_2$  is released, and *deoxyhemoglobin* forms, which is transported in the veins back to the lungs. Without the  $\text{O}_2$ , the  $\text{Fe}^{2+}$  ion is part of a high-spin complex, which has relatively small *d*-orbital splitting. Thus, deoxyhemoglobin absorbs red (low-energy) light, and venous blood is dark, purplish red.

The relative position of  $\text{Fe}^{2+}$  in the plane of the porphyrin ring also depends on the presence of the sixth ligand. Bound to  $\text{O}_2$ ,  $\text{Fe}^{2+}$  moves *into* the porphyrin plane; when  $\text{O}_2$  is released, it moves slightly *out of* the plane. This tiny (60 pm) change due to the binding or release of  $\text{O}_2$  alters the shape of the globin chain. And this change in shape alters the shape of the next globin chain, triggering the release or attachment of *its*  $\text{O}_2$ , and so on to the other two globin chains. This “cooperation” among the four globin chains allows hemoglobin to rapidly pick up  $\text{O}_2$  from the lungs and unload it rapidly in the tissues.

**Figure B23.1** Hemoglobin and the octahedral complex in heme. **A**, Hemoglobin consists of four protein chains, each with a bound heme. **B**, In oxyhemoglobin, the octahedral complex in heme has an  $\text{O}_2$  molecule as the sixth ligand of iron(II).

(continued)

Table B23.1 Some Transition Metal Trace Elements in Humans

Element	Biomolecule(s) Containing Element	Function(s) of Biomolecule(s)
Vanadium	Protein (?)	Redox couple in fat metabolism (?)
Chromium	Glucose tolerance factor	Glucose utilization
Manganese	Isocitrate dehydrogenase	Cell respiration
Iron	Hemoglobin and myoglobin Cytochrome <i>c</i> Catalase	Oxygen transport Cell respiration; ATP formation Decomposition of H <sub>2</sub> O <sub>2</sub>
Cobalt	Cobalamin (vitamin B <sub>12</sub> )	Development of red blood cells
Copper	Ceruloplasmin Cytochrome oxidase	Hemoglobin synthesis Cell respiration; ATP formation
Zinc	Carbonic anhydrase Carboxypeptidase A Alcohol dehydrogenase	Elimination of CO <sub>2</sub> Protein digestion Metabolism of ethanol

Heme binding of O<sub>2</sub> is an equilibrium process. Carbon monoxide is toxic because it binds to Fe<sup>2+</sup> about 200 times more tightly than O<sub>2</sub> does; each CO that binds eliminates one heme group from functioning. Like O<sub>2</sub>, CO is a strong-field ligand and produces a bright red, “healthy” look in the poisoned individual. Because binding is reversible, breathing high concentrations of O<sub>2</sub> displaces CO from the heme:

Porphyrin is a very common biological ligand. Chlorophyll has Mg<sup>2+</sup> and vitamin B<sub>12</sub> has Co<sup>3+</sup> at the center of a very similar ring system. Heme itself is found not only in hemoglobin, but also in proteins called *cytochromes* that are involved in energy metabolism (see Chemical Connections at end of Chapter 21).

### Zinc and the Enzyme Active Site

The zinc ion occurs at the active sites of several enzymes. With its *d*<sup>10</sup> configuration, Zn<sup>2+</sup> forms tetrahedral complexes with the N atoms of three amino acid groups at three positions, and the fourth position is free to interact with the molecule undergoing reaction (Figure B23.2). In its role as Lewis acid, Zn<sup>2+</sup> accepts a lone pair from the reactant as a step in the catalytic process. Consider the enzyme carbonic anhydrase, which catalyzes the reaction between H<sub>2</sub>O and CO<sub>2</sub> during respiration:

The Zn<sup>2+</sup> at the active site binds three histidine N atoms, and the O of the reactant H<sub>2</sub>O is the fourth donor atom. By withdrawing electron density from the O—H bonds, the Zn<sup>2+</sup> makes the H<sub>2</sub>O acidic enough to lose a proton. In the rate-determining step, the bound OH<sup>−</sup> ion is attracted to the partially positive C of CO<sub>2</sub> much more strongly than the lone pair of a free water molecule would be; thus, the reaction rate is higher. One reason Cd<sup>2+</sup> is toxic is that it competes with Zn<sup>2+</sup> for the carbonic anhydrase active site.

Figure B23.2 The tetrahedral Zn<sup>2+</sup> complex in carbonic anhydrase.

### Problems

**B23.1** (a) Identify each compound's central metal ion and give its oxidation state: chlorophyll, heme, and vitamin B<sub>12</sub>. (b) What similarity in structure do these compounds have?

**B23.2** Suggest a structural reason why carbonic anhydrase synthesized with Ni<sup>2+</sup>, Fe<sup>2+</sup>, or Mn<sup>2+</sup> in place of Zn<sup>2+</sup> has less catalytic efficiency.

## CHAPTER REVIEW GUIDE

### Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

#### Understand These Concepts

1. The positions of the *d*- and *f*-block elements and the general forms of their atomic and ionic electron configurations (§23.1)
2. How atomic size, ionization energy, and electronegativity vary across a period and down a group of transition elements and how these trends differ from those of the main-group elements; why the densities of Period 6 transition elements are so high (§23.1)
3. Why the transition elements often have multiple oxidation states and why the +2 state is common (§23.1)
4. Why metallic behavior (prevalence of ionic bonding and basic oxides) of transition elements decreases as oxidation state increases; how valence-state electronegativity explains transition metal atoms in oxoanions (§23.1)
5. Why many transition metal compounds are colored and paramagnetic (§23.1)
6. The common +3 oxidation state of the lanthanides and the similarity of the radii of their  $M^{3+}$  ions; the radioactivity of the actinides (§23.2)
7. The coordination numbers, geometries, and ligand structures of complex ions (§23.3)
8. How coordination compounds are named and their formulas written (§23.3)
9. The types of constitutional isomerism (coordination and linkage) and stereoisomerism (geometric and optical) of complex ions (§23.3)
10. How valence bond theory uses hybridization to account for the shapes of octahedral, square planar, and tetrahedral complexes (§23.4)
11. How crystal field theory explains that approaching ligands cause *d*-orbital energies to split (§23.4)
12. How the relative crystal field strength of ligands (spectrochemical series) affects the *d*-orbital splitting energy ( $\Delta$ ) (§23.4)

13. How the magnitude of  $\Delta$  accounts for the energy of light absorbed and, thus, the color of a complex ion (§23.4)
14. How the relative sizes of pairing energy and  $\Delta$  determine the occupancy of *d* orbitals and, thus, the magnetic properties of complex ions (§23.4)
15. How *d*-orbital splitting in tetrahedral and square planar complexes differs from that in octahedral complexes (§23.4)

#### Master These Skills

1. Writing electron configurations of transition metal atoms and ions (SP 23.1)
2. Using a partial orbital diagram to determine the number of unpaired electrons in a transition metal atom or ion (SP 23.2)
3. Recognizing the structural components of complex ions (§23.3)
4. Determining the coordination number and charge of the central metal ion in a coordination compound (SP 23.3)
5. Naming and writing formulas of coordination compounds (SP 23.4)
6. Determining the type of stereoisomerism in complexes (SP 23.5)
7. Correlating a complex ion's shape with the number and type of hybrid orbitals of the central metal ion (§23.4)
8. Using the spectrochemical series to rank complex ions in terms of  $\Delta$  and the energy of visible light absorbed (SP 23.6)
9. Using the spectrochemical series to determine if a complex ion is high spin or low spin (SP 23.7)

### Key Terms

Page numbers appear in parentheses.

actinides (1044)	coordination number (1046)	high-spin complex (1060)	low-spin complex (1060)
chelate (1047)	counter ion (1046)	inner transition	optical isomers (1053)
complex ion (1046)	crystal field splitting	elements (1044)	spectrochemical series (1059)
constitutional (structural)	energy ( $\Delta$ ) (1058)	isomer (1051)	stereoisomers (1052)
isomers (1051)	crystal field theory (1056)	lanthanide contraction (1041)	strong-field ligand (1058)
coordinate covalent	donor atom (1047)	lanthanides (1044)	$t_{2g}$ orbital (1058)
bond (1055)	$e_g$ orbital (1058)	ligand (1046)	transition elements (1037)
coordination compound (1046)	geometric ( <i>cis-trans</i> )	linkage isomers (1052)	weak-field ligand (1058)
coordination isomers (1051)	isomers (1052)		

### Key Equation and Relationship

Page number appears in parentheses.

**23.1** Finding the charge of the metal ion in a complex anion or cation (1048):

$$\text{Charge of metal ion} = \text{charge of complex ion} - \text{total charge of ligands}$$

## BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

**23.1A** (a) Ag:  $5s^1 4d^{10}$ ;  $\text{Ag}^+$ :  $4d^{10}$  (b) Cd:  $5s^2 4d^{10}$ ;  $\text{Cd}^{2+}$ :  $4d^{10}$   
 (c) Ir:  $6s^2 5d^7$ ;  $\text{Ir}^{3+}$ :  $5d^6$

**23.1B** (a) Ta:  $[\text{Xe}] 6s^2 4f^{14} 5d^3$ ; three electrons have been lost:  $\text{Ta}^{3+}$   
 (b) Mn:  $[\text{Ar}] 4s^2 3d^5$ ; four electrons have been lost:  $\text{Mn}^{4+}$   
 (c) Os:  $[\text{Xe}] 6s^2 4f^{14} 5d^6$ ; three electrons have been lost:  $\text{Os}^{3+}$

**23.2A** Er:  $[\text{Xe}] 6s^2 4f^{12}$ ;  $\text{Er}^{3+}$  is  $[\text{Xe}] 4f^{11}$ ; three unpaired electrons

**23.2B** Dy:  $[\text{Xe}] 6s^2 4f^{10}$ ;  $\text{Dy}^{3+}$  is  $[\text{Xe}] 4f^9$ ; five unpaired electrons

**23.3A** (a) Each en bidentate ligand forms two bonds to the metal ion, for a total of four bonds; the two monodentate  $\text{Br}^-$  ligands form a total of two bonds: coordination number = 6. The complex ion has a charge of 1+:

Charge of metal ion = charge of complex ion  
 – total charge of ligands  
 $= (1+) - [(2 \times 0) + (2 \times 1-)] = 3+$ ;  $\text{Co}^{3+}$

(b) The complex has six monodentate ligands: coordination number = 6; three  $\text{Mg}^{2+}$  counter ions have a total charge of 6+; each of the two complex ions has a charge of 3-:

Charge of metal ion = charge of complex ion  
 – total charge of ligands  
 $= (3-) - [(6 \times 1-)] = 3+$ ;  $\text{Cr}^{3+}$

**23.3B** (a)  $\text{K}_4[\text{Mn}(\text{CN})_6]$  (b)  $[\text{Cu}(\text{en})_2]\text{SO}_4$

**23.4A** (a) Five (*penta-*)  $\text{H}_2\text{O}$  (*aqua*) ligands, one  $\text{Br}^-$  (*bromo*) ligand, and the  $\text{Cr}^{3+}$  ion in the complex ion with  $\text{Cl}^-$  counter ions: Penta-aquabromochromium(III) chloride

(b) Hexacyano:  $(\text{CN})_6$ ; charge of complex ion = 3+ [from  $\text{Co}(\text{III})$ ] + (6-) [from  $(\text{CN})_6$ ] = 3-; three 2+ barium counter ions are needed to balance the charge of two 3- complex ions:  $\text{Ba}_3[\text{Co}(\text{CN})_6]_2$

**23.4B** (a) Two (*di-*) water (*aqua*) and two (*bis*) en ligands; charge of complex ion = 3+ [from  $\text{Co}(\text{III})$ ] + 2(0) [from  $(\text{H}_2\text{O})_2$ ] and 2(0) [from  $(\text{en})_2$ ] = 3+; three  $\text{SO}_4^{2-}$  counter ions are needed to balance the charge of two 3+ complex ions:  $[\text{Co}(\text{H}_2\text{O})_2(\text{en})_2]_2(\text{SO}_4)_3$

(b) Two (*di-*)  $\text{NH}_3$  (*ammine*) and four (*tetra-*)  $\text{Cl}^-$  (*chloro*) ligands and the  $\text{Cr}^{3+}$  ion with  $\text{Mg}^{2+}$  as the counter ion: magnesium diamminetetrachlorochromate(III)

**23.5A** Two sets of *cis-trans* isomers, and the two *cis* isomers are optical isomers.

**23.5B** Five geometric isomers; the *cis* isomer has an optical isomer.

**23.6A** Both metal ions are  $\text{V}^{3+}$ ; in terms of ligand field energy,  $\text{NH}_3 > \text{H}_2\text{O}$ , so  $[\text{V}(\text{NH}_3)_6]^{3+}$  absorbs light of higher energy.

**23.6B** In terms of ligand field energy and energy of light absorbed,  $\text{en} > \text{NH}_3 > \text{H}_2\text{O} > \text{Cl}^-$ ;  $[\text{Co}(\text{en})_3]^{3+}$  is yellow (violet light absorbed),  $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]^{3+}$  is red (green light absorbed),  $[\text{Co}(\text{NH}_3)_4\text{Cl}]^{2+}$  is purple (yellow light absorbed), and  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$  is green (red light absorbed). As weaker field ligands replace stronger field ligands, the energy of light absorbed decreases.

**23.7A** The metal ion is  $\text{Mn}^{3+}$ :  $[\text{Ar}] 3d^4$ ;  $\text{CN}^-$  is a strong-field ligand:

Two unpaired *d* electrons; low-spin complex

**23.7B** The metal ion is  $\text{Co}^{3+}$ :  $[\text{Ar}] 3d^6$ ;  $\text{F}^-$  is a weak-field ligand:

Four unpaired *d* electrons; high-spin complex

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

**Note:** In these problems, the term *electron configuration* refers to the condensed, ground-state electron configuration.

### Properties of the Transition Elements

(Sample Problem 23.1)

#### Concept Review Questions

**23.1** How is the  $n$  value of the  $d$  sublevel of a transition element related to the period number of the element?

**23.2** Write the general electron configuration of a transition element (a) in Period 5; (b) in Period 6.

**23.3** (a) What is the general rule concerning the order in which electrons are removed from a transition metal atom to form an ion? Give an example from Group 5B(5). (b) Name two types of measurements used to study electron configurations of ions.

**23.4** What is the maximum number of unpaired  $d$  electrons that an atom or ion can possess? Give an example of an atom and an ion that have this number.

**23.5** How does the variation in atomic size across a transition series contrast with the change across the main-group elements of the same period? Why?

**23.6** (a) What is the lanthanide contraction? (b) How does it affect atomic size down a group of transition elements? (c) How does it influence the densities of the Period 6 transition elements?

**23.7** (a) What is the range in electronegativity across the first ( $3d$ ) transition series? (b) What is the range across Period 4 of the main-group elements? (c) Explain the difference.

**23.8** (a) Explain the major difference between the number of oxidation states of most transition elements and that of most main-group elements. (b) Why is the +2 oxidation state so common among transition elements? (c) What is valence-state electronegativity? Is the electronegativity of Cr different in  $\text{CrO}$ ,  $\text{Cr}_2\text{O}_3$ , and  $\text{CrO}_3$ ? Explain.

**23.9** (a) What behavior distinguishes paramagnetic and diamagnetic substances? (b) Why are paramagnetic ions common among transition elements but not main-group elements? (c) Why are colored solutions of metal ions common among transition elements but not main-group elements?

#### Skill-Building Exercises (grouped in similar pairs)

**23.10** Using the periodic table to locate each element, write the electron configuration of (a) V; (b) Y; (c) Hg.

**23.11** Using the periodic table to locate each element, write the electron configuration of (a) Ru; (b) Cu; (c) Ni.

**23.12** Using the periodic table to locate each element, write the electron configuration of (a) Os; (b) Co; (c) Ag.

**23.13** Using the periodic table to locate each element, write the electron configuration of (a) Zn; (b) Mn; (c) Re.

**23.14** Give the electron configuration and the number of unpaired electrons for (a)  $\text{Sc}^{3+}$ ; (b)  $\text{Cu}^{2+}$ ; (c)  $\text{Fe}^{3+}$ ; (d)  $\text{Nb}^{3+}$ .

**23.15** Give the electron configuration and the number of unpaired electrons for (a)  $\text{Cr}^{3+}$ ; (b)  $\text{Ti}^{4+}$ ; (c)  $\text{Co}^{3+}$ ; (d)  $\text{Ta}^{2+}$ .

**23.16** What is the highest oxidation state for (a) Ta; (b) Zr; (c) Mn?

**23.17** What is the highest oxidation state for (a) Nb; (b) Y; (c) Tc?

**23.18** Which transition metals have a maximum O.N. of +6?

**23.19** Which transition metals have a maximum O.N. of +4?

**23.20** In which compound does Cr exhibit greater metallic behavior,  $\text{CrF}_2$  or  $\text{CrF}_6$ ? Explain.

**23.21**  $\text{VF}_5$  is a liquid that boils at  $48^\circ\text{C}$ , whereas  $\text{VF}_3$  is a solid that melts above  $800^\circ\text{C}$ . Explain this difference in properties.

**23.22** Is it more difficult to oxidize Cr or Mo? Explain.

**23.23** Is  $\text{MnO}_4^-$  or  $\text{ReO}_4^-$  a stronger oxidizing agent? Explain.

**23.24** Which oxide,  $\text{CrO}_3$  or  $\text{CrO}$ , is more acidic in water? Why?

**23.25** Which oxide,  $\text{Mn}_2\text{O}_3$  or  $\text{Mn}_2\text{O}_7$ , is more basic in water? Why?

#### Problems in Context

**23.26** The green patina of Cu-alloy roofs results from corrosion in the presence of  $\text{O}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ , and sulfur compounds. The other members of Group 1B(11), Ag and Au, do not form a patina. Corrosion of Cu and Ag in the presence of sulfur compounds leads to a black tarnish, but Au does not tarnish. This pattern is different from that in Group 1A(1), where ease of oxidation *increases* down the group. Explain these different group patterns.

### The Inner Transition Elements

(Sample Problem 23.2)

#### Concept Review Questions

**23.27** What atomic property of the lanthanides leads to their remarkably similar chemical properties?

**23.28** (a) What is the maximum number of unpaired electrons in a lanthanide ion? (b) How does this number relate to occupancy of the  $4f$  subshell?

**23.29** Which of the actinides are radioactive?

#### Skill-Building Exercises (grouped in similar pairs)

**23.30** Give the electron configuration of (a) La; (b)  $\text{Ce}^{3+}$ ; (c) Es; (d)  $\text{U}^{4+}$ .

**23.31** Give the electron configuration of (a) Pm; (b)  $\text{Lu}^{3+}$ ; (c) Th; (d)  $\text{Fm}^{3+}$ .

**23.32** Only a few lanthanides show an oxidation state other than +3. Two of these, europium (Eu) and terbium (Tb), are found near the middle of the series, and their unusual oxidation states can be associated with a half-filled  $f$  subshell. (a) Write the electron configurations of  $\text{Eu}^{2+}$ ,  $\text{Eu}^{3+}$ , and  $\text{Eu}^{4+}$ . Why is  $\text{Eu}^{2+}$  a common ion,

whereas  $\text{Eu}^{4+}$  is unknown? (b) Write the electron configurations of  $\text{Tb}^{2+}$ ,  $\text{Tb}^{3+}$ , and  $\text{Tb}^{4+}$ . Would you expect Tb to show a +2 or a +4 oxidation state? Explain.

**23.33** Cerium (Ce) and ytterbium (Yb) exhibit some oxidation states in addition to +3. (a) Write the electron configurations of  $\text{Ce}^{2+}$ ,  $\text{Ce}^{3+}$ , and  $\text{Ce}^{4+}$ . (b) Write the electron configurations of  $\text{Yb}^{2+}$ ,  $\text{Yb}^{3+}$ , and  $\text{Yb}^{4+}$ . (c) In addition to the 3+ ions, the ions  $\text{Ce}^{4+}$  and  $\text{Yb}^{2+}$  are stable. Suggest a reason for this stability.

### Problems in Context

**23.34** Which lanthanide has the maximum number of unpaired electrons in both its atom and its 3+ ion? Give the number of unpaired electrons in the atom and in the ion.

### Coordination Compounds

(Sample Problems 23.3 to 23.5)

### Concept Review Questions

**23.35** Describe the makeup of a complex ion, including the nature of the ligands and their interaction with the central metal ion. Explain how a complex ion can be positive or negative and how it occurs as part of a neutral coordination compound.

**23.36** What electronic feature must a donor atom of a ligand have?

**23.37** What is the coordination number of a metal ion in a complex ion? How does it differ from the oxidation number?

**23.38** What structural feature is characteristic of a chelate?

**23.39** What geometries are associated with the coordination numbers 2, 4, and 6?

**23.40** What are the coordination numbers of cobalt(III), platinum(II), and platinum(IV) in complexes?

**23.41** How is a complex ion a Lewis adduct?

**23.42** What does the ending *-ate* in the name of a complex ion signify?

**23.43** In what order are the metal ion and ligands identified in the name of a complex ion?

**23.44** Is a linkage isomer a type of constitutional isomer or stereoisomer? Explain.

### Skill-Building Exercises (grouped in similar pairs)

**23.45** Give systematic names for the following formulas:

(a)  $[\text{Ni}(\text{H}_2\text{O})_6]\text{Cl}_2$  (b)  $[\text{Cr}(\text{en})_3](\text{ClO}_4)_3$  (c)  $\text{K}_4[\text{Mn}(\text{CN})_6]$

**23.46** Give systematic names for the following formulas:

(a)  $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)_2]\text{Cl}$  (b)  $[\text{Cr}(\text{NH}_3)_6][\text{Cr}(\text{CN})_6]$

(c)  $\text{K}_2[\text{CuCl}_4]$

**23.47** What are the charge and coordination number of the central metal ion(s) in each compound in Problem 23.45?

**23.48** What are the charge and coordination number of the central metal ion(s) in each compound in Problem 23.46?

**23.49** Give systematic names for the following formulas:

(a)  $\text{K}[\text{Ag}(\text{CN})_2]$  (b)  $\text{Na}_2[\text{CdCl}_4]$  (c)  $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Br}]\text{Br}_2$

**23.50** Give systematic names for the following formulas:

(a)  $\text{K}[\text{Pt}(\text{NH}_3)\text{Cl}_5]$  (b)  $[\text{Cu}(\text{en})(\text{NH}_3)_2][\text{Co}(\text{en})\text{Cl}_4]$

(c)  $[\text{Pt}(\text{en})_2\text{Br}_2](\text{ClO}_4)_2$

**23.51** What are the charge and coordination number of the central metal ion(s) in each compound in Problem 23.49?

**23.52** What are the charge and coordination number of the central metal ion(s) in each compound in Problem 23.50?

**23.53** Give formulas corresponding to the following names:

- (a) Tetraamminezinc sulfate  
(b) Pentaamminechlorochromium(III) chloride  
(c) Sodium bis(thiosulfato)argentate(I)

**23.54** Give formulas corresponding to the following names:

- (a) Dibromobis(ethylenediamine)cobalt(III) sulfate  
(b) Hexaamminechromium(III) tetrachlorocuprate(II)  
(c) Potassium hexacyanoferrate(II)

**23.55** What is the coordination number of the metal ion and the number of individual ions per formula unit in each of the compounds in Problem 23.53?

**23.56** What is the coordination number of the metal ion and the number of individual ions per formula unit in each of the compounds in Problem 23.54?

**23.57** Give formulas corresponding to the following names:

- (a) Hexaaquachromium(III) sulfate  
(b) Barium tetrabromoferrate(III)  
(c) Bis(ethylenediamine)platinum(II) carbonate

**23.58** Give formulas corresponding to the following names:

- (a) Potassium tris(oxalato)chromate(III)  
(b) Tris(ethylenediamine)cobalt(III) pentacyanoiodomanganate(II)  
(c) Diamminediaquabromochloroaluminum nitrate

**23.59** Give the coordination number of the metal ion and the number of ions per formula unit in each compound in Problem 23.57.

**23.60** Give the coordination number of the metal ion and the number of ions per formula unit in each compound in Problem 23.58.

**23.61** Which of these ligands can participate in linkage isomerism: (a)  $\text{NO}_2^-$ ; (b)  $\text{SO}_2$ ; (c)  $\text{NO}_3^-$ ? Explain with Lewis structures.

**23.62** Which of these ligands can participate in linkage isomerism: (a)  $\text{SCN}^-$ ; (b)  $\text{S}_2\text{O}_3^{2-}$  (thiosulfate); (c)  $\text{HS}^-$ ? Explain with Lewis structures.

**23.63** For any of the following that can exist as isomers, state the type of isomerism and draw the structures:

(a)  $[\text{Pt}(\text{CH}_3\text{NH}_2)_2\text{Br}_2]$  (b)  $[\text{Pt}(\text{NH}_3)_2\text{FCl}]$  (c)  $[\text{Pt}(\text{H}_2\text{O})(\text{NH}_3)\text{FCl}]$

**23.64** For any of the following that can exist as isomers, state the type of isomerism and draw the structures:

(a)  $[\text{Zn}(\text{en})\text{F}_2]$  (b)  $[\text{Zn}(\text{H}_2\text{O})(\text{NH}_3)\text{FCl}]$  (c)  $[\text{Pd}(\text{CN})_2(\text{OH})_2]^{2-}$

**23.65** For any of the following that can exist as isomers, state the type of isomerism and draw the structures:

(a)  $[\text{PtCl}_2\text{Br}_2]^{2-}$  (b)  $[\text{Cr}(\text{NH}_3)_5(\text{NO}_2)]^{2+}$  (c)  $[\text{Pt}(\text{NH}_3)_4\text{I}_2]^{2+}$

**23.66** For any of the following that can exist as isomers, state the type of isomerism and draw the structures:

(a)  $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Br}_2$  (b)  $[\text{Pt}(\text{CH}_3\text{NH}_2)_3\text{Cl}]\text{Br}$

(c)  $[\text{Fe}(\text{H}_2\text{O})_4(\text{NH}_3)_2]^{2+}$

### Problems in Context

**23.67** Chromium(III), like cobalt(III), has a coordination number of 6 in many of its complex ions. Before Alfred Werner, in the 1890s, established the idea of a complex ion, coordination compounds had traditional formulas. Compounds are known that have the traditional formula  $\text{CrCl}_3 \cdot n\text{NH}_3$ , where  $n = 3$  to 6. Which of

these compounds has an electrical conductivity in aqueous solution similar to that of an equimolar NaCl solution?

**23.68** When  $\text{MCl}_4(\text{NH}_3)_2$  is dissolved in water and treated with  $\text{AgNO}_3$ , 2 mol of  $\text{AgCl}$  precipitates immediately for each mole of  $\text{MCl}_4(\text{NH}_3)_2$ . Give the coordination number of M in the complex.

**23.69** Palladium, like its group neighbor platinum, forms four-coordinate Pd(II) and six-coordinate Pd(IV) complexes. Write formulas for the complexes with these compositions:

(a)  $\text{PdK}(\text{NH}_3)\text{Cl}_3$  (b)  $\text{PdCl}_2(\text{NH}_3)_2$  (c)  $\text{PdK}_2\text{Cl}_6$  (d)  $\text{Pd}(\text{NH}_3)_4\text{Cl}_4$

### Theoretical Basis for the Bonding and Properties of Complexes

(Sample Problems 23.6 and 23.7)

#### Concept Review Questions

**23.70** (a) What is a coordinate covalent bond?  
(b) Is such a bond involved when  $\text{FeCl}_3$  dissolves in water? Explain.  
(c) Is such a bond involved when  $\text{HCl}$  gas dissolves in water? Explain.

**23.71** According to valence bond theory, what set of orbitals is used by a Period 4 metal ion in forming (a) a square planar complex; (b) a tetrahedral complex?

**23.72** A metal ion uses  $d^2sp^3$  orbitals when forming a complex. What is its coordination number and the shape of the complex?

**23.73** A complex in solution absorbs green light. What is the color of the solution?

**23.74** In terms of the theory of color absorption, explain two ways that a solution can be blue.

**23.75** (a) What is the crystal field splitting energy ( $\Delta$ )?  
(b) How does it arise for an octahedral field of ligands?  
(c) How is it different for a tetrahedral field of ligands?

**23.76** What is the distinction between a weak-field ligand and a strong-field ligand? Give an example of each.

**23.77** Is a complex with the same number of unpaired electrons as the free gaseous metal ion termed high spin or low spin?

**23.78** How do the relative magnitudes of  $E_{\text{pairing}}$  and  $\Delta$  affect the paramagnetism of a complex?

**23.79** Why are there both high-spin and low-spin octahedral complexes but only high-spin tetrahedral complexes?

#### Skill-Building Exercises (grouped in similar pairs)

**23.80** Give the number of  $d$  electrons ( $n$  of  $d^n$ ) for the central metal ion in (a)  $[\text{TiCl}_6]^{2-}$ ; (b)  $\text{K}[\text{AuCl}_4]$ ; (c)  $[\text{RhCl}_6]^{3-}$ .

**23.81** Give the number of  $d$  electrons ( $n$  of  $d^n$ ) for the central metal ion in (a)  $[\text{Cr}(\text{H}_2\text{O})_6](\text{ClO}_3)_2$ ; (b)  $[\text{Mn}(\text{CN})_6]^{2-}$ ; (c)  $[\text{Ru}(\text{NO})(\text{en})_2\text{Cl}]\text{Br}$ .

**23.82** How many  $d$  electrons ( $n$  of  $d^n$ ) are in the central metal ion in (a)  $\text{Ca}[\text{IrF}_6]$ ; (b)  $[\text{HgI}_4]^{2-}$ ; (c)  $[\text{Co}(\text{EDTA})]^{2-}$ ?

**23.83** How many  $d$  electrons ( $n$  of  $d^n$ ) are in the central metal ion in (a)  $[\text{Ru}(\text{NH}_3)_5\text{Cl}]\text{SO}_4$ ; (b)  $\text{Na}_2[\text{Os}(\text{CN})_6]$ ; (c)  $[\text{Co}(\text{NH}_3)_4\text{CO}_3]\text{I}$ ?

**23.84** Sketch the orientation of the orbitals relative to the ligands in an octahedral complex to explain the splitting and the relative energies of the  $d_{xy}$  and the  $d_{x^2-y^2}$  orbitals.

**23.85** The two  $e_g$  orbitals are identical in energy in an octahedral complex but have different energies in a square planar complex, with the  $d_z^2$  orbital being much lower in energy than the  $d_{x^2-y^2}$ . Explain with orbital sketches.

**23.86** Which of these ions *cannot* form both high- and low-spin octahedral complexes: (a)  $\text{Ti}^{3+}$ ; (b)  $\text{Co}^{2+}$ ; (c)  $\text{Fe}^{2+}$ ; (d)  $\text{Cu}^{2+}$ ?

**23.87** Which of these ions *cannot* form both high- and low-spin octahedral complexes: (a)  $\text{Mn}^{3+}$ ; (b)  $\text{Nb}^{3+}$ ; (c)  $\text{Ru}^{3+}$ ; (d)  $\text{Ni}^{2+}$ ?

**23.88** Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that  $\text{H}_2\text{O}$  is a weak-field ligand):

(a)  $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$  (b)  $[\text{Cu}(\text{H}_2\text{O})_4]^{2+}$  (c)  $[\text{FeF}_6]^{3-}$

**23.89** Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that  $\text{H}_2\text{O}$  is a weak-field ligand):

(a)  $[\text{Cr}(\text{CN})_6]^{3-}$  (b)  $[\text{Rh}(\text{CO})_6]^{3+}$  (c)  $[\text{Co}(\text{OH})_6]^{4-}$

**23.90** Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that  $\text{H}_2\text{O}$  is a weak-field ligand):

(a)  $[\text{MoCl}_6]^{3-}$  (b)  $[\text{Ni}(\text{H}_2\text{O})_6]^{2+}$  (c)  $[\text{Ni}(\text{CN})_4]^{2-}$

**23.91** Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that  $\text{H}_2\text{O}$  is a weak-field ligand):

(a)  $[\text{Fe}(\text{C}_2\text{O}_4)_3]^{3-}$  ( $\text{C}_2\text{O}_4^{2-}$  creates a weaker field than  $\text{H}_2\text{O}$  does.)  
(b)  $[\text{Co}(\text{CN})_6]^{4-}$  (c)  $[\text{MnCl}_6]^{4-}$

**23.92** Rank the following in order of *increasing*  $\Delta$  and energy of light absorbed:  $[\text{Cr}(\text{NH}_3)_6]^{3+}$ ,  $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$ ,  $[\text{Cr}(\text{NO}_2)_6]^{3-}$ .

**23.93** Rank the following in order of *decreasing*  $\Delta$  and energy of light absorbed:  $[\text{Cr}(\text{en})_3]^{3+}$ ,  $[\text{Cr}(\text{CN})_6]^{3-}$ ,  $[\text{CrCl}_6]^{3-}$ .

**23.94** A complex ion,  $[\text{ML}_6]^{2+}$ , is violet. The same metal forms a complex with another ligand, Q, that creates a weaker field. What color might  $[\text{MQ}_6]^{2+}$  be expected to show? Explain.

**23.95** The complex ion  $[\text{Cr}(\text{H}_2\text{O})_6]^{2+}$  is violet. Another  $\text{CrL}_6$  complex is green. Can ligand L be  $\text{CN}^-$ ? Can it be  $\text{Cl}^-$ ? Explain.

#### Problems in Context

**23.96** Octahedral  $[\text{Ni}(\text{NH}_3)_6]^{2+}$  is paramagnetic, whereas planar  $[\text{Pt}(\text{NH}_3)_4]^{2+}$  is diamagnetic, even though both metal ions are  $d^8$  species. Explain.

**23.97** The hexaqua complex  $[\text{Ni}(\text{H}_2\text{O})_6]^{2+}$  is green, whereas the hexaammonia complex  $[\text{Ni}(\text{NH}_3)_6]^{2+}$  is violet. Explain.

**23.98** Three of the complex ions that are formed by  $\text{Co}^{3+}$  are  $[\text{Co}(\text{H}_2\text{O})_6]^{3+}$ ,  $[\text{Co}(\text{NH}_3)_6]^{3+}$ , and  $[\text{CoF}_6]^{3-}$ . These ions have the observed colors (listed in arbitrary order) yellow-orange, green, and blue. Match each complex with its color. Explain.

#### Comprehensive Problems

**23.99** When neptunium (Np) and plutonium (Pu) were discovered, the periodic table did not include the actinides, so these elements were placed in Groups 7B(7) and 8B(8). When americium (Am) and curium (Cm) were synthesized, they were placed in Groups 8B(9) and 8B(10). However, during chemical isolation procedures, Glenn Seaborg and his colleagues, who had synthesized these elements, could not find their compounds among other compounds of members of the same groups, which led Seaborg to suggest they were part of a new inner transition series.

(a) How do the electron configurations of these elements support Seaborg's suggestion?

(b) The highest fluorides of Np and Pu are hexafluorides, and the highest fluoride of uranium is also the hexafluoride. How does

this chemical evidence support the placement of Np and Pu as *inner* transition elements rather than transition elements?

**23.100** How many different formulas are there for octahedral complexes with a metal M and four ligands A, B, C, and D? Give the number of isomers for each formula and describe the isomers.

**23.101** At one time, it was common to write the formula for copper(I) chloride as  $\text{Cu}_2\text{Cl}_2$ , instead of  $\text{CuCl}$ , analogously to  $\text{Hg}_2\text{Cl}_2$  for mercury(I) chloride. Use electron configurations to explain why  $\text{Hg}_2\text{Cl}_2$  and  $\text{CuCl}$  are both correct.

**23.102** For the compound  $[\text{Co}(\text{en})_2\text{Cl}_2]\text{Cl}$ , give:

- The coordination number of the metal ion
- The oxidation number of the central metal ion
- The number of individual ions per formula unit
- The moles of  $\text{AgCl}$  that precipitate when 1 mol of compound is dissolved in water and treated with  $\text{AgNO}_3$

**23.103** Hexafluorocobaltate(III) ion is a high-spin complex. Draw the energy diagram for the splitting of its *d* orbitals.

**23.104** A salt of each of the ions in Table 23.3 is dissolved in water. A Pt electrode is immersed in each solution and connected to a 0.38-V battery. All of the electrolytic cells are run for the same amount of time with the same current.

- In which cell(s) will a metal plate out? Explain.
- Which cell will plate out the least mass of metal? Explain.

**23.105** Criticize and correct the following statement: strong-field ligands always give rise to low-spin complexes.

**23.106** Some octahedral complexes have distorted shapes. In some, two metal-ligand bonds that are  $180^\circ$  apart are shorter than the other four. In  $[\text{Cu}(\text{NH}_3)_6]^{2+}$ , for example, two Cu–N bonds are 207 pm long, and the other four are 262 pm long. (a) Calculate the longest distance between two N atoms in this complex. (b) Calculate the shortest distance between two N atoms.

**23.107** In many species, a transition metal has an unusually high or low oxidation state. Write balanced equations for the following and find the oxidation state of the transition metal in the product:

- Iron(III) ion reacts with hypochlorite ion in basic solution to form ferrate ion ( $\text{FeO}_4^{2-}$ ),  $\text{Cl}^-$ , and water.
- Potassium hexacyanomanganate(II) reacts with K metal to form  $\text{K}_6[\text{Mn}(\text{CN})_6]$ .
- Heating sodium superoxide ( $\text{NaO}_2$ ) with  $\text{Co}_3\text{O}_4$  produces  $\text{Na}_4\text{CoO}_4$  and  $\text{O}_2$  gas.
- Vanadium(III) chloride reacts with Na metal under a CO atmosphere to produce  $\text{Na}[\text{V}(\text{CO})_6]$  and  $\text{NaCl}$ .
- Barium peroxide reacts with nickel(II) ions in basic solution to produce  $\text{BaNiO}_3$ .
- Bubbling CO through a basic solution of cobalt(II) ion produces  $[\text{Co}(\text{CO})_4]^-$ ,  $\text{CO}_3^{2-}$ , and water.
- Heating cesium tetrafluorocuprate(II) with  $\text{F}_2$  gas under pressure gives  $\text{Cs}_2\text{CuF}_6$ .
- Heating tantalum(V) chloride with Na metal produces  $\text{NaCl}$  and  $\text{Ta}_6\text{Cl}_{15}$ , in which half of the Ta is in the +2 state.
- Potassium tetracyanonickelate(II) reacts with hydrazine ( $\text{N}_2\text{H}_4$ ) in basic solution to form  $\text{K}_4[\text{Ni}_2(\text{CN})_6]$  and  $\text{N}_2$  gas.

**23.108** Draw a Lewis structure with lowest formal charges for  $\text{MnO}_4^-$ .

**23.109** The coordination compound  $[\text{Pt}(\text{NH}_3)_2(\text{SCN})_2]$  displays two types of isomerism. Name the types, and give names and structures for the six possible isomers.

**23.110** An octahedral complex with three different ligands (A, B, and C) can have formulas with three different ratios of the ligands:  $[\text{MA}_4\text{BC}]^{n+}$ , such as  $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Cl}]^{2+}$ ;  $[\text{MA}_3\text{B}_2\text{C}]^{n+}$ , such as  $[\text{Cr}(\text{H}_2\text{O})_3\text{Br}_2\text{Cl}]$ ;  $[\text{MA}_2\text{B}_2\text{C}_2]^{n+}$ , such as  $[\text{Cr}(\text{NH}_3)_2(\text{H}_2\text{O})_2\text{Br}_2]^+$ . For each example, give the name, state the type(s) of isomerism present, and draw all isomers.

**23.111** In  $[\text{Cr}(\text{NH}_3)_6]\text{Cl}_3$ , the  $[\text{Cr}(\text{NH}_3)_6]^{3+}$  ion absorbs visible light in the blue-violet range, and the compound is yellow-orange. In  $[\text{Cr}(\text{H}_2\text{O})_6]\text{Br}_3$ , the  $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$  ion absorbs visible light in the red range, and the compound is blue-gray. Explain these differences in light absorbed and compound color.

**23.112** The actinides Pa, U, and Np form a series of complex ions, such as the anion in the compound  $\text{Na}_3[\text{UF}_8]$ , in which the central metal ion has an unusual geometry and oxidation state. In the crystal structure, the complex ion can be pictured as resulting from interpenetration of simple cubic arrays of uranium and fluoride ions. (a) What is the coordination number of the metal ion in the complex ion? (b) What is the oxidation state of uranium in the compound? (c) Sketch the complex ion.

**23.113** Several coordination isomers, with both Co and Cr as 3+ ions, have the molecular formula  $\text{CoCrC}_6\text{H}_{18}\text{N}_{12}$ . (a) Give the name and formula of the isomer in which the Co complex ion has six  $\text{NH}_3$  groups. (b) Give the name and formula of the isomer in which the Co complex ion has one CN and five  $\text{NH}_3$  groups.

**23.114** Consider the square planar complex shown at right. Which of the structures A–F are geometric isomers of it?

**23.115** A shortcut to finding optical isomers is to see if the complex has a *plane of symmetry*—a plane passing through the metal atom such that every atom on one side of the plane is matched by an identical one at the same distance from the plane on the other side. Any planar complex has a plane of symmetry, since all atoms lie in one plane. Use this approach to determine whether these exist as optical isomers: (a)  $[\text{Zn}(\text{NH}_3)_2\text{Cl}_2]$  (tetrahedral); (b)  $[\text{Pt}(\text{en})_2]^{2+}$ ; (c) *trans*- $[\text{PtBr}_4\text{Cl}_2]^{2-}$ ; (d) *trans*- $[\text{Co}(\text{en})_2\text{F}_2]^+$ ; (e) *cis*- $[\text{Co}(\text{en})_2\text{F}_2]^+$ .

**23.116** Alfred Werner (see Problem 23.67) prepared two compounds by heating a solution of  $\text{PtCl}_2$  with triethyl phosphine,  $\text{P}(\text{C}_2\text{H}_5)_3$ , which is a ligand for Pt. Both compounds have, by mass, Pt, 38.8%; Cl, 14.1%; C, 28.7%; P, 12.4%; and H, 6.02%. Write formulas, structures, and systematic names for the two isomers.

**23.117** Two bidentate ligands used extensively in analytical chemistry are bipyridyl (bipy) and *ortho*-phenanthroline (*o*-phen):

Draw structures and discuss the possibility of isomers for

- (a)  $[\text{Pt}(\text{bipy})\text{Cl}_2]$       (b)  $[\text{Fe}(o\text{-phen})_3]^{3+}$   
 (c)  $[\text{Co}(\text{bipy})_2\text{F}_2]^+$       (d)  $[\text{Co}(o\text{-phen})(\text{NH}_3)_3\text{Cl}]^{2+}$

**23.118** The effect of entropy on reactions is demonstrated by the stabilities of certain complexes. (a) Based on the numbers of reactant and product particles, predict which of the following reactions will be favored in terms of  $\Delta S_{\text{rxn}}^\circ$ :

(b) Given that the Cu–N bond strength is approximately the same in both complexes, which complex will be more stable with respect to ligand exchange in water? Explain.

**23.119** You know the following about a coordination compound:

- (1) The partial empirical formula is  $\text{KM}(\text{CrO}_4)\text{Cl}_2(\text{NH}_3)_4$ .
- (2) It has A (red) and B (blue) crystal forms.
- (3) When 1.0 mol of A or B reacts with 1.0 mol of  $\text{AgNO}_3$ , 0.50 mol of a red precipitate forms immediately.
- (4) After the reaction in (3), 1.0 mol of A reacts very slowly with 1.0 mol of silver oxalate ( $\text{Ag}_2\text{C}_2\text{O}_4$ ) to form 2.0 mol of a white precipitate. (Oxalate can displace other ligands.)
- (5) After the reaction in (3), 1.0 mol of B does not react further with 1.0 mol of  $\text{AgNO}_3$ .

From this information, determine the following:

- (a) The coordination number of M
- (b) The group(s) bonded to M ionically and covalently
- (c) The stereochemistry of the red and blue forms

**23.120** The extent of crystal field splitting is often determined from spectra. (a) Given the wavelength ( $\lambda$ ) of maximum absorption, find the crystal field splitting energy ( $\Delta$ ), in kJ/mol, for each of the following complex ions:

Ion	$\lambda$ (nm)	Ion	$\lambda$ (nm)
$[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$	562	$[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$	966
$[\text{Cr}(\text{CN})_6]^{3-}$	381	$[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$	730
$[\text{CrCl}_6]^{3-}$	735	$[\text{Co}(\text{NH}_3)_6]^{3+}$	405
$[\text{Cr}(\text{NH}_3)_6]^{3+}$	462	$[\text{Rh}(\text{NH}_3)_6]^{3+}$	295
$[\text{Ir}(\text{NH}_3)_6]^{3+}$	244		

- (b) Write a spectrochemical series for the ligands in the Cr complexes.
- (c) Use the Fe data to state how oxidation state affects  $\Delta$ .
- (d) Use the Co, Rh, and Ir data to state how period number affects  $\Delta$ .

**23.121** Ionic liquids have many applications in engineering and materials science. The dissolution of the metavanadate ion in chloroaluminate ionic liquids has been studied:

- (a) What is the oxidation number of V and Al in each ion?
- (b) In reactions of  $\text{V}_2\text{O}_5$  with HCl, acid concentration affects the product. At low acid concentration,  $\text{VO}_2\text{Cl}_2^-$  and  $\text{VO}_3^-$  form:

At high acid concentration,  $\text{VOCl}_3$  forms:

Balance each equation, and state which, if either, is a redox process.

- (c) What mass of  $\text{VO}_2\text{Cl}_2^-$  or  $\text{VOCl}_3$  can form from 12.5 g of  $\text{V}_2\text{O}_5$  and the appropriate concentration of acid?

**23.122** The orbital occupancies for the *d* orbitals of several complex ions are diagrammed below.

- (a) Which diagram corresponds to the orbital occupancy of the cobalt ion in  $[\text{Co}(\text{CN})_6]^{3-}$ ?
- (b) If diagram D depicts the orbital occupancy of the cobalt ion in  $[\text{CoF}_6]^n$ , what is the value of *n*?
- (c)  $[\text{NiCl}_4]^{2-}$  is paramagnetic and  $[\text{Ni}(\text{CN})_4]^{2-}$  is diamagnetic. Which diagrams correspond to the orbital occupancies of the nickel ions in these species?
- (d) Diagram C shows the orbital occupancy of  $\text{V}^{2+}$  in the octahedral complex  $\text{VL}_6$ . Can you determine whether L is a strong- or weak-field ligand? Explain.

- › discovery of the atomic nucleus (Section 2.4)
- › half-life and first-order reaction rate (Section 16.4)
- › protons, neutrons, mass number, and the  ${}^A_ZX$  notation (Section 2.5)

Up to this point in the text, we have focused on the atom's electrons, treating the nucleus as their electrostatic anchor and examining the effect of its positive charge on atomic properties and, ultimately, chemical behavior. In this chapter, for the most part, we ignore the surrounding electrons and focus on the atom's tiny, dense core, which is held together by the strongest force in the universe. Scientists studying the structure and behavior of the nucleus encounter great mystery and wonder but also uncover a great number of applications. To cite just one example, modern medicine relies, to an ever-increasing extent, on diagnoses based on the emission of radiation from unstable nuclei. In fact, more than one in four hospital admissions now involve imaging tests such as stress tests, bone scans, and PET scans (*see photo*) that utilize *radioisotopes*.

But society is ambivalent about some applications of nuclear research. The promise of abundant energy and effective treatments for diseases is offset by the threat of nuclear waste contamination, reactor accidents, and unimaginable destruction from nuclear war or terrorism. Can the power of the nucleus be harnessed for our benefit, or are the risks too great? In this chapter, you'll learn the principles that can help you consider this vital question.

**IN THIS CHAPTER . . .** We survey the field of nuclear chemistry, examining radioactive nuclei and their decay processes, especially the effects and applications of radioactivity and the interconversion of matter and energy.

- › We investigate nuclear stability to determine why some nuclei are stable and others undergo radioactive decay.
- › We learn how radioactivity is detected and how the kinetics of decay is applied.
- › We see how nuclei synthesized in particle accelerators have extended the periodic table.
- › We consider the effects of radioactive emissions on matter, especially living tissue, and focus on some major uses of radioisotopes in science, technology, and medicine.
- › We discuss the mass difference that arises when a nucleus forms from its subatomic particles and the energy that is equivalent to this difference.
- › We explore current and future attempts to harness the energy released when heavy nuclei split or lighter ones fuse.
- › We look at the nuclear processes in stars that continually create chemical elements.

## 24.1 RADIOACTIVE DECAY AND NUCLEAR STABILITY

A stable nucleus remains intact indefinitely, but *the great majority of nuclei are unstable*. An unstable nucleus exhibits **radioactivity**, the spontaneous disintegration of a nucleus by the emission of radiation. In Section 24.2, you'll see that each type of unstable nucleus has its own characteristic *rate* of radioactive decay. In this section, we cover important terms and notation for nuclei, discuss some key events in the discovery of radioactivity, define the types of emission, describe various modes of radioactive decay, and see how to predict which occurs for a given nucleus. Let's begin, however, with a brief comparison of chemical change and nuclear change.

Table 24.1

Comparison of Chemical and Nuclear Reactions

Chemical Reactions	Nuclear Reactions
1. One substance is converted into another, but atoms never change identity.	1. Atoms of one element typically are converted into atoms of another element.
2. Electrons in orbitals are involved as bonds break and form; nuclear particles do not take part.	2. Protons, neutrons, and other nuclear particles are involved; electrons in orbitals take part much less often.
3. Reactions are accompanied by relatively small changes in energy and no measurable changes in mass.	3. Reactions are accompanied by relatively large changes in energy and measurable changes in mass.
4. Reaction rates are influenced by temperature, concentration, catalysts, and the compound in which an element occurs.	4. Reaction rates depend on number of nuclei, but are not affected by temperature, catalysts, or, except on rare occasions, the compound in which an element occurs.

## Comparing Chemical and Nuclear Change

The changes that occur in atomic nuclei differ strikingly from chemical changes (Table 24.1). In chemical reactions, electrons are shared or transferred to form *compounds*, while nuclei remain unchanged. In nuclear reactions, the roles are reversed: electrons take part much less often, while nuclei undergo changes that, in nearly every case, form different *elements*. Nuclear reactions are often accompanied by energy changes a million times greater than those for chemical reactions, energy changes so large that the accompanying changes in mass *are* detectable. Moreover, nuclear reaction yields and rates are *not* subject to the effects of pressure, temperature, and catalysis that influence chemical reactions.

## The Components of the Nucleus: Terms and Notation

Recall from Chapter 2 that the nucleus contains essentially all the atom's mass but accounts for only about  $10^{-5}$  times its radius and, therefore,  $10^{-15}$  times its volume, making the nucleus incredibly dense: about  $10^{14}$  g/mL. ◀ *Protons* and *neutrons*, the elementary particles that make up the nucleus, are called **nucleons**. A **nuclide** is a nucleus with a particular composition, that is, with specific numbers of the two types of nucleons. Most elements occur in nature as a mixture of **isotopes**, atoms with the characteristic number of protons of the element but different numbers of neutrons. For example, oxygen has three naturally occurring isotopes, and carbon also has three, but tin has ten, the most of any element. *Thus, each isotope of an element has a different nuclide.*

The relative mass and charge of a particle—elementary particle or nuclide—are described by the notation  ${}^A_ZX$  where *X* is the *symbol* for the particle, *A* is the *mass number*, or the total number of nucleons making up the particle, and *Z* is the *charge* of the particle; for nuclei, *A* is the *sum of protons and neutrons* and *Z* is the *number of protons* (atomic number). With this notation, the three subatomic elementary particles are represented as follows:

(A proton is also sometimes represented as  ${}^1_1\text{H}^+$ .) The number of neutrons (*N*) in a nucleus is the mass number (*A*) minus the atomic number (*Z*):  $N = A - Z$ . For example, the two naturally occurring stable isotopes of chlorine are

Nuclides can also be designated with the element name followed by the mass number, for example, chlorine-35 and chlorine-37. In naturally occurring samples of an element or its compounds, *the isotopes of the element are present in specific proportions* that vary only very slightly (see Chapter 2). Thus, in a sample of sodium chloride (or any Cl-containing substance), 75.77% of the Cl atoms are chlorine-35 and the remaining 24.23% are chlorine-37.

To understand this chapter, you need to be comfortable with nuclear notations, so please take a moment to review Sample Problem 2.4 and Problems 2.39 to 2.46.

### Big Atom with a Tiny, Massive Core

If you could strip the electrons from the atoms in an object and compress the nuclei together, the object would lose only a fraction of a percent of its mass, but it would shrink to 0.0000000000001% ( $10^{-13}$ %) of its volume!

## The Discovery of Radioactivity and the Types of Emissions

In 1896, the French physicist Antoine-Henri Becquerel accidentally discovered that uranium minerals emit a penetrating radiation that can expose a photographic plate. Becquerel also found that the radiation creates an electric discharge in air, thus providing a means for measuring its intensity.

**Curie and Rutherford: The Nature of Radioactivity and Element Identity** Based on Becquerel's discovery, in 1898, a young doctoral student named Marie Sklodowska Curie began a search for other minerals that behaved like uranium minerals. She found that thorium minerals also emit radiation and, most importantly, that *the intensity of the radiation is directly proportional to the concentration of the element in the mineral, not to the formula of the mineral or compound*. Curie named the emissions *radioactivity* and showed that they are *unaffected by temperature, pressure, or other physical and chemical conditions*.

After months of painstaking chemical work, Curie and her husband, physicist Pierre Curie, showed clear evidence of two new elements in pitchblende, the principal ore of uranium: polonium (Po;  $Z = 84$ ), the most metallic member of Group 6A(16), and radium (Ra;  $Z = 88$ ), the heaviest alkaline earth metal.

Then, focusing on obtaining a measurable amount of radium, Curie started with several tons of pitchblende residues from which the uranium had been extracted and worked arduously for four years to isolate 0.1 g of radium chloride, which she melted and electrolyzed to obtain pure metallic radium. Curie is the only person to have received two Nobel Prizes in science, one in physics for her research into radioactivity and the other in chemistry for her discoveries of polonium and radium.

During the next few years, Becquerel, the Curies, and Paul Villard in France and Ernest Rutherford and his coworkers in England studied the nature of radioactive emissions. A key finding was the observation of Rutherford and his colleague Frederick Soddy that elements other than radium were formed when radium decayed. In 1902, they proposed that radioactive emissions result in the change of one element into another. This explanation seemed like a return to alchemy and was met with disbelief and ridicule. We now know it to be true: *when a nuclide of one element decays, it emits radiation and usually changes into a nuclide of a different element*.

**Types of Radioactive Emissions** There are three natural types of radioactive emissions:

- **Alpha particles** (symbolized  $\alpha$ ,  ${}^4_2\alpha$ , or  ${}^4_2\text{He}^{2+}$ ) are identical to helium-4 nuclei.
- **Beta particles** (symbolized  $\beta$ ,  $\beta^-$ , or sometimes  ${}_{-1}^0\beta$ ) are high-speed electrons. (The emission of an electron from a nucleus may seem strange, but as you'll see shortly, it results from a nuclear reaction.)
- **Gamma rays** (symbolized  $\gamma$ , or sometimes  ${}^0_0\gamma$ ) are very high-energy photons.

Figure 24.1 illustrates the behavior of these emissions in an electric field: the positively charged  $\alpha$  particles curve to a small extent toward the negative plate, the negatively charged  $\beta$  particles curve to a greater extent toward the positive plate (because they have lower mass), and the uncharged  $\gamma$  rays are not affected by the electric field.

## Modes of Radioactive Decay; Balancing Nuclear Equations

*When a nuclide decays, it becomes a nuclide of lower energy, and the excess energy is carried off by the emitted radiation and the recoiling nucleus. The decaying, or reactant, nuclide is called the *parent*; the product nuclide is called the *daughter*. Nuclides can decay in several ways. As each of the major modes of decay is introduced (Table 24.2, next page), we'll show examples of that mode and apply the key principle used to balance nuclear reactions: *the total  $Z$  (charge, number of protons) and the total  $A$  (sum of protons and neutrons) of the reactants equal those of the products*:*

$$\begin{matrix} \text{Total } A \\ \text{Total } Z \end{matrix} \text{ Reactants} = \begin{matrix} \text{Total } A \\ \text{Total } Z \end{matrix} \text{ Products} \quad (24.1)$$

**Figure 24.1** How the three types of radioactive emissions behave in an electric field.

Table 24.2 Modes of Radioactive Decay\*

Mode	Emission	Decay Process	Change in		
			A	Z	N
$\alpha$ Decay	$\alpha$ ( ${}^4_2\text{He}^{2+}$ )	 <p style="text-align: center;"> <math>\alpha</math> expelled         </p>	-4	-2	-2
$\beta^-$ Decay <sup>†</sup>	$\beta^-$ ( ${}^0_{-1}\beta$ )	 <p style="text-align: center;">           nucleus with <math>xp^+</math> and <math>yn^0</math> → nucleus with <math>(x+1)p^+</math> and <math>(y-1)n^0</math>  <math>\beta^-</math> expelled         </p>	0	+1	-1
	Net:	 <p style="text-align: center;"> <math>{}^1_0n</math> in nucleus → <math>{}^1_1p</math> in nucleus + <math>{}^0_{-1}\beta</math> expelled         </p>			
Positron ( $\beta^+$ ) emission <sup>†</sup>	$\beta^+$ ( ${}^0_1\beta$ )	 <p style="text-align: center;">           nucleus with <math>xp^+</math> and <math>yn^0</math> → nucleus with <math>(x-1)p^+</math> and <math>(y+1)n^0</math>  <math>\beta^+</math> expelled         </p>	0	-1	+1
	Net:	 <p style="text-align: center;"> <math>{}^1_1p</math> in nucleus → <math>{}^1_0n</math> in nucleus + <math>{}^0_1\beta</math> expelled         </p>			
Electron ( $e^-$ ) capture (EC) <sup>†</sup>	x-ray	 <p style="text-align: center;">           nucleus with <math>xp^+</math> and <math>yn^0</math> → nucleus with <math>(x-1)p^+</math> and <math>(y+1)n^0</math> </p>	0	-1	+1
	Net:	 <p style="text-align: center;"> <math>{}^0_{-1}e</math> absorbed from low-energy orbital + <math>{}^1_1p</math> in nucleus → <math>{}^1_0n</math> in nucleus         </p>			
Gamma ( $\gamma$ ) emission	$\gamma$	 <p style="text-align: center;">           excited nucleus → stable nucleus + <math>\gamma</math> photon radiated         </p>	0	0	0

\*Nuclear chemists consider  $\beta^-$  decay, positron emission, and electron capture to be three decay modes of the more general process known as beta decay (see text).

<sup>†</sup>Neutrinos ( $\nu$ ) or antineutrinos ( $\bar{\nu}$ ) are also formed during the three modes of beta decay. Although we will not include them in other equations in the chapter, keep in mind that antineutrinos are always expelled during  $\beta^-$  decay, and neutrinos are expelled during  $\beta^+$  emission and  $e^-$  capture. The mass of a neutrino or antineutrino is estimated to be less than  $10^{-4}$  the mass of an electron.

1. **Alpha ( $\alpha$ ) decay** involves the loss of an  $\alpha$  particle from a nucleus. For each  $\alpha$  particle emitted by the parent, *A decreases by 4 and Z decreases by 2* in the daughter. Every element beyond bismuth (Bi;  $Z = 83$ ) is radioactive and exhibits  $\alpha$  decay, which is *the most common means for a heavy, unstable nucleus to become more stable*. For example, radium undergoes  $\alpha$  decay to yield radon (Rn;  $Z = 86$ ):

Note that the  $A$  value for Ra equals the sum of the  $A$  values for Rn and  $\alpha$  ( $226 = 222 + 4$ ), and that the  $Z$  value for Ra equals the sum of the  $Z$  values for Rn and  $\alpha$  ( $88 = 86 + 2$ ).

2. **Beta ( $\beta$ ) decay** is a general class of radioactive decay that encompasses three modes:  $\beta^-$  decay,  $\beta^+$  emission, and electron capture.

- **$\beta^-$  decay** (or *negatron emission*) occurs through the ejection of a  $\beta^-$  particle (high-speed electron) from the nucleus. This change does not involve expulsion of a  $\beta^-$  particle that was in the nucleus; rather, *a neutron is converted into a proton, which remains in the nucleus, and a  $\beta^-$  particle, which is expelled immediately*:

As always, the totals of the  $A$  and the  $Z$  values for reactant and products are equal. Radioactive nickel-63 becomes stable copper-63 through  $\beta^-$  decay:

Another example is the  $\beta^-$  decay of carbon-14, used in radiocarbon dating:

Note that  *$\beta^-$  decay results in a product nuclide with the same  $A$  but with  $Z$  one greater (one more proton) than in the reactant nuclide*. In other words, an atom of the element with the next *higher* atomic number is formed. Although equations in this chapter do not include it, a neutral particle called an antineutrino ( $\bar{\nu}$ ) is also emitted during  $\beta^-$  decay. The mass of the antineutrino is thought to be much less than  $10^{-4}$  times that of an electron.

- **Positron ( $\beta^+$ ) emission** is the emission of a  $\beta^+$  particle from the nucleus. A key idea of modern physics is that most fundamental particles have corresponding *antiparticles* with the same mass but opposite charge. The **positron** is the antiparticle of the electron. Positron emission occurs through a process in which *a proton in the nucleus is converted into a neutron and a positron, which is expelled*:

Also emitted during this process is a *neutrino* ( $\nu$ ), the antiparticle of the antineutrino. In terms of the effect on  $A$  and  $Z$ , *positron emission has the opposite effect of  $\beta^-$  decay: the daughter has the same  $A$  but  $Z$  is one less (one fewer proton) than for the parent*. Thus, an atom of the element with the next *lower* atomic number forms. Carbon-11, a synthetic radioisotope, decays to a stable boron isotope through  $\beta^+$  emission:

- **Electron ( $e^-$ ) capture (EC)** occurs when the nucleus draws in an electron from a low atomic energy level. The net effect is that *a proton is transformed into a neutron*:

(We use the symbol  $e^-$ , or  ${}_{-1}^0\text{e}$ , to distinguish an orbital electron from a beta particle  $\beta^-$ , or  ${}_{-1}^0\beta$ .) The orbital vacancy is quickly filled by an electron that moves down from a higher energy level, and that process continues through still higher energy levels, with x-ray photons and neutrinos carrying off the energy difference in each step. Radioactive iron becomes stable manganese through electron capture:

Even though the processes are different, *electron capture has the same net effect as positron emission:  $Z$  reduced by 1,  $A$  unchanged*.

**Changes in A and Z  
During Radioactive  
Decay**

Table 24.3

Mode of Decay	Change in	
	A	Z
$\alpha$ decay	-4	-2
$\beta^-$ decay	0	+1
$\beta^+$ decay	0	-1
Electron capture	0	-1
Gamma emission	0	0

3. **Gamma ( $\gamma$ ) emission** involves the radiation of high-energy  $\gamma$  photons (also called  $\gamma$  rays) from an excited nucleus. Just as an atom in an excited *electronic* state reduces its energy by emitting photons, usually in the UV and visible ranges (see Section 7.2), a nucleus in an excited state lowers its energy by emitting  $\gamma$  photons, which are of much higher energy (much shorter wavelength) than UV photons. Many nuclear processes leave the nucleus in an excited state, so  $\gamma$  emission accompanies many other (mostly  $\beta$ ) types of decay. Several  $\gamma$  photons of different energies can be emitted from an excited nucleus as it returns to the ground state. Some of Marie Curie's experiments involved the release of  $\gamma$  rays, as in the decay of polonium-215:

Gamma emission often accompanies  $\beta^-$  decay:

Because  $\gamma$  rays have no mass or charge,  $\gamma$  emission does not change A or Z. Two gamma rays are emitted when a particle and an antiparticle annihilate each other. In the medical technology known as *positron-emission tomography* (see Section 24.5), a positron and an electron annihilate each other (with all A and Z values shown):

Table 24.3 summarizes the changes in mass number and atomic number that result from the various modes of decay.

## SAMPLE PROBLEM 24.1

## Writing Equations for Nuclear Reactions

**Problem** Write balanced equations for the following nuclear reactions:

- Naturally occurring thorium-232 undergoes  $\alpha$  decay.
- Zirconium-86 undergoes electron capture.

**Plan** We first write a skeleton equation that includes the mass numbers, atomic numbers, and symbols of all the particles on the correct sides of the equation, showing the unknown product particle as  ${}_Z^AX$ . Then, because the total of mass numbers and the total of atomic numbers must be equal on the left and right sides, we solve for A and Z, and use Z to determine X from the periodic table.

**Solution** (a) Writing the skeleton equation, with the  $\alpha$  particle as a product:

Solving for A and Z and balancing the equation: For A,  $232 = A + 4$ , so  $A = 228$ . For Z,  $90 = Z + 2$ , so  $Z = 88$ . From the periodic table, we see that the element with  $Z = 88$  is radium (Ra). Thus, the balanced equation is

(b) Writing the skeleton equation, with the captured electron as a reactant:

Solving for A and Z and balancing the equation: For A,  $86 + 0 = A$ , so  $A = 86$ . For Z,  $40 + (-1) = Z$ , so  $Z = 39$ . The element with  $Z = 39$  is yttrium (Y), so we have

**Check** Always read across superscripts and then across subscripts, with the yield arrow as an equal sign, to check your arithmetic. In part (a), for example,  $232 = 228 + 4$ , and  $90 = 88 + 2$ .

## FOLLOW-UP PROBLEMS

*Brief Solutions for all Follow-up Problems appear at the end of the chapter.*

**24.1A** Write a balanced equation for the nuclear reaction in which fluorine-20 undergoes  $\beta^-$  decay.

**24.1B** Write a balanced equation for the reaction in which a nuclide undergoes  $\beta^+$  decay and changes to tellurium-124.

**SOME SIMILAR PROBLEMS** 24.8–24.15

 Student Hot Spot

## Nuclear Stability and the Mode of Decay

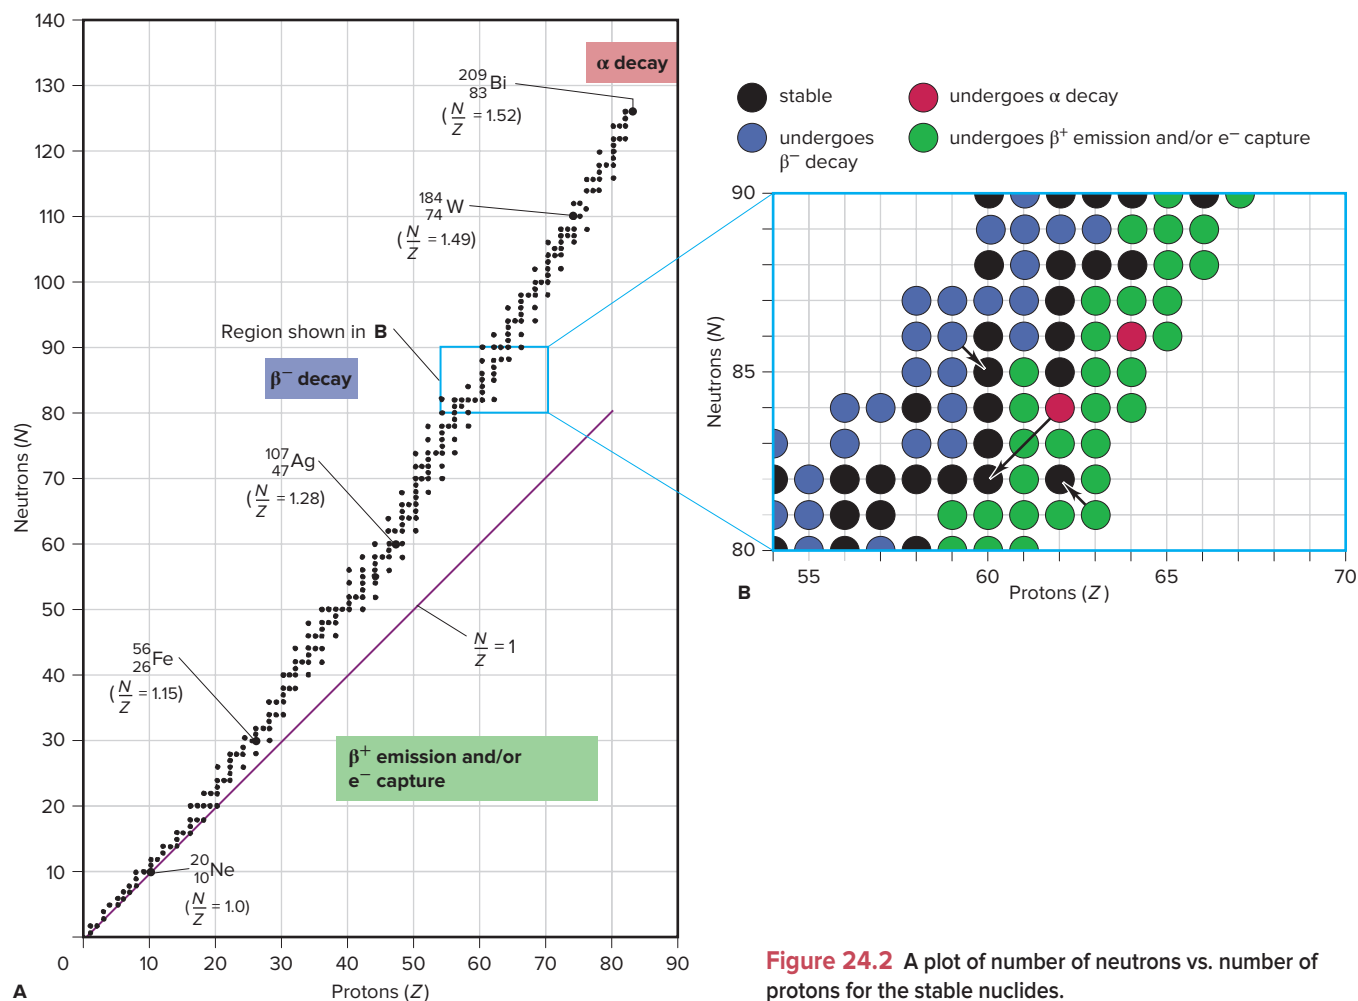

Can we predict how, and whether, an unstable nuclide will decay? Our knowledge of the nucleus is much less complete than that of the whole atom, but some patterns emerge by observing naturally occurring nuclides.

**The Band of Stability** Two key factors determine the stability of a nuclide:

1. The number of neutrons ( $N$ ), the number of protons ( $Z$ ), and their ratio ( $N/Z$ ), which we calculate from  $(A - Z)/Z$ . This factor relates primarily to nuclides that undergo one of the three modes of  $\beta$  decay.
2. The total mass of the nuclide, which mostly relates to nuclides that undergo  $\alpha$  decay.

A plot of number of neutrons vs. number of protons for all stable nuclides (Figure 24.2A) shows:

- The points form a narrow **band of stability** that gradually curves above the line for  $N = Z$  ( $N/Z = 1$ ).
- The only stable nuclides with  $N/Z < 1$  are  ${}^1_1\text{H}$  and  ${}^3_2\text{He}$ .
- Many lighter nuclides with  $N = Z$  are stable, such as  ${}^4_2\text{He}$ ,  ${}^{12}_6\text{C}$ ,  ${}^{16}_8\text{O}$ , and  ${}^{20}_{10}\text{Ne}$ ; the heaviest of these is  ${}^{40}_{20}\text{Ca}$ . Thus, for lighter nuclides, one neutron for each proton ( $N = Z$ ) is enough to provide stability.
- The  $N/Z$  ratio of stable nuclides gradually increases as  $Z$  increases. For example, for  ${}^{56}_{26}\text{Fe}$ ,  $N/Z = 1.15$ ; for  ${}^{107}_{47}\text{Ag}$ ,  $N/Z = 1.28$ ; for  ${}^{184}_{74}\text{W}$ ,  $N/Z = 1.49$ , and, finally, for  ${}^{209}_{83}\text{Bi}$ ,  $N/Z = 1.52$ . Thus, for heavier stable nuclides,  $N > Z$  ( $N/Z > 1$ ), and  $N$  increases faster than  $Z$ . As we discuss shortly, and show in Figure 24.2B, if  $N/Z$  of a nuclide is either too high (above the band) or not high enough (below the band), the nuclide is unstable and undergoes one of the three modes of beta decay.

**Figure 24.2** A plot of number of neutrons vs. number of protons for the stable nuclides.

**Table 24.4** Number of Stable Nuclides for Elements 48 to 54\*

Element	Atomic Number (Z)	Number of Nuclides
Cd	<b>48</b>	<b>8</b>
In	49	2
Sn	<b>50</b>	<b>10</b>
Sb	51	2
Te	<b>52</b>	<b>8</b>
I	53	1
Xe	<b>54</b>	<b>9</b>

\*Even values of Z are shown in **boldface**.

**Table 24.5** An Even-Odd Breakdown of the Stable Nuclides

Z	N	Number of Nuclides	Example
Even	Even	157	$^{84}_{38}\text{Sr}$
Even	Odd	53	$^{29}_{14}\text{Si}$
Odd	Even	50	$^{39}_{19}\text{K}$
Odd	Odd	4	$^{14}_{7}\text{N}$
Total		264	

- All nuclides with  $Z > 83$  are unstable.\* Thus, the largest members of Groups 1A(1) through 8A(18), actinium and the actinides ( $Z = 89\text{--}103$ ), and the other elements of the fourth ( $6d$ ) transition series ( $Z = 104\text{--}112$ ), are radioactive and (as discussed shortly) undergo  $\alpha$  decay.

**Stability and Nuclear Structure** Nuclear structure is related to nuclear stability in several ways:

1. *The effect of the strong force.* Given that protons are positively charged and neutrons are uncharged, the first question that arises is: why does the nucleus stay together? Nuclear scientists answer this question and explain the importance of  $N$  and  $Z$  values in terms of two opposing forces: electrostatic repulsive forces between protons would break the nucleus apart if not for an attractive force called the **strong force**, which exists between all nucleons (protons and neutrons). This force is 137 times stronger than the repulsive force but *operates only over the short distances within the nucleus*. Thus, the *attractive* strong force overwhelms the much weaker *repulsive* electrostatic force and keeps the nucleus together.

2. *Odd and even numbers of nucleons.* The oddness or evenness of  $N$  and  $Z$  values is related to some important patterns of nuclear stability. Two interesting points become apparent when we classify the known stable nuclides:

- Elements with an even  $Z$  (number of protons) usually have a larger number of stable nuclides than elements with an odd  $Z$ . Table 24.4 demonstrates this point for cadmium ( $Z = 48$ ) through xenon ( $Z = 54$ ).
- Well over half the stable nuclides have *both* even  $N$  and even  $Z$  (Table 24.5). Only four nuclides with odd  $N$  and odd  $Z$  are stable:  $^2_1\text{H}$ ,  $^6_3\text{Li}$ ,  $^{10}_5\text{B}$ , and  $^{14}_7\text{N}$ .

3. *Nucleon energy levels.* One model of nuclear structure that attempts to explain the stability of even values of  $N$  and  $Z$  postulates that protons and neutrons lie in *nucleon energy levels*, and that greater stability results from the *pairing of spins* of like nucleons. (Note the analogy to electron energy levels and the stability from pairing of electron spins.)

Just as noble gases—with 2, 10, 18, 36, 54, and 86 electrons—are exceptionally stable because they have filled *electron* energy levels, nuclides with  $N$  or  $Z$  values of 2, 8, 20, 28, 50, 82 (and  $N = 126$ ) are exceptionally stable. These so-called *magic numbers* are thought to correspond to the numbers of protons or neutrons in filled *nucleon* energy levels. A few examples are  $^{50}_{22}\text{Ti}$  ( $N = 28$ ),  $^{88}_{38}\text{Sr}$  ( $N = 50$ ), and the ten stable nuclides of tin ( $Z = 50$ ). Some extremely stable nuclides have two magic numbers:  $^4_2\text{He}$ ,  $^{16}_8\text{O}$ ,  $^{40}_{20}\text{Ca}$ , and  $^{208}_{82}\text{Pb}$  ( $N = 126$ ).

### SAMPLE PROBLEM 24.2

### Predicting Nuclear Stability

**Problem** Which of the following nuclides would you predict to be stable and which radioactive: (a)  $^{18}_{10}\text{Ne}$ ; (b)  $^{32}_{16}\text{S}$ ; (c)  $^{236}_{90}\text{Th}$ ; (d)  $^{123}_{56}\text{Ba}$ ? Explain.

**Plan** In order to evaluate the stability of each nuclide, we determine the  $N$  and  $Z$  values, the  $N/Z$  ratio from  $(A - Z)/Z$ , and the value of  $Z$ ; then we compare the  $N/Z$  ratio with the stable values (from Figure 24.2A) and note whether  $Z$  and  $N$  are even or odd.

**Solution** (a) **Radioactive.** This nuclide has  $N = 8$  ( $18 - 10$ ) and  $Z = 10$ , so  $N/Z = \frac{18 - 10}{10} = 0.8$ . Except for hydrogen-1 and helium-3, no nuclides with  $N < Z$  are stable; despite its even  $N$  and  $Z$ , this nuclide has too few neutrons to be stable.

(b) **Stable.** This nuclide has  $N = Z = 16$ , so  $N/Z = 1.0$ . With  $Z < 20$  and even  $N$  and  $Z$ , this nuclide is most likely stable.

\*In 2003, French nuclear physicists discovered that  $^{209}_{83}\text{Bi}$  actually undergoes  $\alpha$  decay, but the half-life is  $1.9 \times 10^{19}$  yr, about a billion times longer than the estimated age of the universe. Bismuth ( $Z = 83$ ) can thus be considered stable.

(c) **Radioactive.** This nuclide has  $Z = 90$ , and every nuclide with  $Z > 83$  is radioactive.

(d) **Radioactive.** This nuclide has  $N = 67$  and  $Z = 56$ , so  $N/Z = 1.20$ . For  $Z$  values of 55 to 60, Figure 24.2A shows  $N/Z \geq 1.3$  for stable nuclides, so this nuclide has too few neutrons to be stable.

**Check** By consulting a table of isotopes, such as the one in the *CRC Handbook of Chemistry and Physics*, we find that our predictions are correct.

### FOLLOW-UP PROBLEMS

**24.2A** Predict whether each of the following nuclides is stable or radioactive, and explain your prediction: (a)  ${}_{5}^{10}\text{B}$ ; (b)  ${}_{23}^{58}\text{V}$ .

**24.2B** Why is  ${}_{15}^{31}\text{P}$  stable but  ${}_{15}^{30}\text{P}$  unstable?

**SOME SIMILAR PROBLEMS** 24.16–24.19

**Predicting the Mode of Decay** An unstable nuclide generally decays in a mode that shifts its  $N/Z$  ratio toward the band of stability. This fact is illustrated in Figure 24.2B, which expands the small region of  $Z = 54$  to 70 in Figure 24.2A to show the stable *and* many of the unstable nuclides in that region, as well as their modes of decay. Note the following points:

1. *Neutron-rich nuclides.* Nuclides with too many neutrons for stability (a high  $N/Z$  ratio) lie above the band of stability. They undergo  $\beta^-$  decay, which converts a neutron into a proton, thus reducing the value of  $N/Z$ . For example, C-14 undergoes  $\beta^-$  decay to produce a nuclide with a lower  $N/Z$  ratio:

2. *Proton-rich nuclides.* Nuclides with too many protons for stability (a low  $N/Z$  ratio) lie below the band of stability. They undergo  $\beta^+$  emission and/or  $e^-$  capture, both of which convert a proton into a neutron, thus increasing the value of  $N/Z$ . (The rate of  $e^-$  capture increases with  $Z$ , so  $\beta^+$  emission is more common among lighter elements and  $e^-$  capture more common among heavier elements.) The following nuclear reactions show the decay processes for two nuclides with low  $N/Z$  ratios:

3. *Heavy nuclides.* Nuclides with  $Z > 83$  (shown in Figure 24.2A) are too heavy to be stable and undergo  $\alpha$  decay, which reduces their  $Z$  and  $N$  values by two units per emission.

With the information in Figure 24.2, predicting the mode of decay of an unstable nuclide involves simply comparing its  $N/Z$  ratio with those in the nearby region of the band of stability. But, even without Figure 24.2, we can often make an educated guess about mode of decay. The atomic mass of an element is the weighted average of its naturally occurring isotopes. Therefore,

- The mass number  $A$  of a *stable* nuclide will be relatively close to the atomic mass.
- If an *unstable* nuclide of an element (given  $Z$ ) has an  $A$  value much higher than the atomic mass, *it is neutron rich and will probably decay by  $\beta^-$  emission.*
- If, on the other hand, an unstable nuclide has an  $A$  value much lower than the atomic mass, *it is proton rich and will probably decay by  $\beta^+$  emission and/or  $e^-$  capture.*

In the next sample problem, we predict the mode of decay of some unstable nuclides.

### Student Hot Spot

Student data indicate that you may struggle with predicting a radioactive nuclide's mode of decay. Access the Smartbook to view additional Learning Resources on this topic.

## SAMPLE PROBLEM 24.3

## Predicting the Mode of Nuclear Decay

**Problem** Use the atomic mass of the element to predict the mode(s) of decay of the following radioactive nuclides: (a)  ${}^{12}_5\text{B}$ ; (b)  ${}^{234}_{92}\text{U}$ ; (c)  ${}^{81}_{33}\text{As}$ ; (d)  ${}^{127}_{57}\text{La}$ .

**Plan** If the nuclide is too heavy to be stable ( $Z > 83$ ), it undergoes  $\alpha$  decay. For other cases, we use the  $Z$  value to obtain the atomic mass from the periodic table. If the mass number of the nuclide is higher than the atomic mass, the nuclide has too many neutrons:  $N$  too high  $\Rightarrow \beta^-$  decay. If the mass number is lower than the atomic mass, the nuclide has too many protons:  $Z$  too high  $\Rightarrow \beta^+$  emission and/or  $e^-$  capture.

**Solution** (a) This nuclide has  $Z = 5$ , which is boron (B), and the atomic mass is 10.81. The nuclide's  $A$  value of 12 is significantly higher than its atomic mass, so this nuclide is neutron rich. It will probably undergo  $\beta^-$  decay.

(b) This nuclide has  $Z = 92$ , so it will undergo  $\alpha$  decay and decrease its total mass.

(c) This nuclide has  $Z = 33$ , which is arsenic (As), and the atomic mass is 74.92. The  $A$  value of 81 is much higher, so this nuclide is neutron rich and will probably undergo  $\beta^-$  decay.

(d) This nuclide has  $Z = 57$ , which is lanthanum (La), and the atomic mass is 138.9. The  $A$  value of 127 is much lower, so this nuclide is proton rich and will probably undergo  $\beta^+$  emission and/or  $e^-$  capture.

**Check** To confirm our predictions in parts (a), (c), and (d), let's compare each nuclide's  $N/Z$  ratio to those in the band of stability: (a) This nuclide has  $N = 7$  and  $Z = 5$ , so  $N/Z = 1.40$ , which is too high for this region of the band, so it will undergo  $\beta^-$  decay. (c) This nuclide has  $N = 48$  and  $Z = 33$ , so  $N/Z = 1.45$ , which is too high for this region of the band, so it will undergo  $\beta^-$  decay. (d) This nuclide has  $N = 70$  and  $Z = 57$ , so  $N/Z = 1.23$ , which is too low for this region of the band, so it will undergo  $\beta^+$  emission and/or  $e^-$  capture. Our predictions based on  $N/Z$  values were the same as those based on atomic mass.

**Comment** Both possible modes of decay are observed for the nuclide in part (d).

## FOLLOW-UP PROBLEMS

**24.3A** Use the  $A$  value for the nuclide and the atomic mass from the periodic table to predict the mode of decay of (a)  ${}^{61}_{26}\text{Fe}$ ; (b)  ${}^{241}_{95}\text{Am}$ .

**24.3B** Use the  $A$  value for the nuclide and the atomic mass from the periodic table to predict the mode of decay of (a)  ${}^{40}_{22}\text{Ti}$ ; (b)  ${}^{65}_{27}\text{Co}$ .

**SOME SIMILAR PROBLEMS** 24.20–24.23

Figure 24.3 The  ${}^{238}\text{U}$  decay series.

**Decay Series** A parent nuclide may undergo a series of decay steps before a stable daughter nuclide forms. The succession of steps is called a **decay series**, or **disintegration series**, and is typically depicted on a gridlike display. Figure 24.3 shows the decay series from uranium-238 to lead-206. Number of neutrons ( $N$ ) is plotted against number of protons ( $Z$ ) to form the grid, which displays a series of  $\alpha$  and  $\beta^-$  decays. The typical zigzag pattern arises because  $N > Z$ , which means that  $\alpha$  decay, which reduces both  $N$  and  $Z$  by two units, decreases  $Z$  slightly more than it does  $N$ . Therefore,  $\alpha$  decays result in neutron-rich daughters, which undergo  $\beta^-$  decay to gain more stability. Note that a given nuclide can undergo both modes of decay. (Gamma emission accompanies many of these steps but does not affect the type of nuclide.)

The series in Figure 24.3 is one of three that occur in nature. All end with isotopes of lead whose nuclides all have one ( $Z = 82$ ) or two ( $N = 126$ ,  $Z = 82$ ) magic numbers. A second series begins with uranium-235 and ends with lead-207, and a third begins with thorium-232 and ends with lead-208. (Neptunium-237 began a fourth series, but its half-life is so much less than the age of Earth that only traces of it remain today.)

## › Summary of Section 24.1

- › In dramatic contrast to chemical reactions, nuclear reactions involve particles *within* the nucleus, usually result in atoms of different elements, are accompanied by measurable changes in mass, and are not affected by temperature, pressure, catalysis, or the nature of the compound.
- › To become more stable, a radioactive nuclide may emit  $\alpha$  particles ( ${}^4_2\text{He}^{2+}$ ; helium-4 nuclei),  $\beta$  particles ( $\beta^-$  or  ${}^0_{-1}\beta$ ; high-speed electrons), positrons ( $\beta^+$  or  ${}^0_1\beta$ ), or  $\gamma$  rays (high-energy photons) or may capture an orbital electron ( ${}^0_{-1}\text{e}$ ).
- › A narrow band of neutron-to-proton ratios ( $N/Z$ ) includes those of all the stable nuclides.
- › Even values of  $N$  and  $Z$  are associated with stable nuclides, as are certain “magic numbers” of neutrons and protons.
- › By comparing a nuclide’s mass number with the atomic mass and its  $N/Z$  ratio with those in the band of stability, we can predict that, in general, neutron-rich nuclides undergo  $\beta^-$  decay and proton-rich nuclides undergo  $\beta^+$  emission and/or  $e^-$  capture. Heavy nuclides ( $Z > 83$ ) undergo  $\alpha$  decay.
- › Three naturally occurring decay series all end in isotopes of lead.

## 24.2 THE KINETICS OF RADIOACTIVE DECAY

Both chemical and nuclear systems tend toward maximum stability. Just as the concentrations in a chemical system change in a predictable direction to give a stable equilibrium ratio, the type and number of nucleons in an unstable nucleus change in a predictable direction to give a stable  $N/Z$  ratio. As you know, however, the tendency of a chemical system to become more stable tells nothing about how long that process will take, and the same holds true for nuclear systems. In this section, we first see how radioactivity is detected and measured and then examine the kinetics of nuclear change; later, we’ll examine the energetics of nuclear change.

### Detection and Measurement of Radioactivity

Radioactive emissions interact with surrounding atoms. To determine the rate of nuclear decay, we measure radioactivity by observing the effects of these interactions over time. Because these effects can be electrically amplified billions of times, it is possible to detect the decay of a single nucleus. Ionization counters and scintillation counters are two devices used to measure radioactive emissions.

**Ionization Counters** An *ionization counter* detects radioactive emissions as they ionize a gas. Ionization produces free electrons and gaseous cations, which are attracted to electrodes that conduct a current to a recording device. The most common type of ionization counter is a **Geiger-Müller counter** (Figure 24.4, *next page*). It consists of a tube filled with an argon-methane mixture; the tube housing acts as the cathode, and a thin wire in the center of the tube acts as the anode. Emissions from the sample enter the tube through a thin window and strike argon atoms, producing  $\text{Ar}^+$  ions that migrate toward the cathode and free electrons that are accelerated toward the anode. These electrons collide with other argon atoms and free more electrons in an *avalanche effect*. The current created is amplified and appears as a meter reading and/or an audible click. An initial release of 1 electron can release  $10^{10}$  electrons in a microsecond, giving the Geiger-Müller counter great sensitivity.

**Scintillation Counters** In a **scintillation counter**, radioactive emissions are detected by their ability to excite atoms and cause them to emit light. The light-emitting substance in the counter, called a *phosphor*, is coated onto part of a *photomultiplier tube*, a device that increases the original electrical signal. Incoming radioactive particles strike the phosphor, which emits photons. Each photon, in turn, strikes a cathode, releasing an electron through the photoelectric effect (Section 7.1). This electron hits other portions of the tube that release increasing numbers of electrons, and the

**Figure 24.4** Detection of radioactivity by an ionization counter.

**Figure 24.5** A scintillation “cocktail” in tubes to be placed in the counter.

Source: © Meridian Biotechnologies Ltd.

resulting current is recorded. Liquid scintillation counters employ an organic mixture that contains a phosphor and a solvent (Figure 24.5). This “cocktail” dissolves the radioactive sample *and* emits pulses of light when excited by the emission. The number of pulses is proportional to the concentration of the radioactive substance. These counters are often used to measure  $\beta^-$  emissions from dissolved biological samples, particularly those containing compounds of  $^3\text{H}$  and  $^{14}\text{C}$ .

## The Rate of Radioactive Decay

*Radioactive nuclei decay at a characteristic rate, regardless of the chemical substance in which they occur.*

**Activity and the Decay Constant** The *decay rate*, or **activity** ( $\mathcal{A}$ ), of a radioactive sample is the change in number of nuclei ( $\mathcal{N}$ ) divided by the change in time ( $t$ ). As with a chemical reaction rate (Section 16.2), because the number of nuclei is *decreasing*, a minus sign precedes the expression to obtain a positive decay rate:

$$\text{Decay rate } (\mathcal{A}) = -\frac{\Delta\mathcal{N}}{\Delta t}$$

There are two common units of radioactivity:

- The SI unit of radioactivity is the **becquerel (Bq)**, defined as one disintegration per second (d/s):  $1 \text{ Bq} = 1 \text{ d/s}$ .
- A much larger and more common unit of radioactivity is the **curie (Ci)**, which was originally defined as the number of disintegrations per second in 1 g of radium-226, but is now a fixed quantity:  $1 \text{ Ci} = 3.70 \times 10^{10} \text{ d/s}$ . Because the curie is so large, the millicurie (mCi) and microcurie ( $\mu\text{Ci}$ ) are commonly used.

The radioactivity of a sample is often given as a *specific activity*, the decay rate per gram.

An activity is meaningful only when we consider the large number of nuclei in a macroscopic sample. Suppose there are  $1 \times 10^{15}$  radioactive nuclei of a particular type in a sample and they decay at a rate of 10% per hour. Although any particular nucleus in the sample might decay in a microsecond or in a million hours, the *average* of all decays results in 10% of the entire collection of nuclei disintegrating each hour.

During the first hour, 10% of the *original* number, or  $1 \times 10^{14}$  nuclei, will decay. During the next hour, 10% of the remaining  $9 \times 10^{14}$  nuclei, or  $9 \times 10^{13}$  nuclei, will decay. During the next hour, 10% of those remaining will decay, and so forth. Thus, for a large collection of radioactive nuclei, *the number decaying per unit time is proportional to the number present*:

$$\text{Decay rate } (\mathcal{A}) \propto \mathcal{N} \quad \text{or} \quad \mathcal{A} = k\mathcal{N}$$

where  $k$  is called the **decay constant** and is characteristic of each type of nuclide. The larger the value of  $k$ , the higher the decay rate: **larger  $k \implies$  higher  $\mathcal{A}$** .

Combining the two expressions for decay rate just given, we obtain

$$\mathcal{A} = -\frac{\Delta \mathcal{N}}{\Delta t} = k\mathcal{N} \quad (24.2)$$

Note that the activity depends only on  $\mathcal{N}$  raised to the first power (and on the constant value of  $k$ ). Therefore, *radioactive decay is a first-order process* (Section 16.4), but first order with respect to the *number* of nuclei rather than their concentration.

#### SAMPLE PROBLEM 24.4

#### Calculating the Specific Activity and the Decay Constant of a Radioactive Nuclide

**Problem** A sample of  $2.6 \times 10^{-12}$  mol of antimony-122 ( $^{122}\text{Sb}$ ) emits  $2.76 \times 10^8$   $\beta^-$  particles per minute.

- Calculate the specific activity of the sample (in Ci/g).
- Find the decay constant for  $^{122}\text{Sb}$ .

**Plan** (a) The activity ( $\mathcal{A}$ ) is the number of nuclei ( $\mathcal{N}$ ) emitting a particle in a given time ( $t$ ), and the specific activity is the activity per gram of sample. We are given  $\mathcal{A}$ , which is equal to the number of particles emitted per minute ( $2.76 \times 10^8$   $\beta^-$  particles), and we know the amount (mol) of sample. Because the sample is an isotope, we use the mass number in g/mol (122 g/mol) to find the mass (g). Converting  $\mathcal{A}$  (in d/min) to curies (in d/s) and dividing by the mass gives the specific activity (in Ci/g). (b) The decay constant ( $k$ ) relates the activity to the number of nuclei ( $\mathcal{N}$ ). We know  $\mathcal{A}$  (number of nuclei disintegrating/min) and the amount (in mol), so we use Avogadro's number to find  $\mathcal{N}$  (number of nuclei) and apply Equation 24.2 to get  $k$ .

**Solution** a. Finding the mass of the sample:

$$\begin{aligned} \text{Mass (g)} &= (2.6 \times 10^{-12} \text{ mol } ^{122}\text{Sb}) \left( \frac{122 \text{ g } ^{122}\text{Sb}}{1 \text{ mol } ^{122}\text{Sb}} \right) \\ &= 3.2 \times 10^{-10} \text{ g } ^{122}\text{Sb} \end{aligned}$$

Using the activity and the mass to find the specific activity:

$$\begin{aligned} \text{Specific activity (Ci/g)} &= \left( \frac{2.76 \times 10^8 \text{ d}}{\text{min}} \right) \left( \frac{1 \text{ min}}{60 \text{ s}} \right) \left( \frac{1 \text{ Ci}}{3.70 \times 10^{10} \text{ d/s}} \right) \left( \frac{1}{3.2 \times 10^{-10} \text{ g}} \right) \\ &= 3.9 \times 10^5 \text{ Ci/g} \end{aligned}$$

- Using the activity and the amount to find the decay constant (Equation 24.2):

$$\begin{aligned} \text{Decay constant } (k) &= \frac{\mathcal{A} (\text{nuclei/min})}{\mathcal{N} (\text{nuclei})} = \frac{2.76 \times 10^8 \text{ nuclei/min}}{(2.6 \times 10^{-12} \text{ mol})(6.022 \times 10^{23} \text{ nuclei/mol})} \\ &= 1.8 \times 10^{-4} \text{ min}^{-1} \end{aligned}$$

**Check** With so many exponents in the values, rounding is a good way to check the math. In part (b), for example,

$$k = \frac{3 \times 10^8 \text{ nuclei/min}}{(3 \times 10^{-12} \text{ mol})(6 \times 10^{23} \text{ nuclei/mol})} = 2 \times 10^{-4} \text{ min}^{-1}$$

#### FOLLOW-UP PROBLEMS

**24.4A** Arsenic-76 decays by  $\beta^-$  emission. If  $3.4 \times 10^{-8}$  mol of  $^{76}\text{As}$  emits  $1.53 \times 10^{11}$   $\beta^-$  particles per second, find the specific activity in (a) Ci/g; (b) Bq/g.

**24.4B** Chlorine-36 disintegrates by  $\beta^-$  decay. If  $6.50 \times 10^{-2}$  mol of  $^{36}\text{Cl}$  emits  $9.97 \times 10^{12}$   $\beta^-$  particles per hour, find the decay constant.

**SOME SIMILAR PROBLEMS** 24.33–24.40

**Figure 24.6** Decrease in number of  $^{14}\text{C}$  nuclei over time.

**Half-Life of Radioactive Decay** Decay rates are also commonly expressed in terms of the fraction of nuclei that decay over a given time interval. The **half-life** ( $t_{1/2}$ ) of a nuclide has the same meaning as for a chemical change (Section 16.4) and can be expressed in terms of number of nuclei, mass of radioactive substance, and activity:

- **Number of nuclei.** Half-life is the time it takes for half the nuclei in a sample to decay—the number of nuclei remaining is halved after each half-life. Figure 24.6 shows the decay of carbon-14, which has a half-life of 5730 years (yr), in terms of number of  $^{14}\text{C}$  nuclei remaining:

- **Mass.** As  $^{14}\text{C}$  decays, the mass of  $^{14}\text{C}$  decreases while the mass of  $^{14}\text{N}$  increases. If we start with 1.0 g of  $^{14}\text{C}$ , half that mass of  $^{14}\text{C}$  (0.50 g) will be left after 5730 yr, half of that mass (0.25 g) after another 5730 yr, and so on.
- **Activity.** The activity depends on the number of nuclei, so the activity is halved after each succeeding half-life.

We determine the half-life of a nuclear reaction from its rate constant. Rearranging Equation 24.2 and integrating over time gives an expression for finding the number of nuclei remaining,  $N_t$ , after a given time  $t$ :

$$\ln \frac{N_t}{N_0} = -kt \quad \text{or} \quad N_t = N_0 e^{-kt} \quad \text{and} \quad \ln \frac{N_0}{N_t} = kt \quad (24.3)$$

where  $N_0$  is the number of nuclei at  $t = 0$ . (Note the similarity to Equation 16.4.) To calculate the half-life ( $t_{1/2}$ ), we set  $N_t$  equal to  $\frac{1}{2}N_0$  and solve for  $t_{1/2}$ :

$$\ln \frac{N_0}{\frac{1}{2}N_0} = kt_{1/2} \quad \text{so} \quad t_{1/2} = \frac{\ln 2}{k} \quad (24.4)$$

Exactly analogous to the half-life of a first-order chemical change, *this half-life is not dependent on the number of nuclei and is inversely related to the decay constant:*

$$\text{large } k \implies \text{short } t_{1/2} \quad \text{and} \quad \text{small } k \implies \text{long } t_{1/2}$$

The decay constants and half-lives of many radioactive nuclides vary over a very wide range, even for a given element (Table 24.6).

**Decay Constants ( $k$ ) and Half-Lives ( $t_{1/2}$ ) of Beryllium Isotopes**

**Table 24.6**

Nuclide	$k$	$t_{1/2}$
$^7_4\text{Be}$	$1.30 \times 10^{-2}/\text{day}$	53.3 days
$^8_4\text{Be}$	$1.0 \times 10^{16}/\text{s}$	$6.7 \times 10^{-17}$ s
$^9_4\text{Be}$	Stable	
$^{10}_4\text{Be}$	$4.3 \times 10^{-7}/\text{yr}$	$1.6 \times 10^6$ yr
$^{11}_4\text{Be}$	$5.02 \times 10^{-2}/\text{s}$	13.8 s

**SAMPLE PROBLEM 24.5****Finding the Number of Radioactive Nuclei**

**Problem** Strontium-90 is a radioactive byproduct of nuclear reactors that behaves biologically like calcium, the element above it in Group 2A(2). When  $^{90}\text{Sr}$  is ingested by mammals, it is found in their milk and eventually in the bones of those drinking the milk. If a sample of  $^{90}\text{Sr}$  has an activity of  $1.2 \times 10^{12}$  d/s, what are the activity and the fraction of nuclei that have decayed after 59 yr ( $t_{1/2}$  of  $^{90}\text{Sr} = 29$  yr)?

**Plan** The fraction of nuclei that have decayed is the change in number of nuclei, expressed as a fraction of the starting number. The activity of the sample ( $\mathcal{A}$ ) is proportional to the number of nuclei ( $N$ ), so we know that

$$\text{Fraction decayed} = \frac{N_0 - N_t}{N_0} = \frac{A_0 - A_t}{A_0}$$

We are given  $A_0$  ( $1.2 \times 10^{12}$  d/s), so we find  $A_t$  from the integrated form of the first-order rate equation (Equation 24.3), in which  $t$  is 59 yr. To solve that equation, we first need  $k$ , which we can calculate from the given  $t_{1/2}$  (29 yr) using Equation 24.4.

**Solution** Calculating the decay constant  $k$ :

$$t_{1/2} = \frac{\ln 2}{k} \quad \text{so} \quad k = \frac{\ln 2}{t_{1/2}} = \frac{0.693}{29 \text{ yr}} = 0.024 \text{ yr}^{-1}$$

Applying Equation 24.3 to calculate  $A_t$ , the activity remaining at time  $t$ :

$$\ln \frac{N_0}{N_t} = \ln \frac{A_0}{A_t} = kt \quad \text{or} \quad \ln A_0 - \ln A_t = kt$$

So,  $\ln A_t = -kt + \ln A_0 = -(0.024 \text{ yr}^{-1} \times 59 \text{ yr}) + \ln (1.2 \times 10^{12} \text{ d/s})$

$$\ln A_t = -1.4 + 27.81 = 26.4$$

$$A_t = 2.9 \times 10^{11} \text{ d/s}$$

(All the data contain two significant figures, so we retained two in the answer.)

Calculating the fraction decayed:

$$\text{Fraction decayed} = \frac{A_0 - A_t}{A_0} = \frac{1.2 \times 10^{12} \text{ d/s} - 2.9 \times 10^{11} \text{ d/s}}{1.2 \times 10^{12} \text{ d/s}} = 0.76$$

**Check** The answer is reasonable:  $t$  is about 2 half-lives, so  $A_t$  should be about  $\frac{1}{4}A_0$ , or about  $0.3 \times 10^{12}$ ; therefore, the activity should have decreased by about  $\frac{3}{4}$ .

**Comment 1.** A substitution in Equation 24.3 is useful for finding  $A_t$ , the activity at time  $t$ :  $A_t = A_0 e^{-kt}$ .

**2.** Another way to find the fraction of activity (or nuclei) remaining uses the number of half-lives ( $t/t_{1/2}$ ). By combining Equations 24.3 and 24.4 and substituting  $(\ln 2)/t_{1/2}$  for  $k$ , we obtain

$$\ln \frac{N_0}{N_t} = \left( \frac{\ln 2}{t_{1/2}} \right) t = \frac{t}{t_{1/2}} \ln 2 = \ln 2^{\frac{t}{t_{1/2}}}$$

Inverting the ratio gives

$$\ln \frac{N_t}{N_0} = \ln \left( \frac{1}{2} \right)^{\frac{t}{t_{1/2}}}$$

Taking the antilog gives

$$\text{Fraction remaining} = \frac{N_t}{N_0} = \left( \frac{1}{2} \right)^{\frac{t}{t_{1/2}}} = \left( \frac{1}{2} \right)^{\frac{59}{29}} = 0.24$$

So,  $\text{Fraction decayed} = 1.00 - 0.24 = 0.76$

### FOLLOW-UP PROBLEMS

**24.5A** Sodium-24 ( $t_{1/2} = 15$  h) is used to study blood circulation. If a patient is injected with an aqueous solution of  $^{24}\text{NaCl}$  whose activity is  $2.5 \times 10^9$  d/s, how much of the activity is present in the patient's body and excreted fluids after 4.0 days?

**24.5B** Iron-59 ( $t_{1/2} = 44.5$  days) is a  $\beta^-$  emitter used to monitor spleen function during disease or after trauma. If an accident victim receives a  $5.6\text{-}\mu\text{Ci}$  dose, what fraction of the  $^{59}\text{Fe}$  nuclei will have decayed after 17 days?

**SOME SIMILAR PROBLEMS** 24.41 and 24.42

## Radioisotopic Dating

The historical record fades rapidly with time and is virtually nonexistent for events of more than a few thousand years ago. Much knowledge of prehistory comes from **radioisotopic dating**, which uses unstable isotopes, or **radioisotopes**, to determine the ages of objects. This technique supplies data in fields such as art history, archeology, geology, and paleontology.

The technique of *radiocarbon dating*, for which the American chemist Willard F. Libby won the Nobel Prize in chemistry in 1960, is based on measuring the amounts

of  $^{14}\text{C}$  and  $^{12}\text{C}$  in materials of biological origin. The accuracy of the method falls off after about six half-lives of  $^{14}\text{C}$  ( $t_{1/2} = 5730$  yr), so it is used to date objects up to about 36,000 years old.

Here is how radiocarbon dating works:

1. High-energy cosmic rays, consisting mainly of protons, enter the atmosphere from outer space and initiate a cascade of nuclear reactions, some of which produce neutrons that bombard ordinary  $^{14}\text{N}$  atoms to form  $^{14}\text{C}$ :

Through the competing processes of formation and radioactive decay, the amount of  $^{14}\text{C}$  in the atmosphere has remained nearly constant.\*

2. The  $^{14}\text{C}$  atoms combine with  $\text{O}_2$ , diffuse throughout the lower atmosphere, and enter the total carbon pool as gaseous  $^{14}\text{CO}_2$  and aqueous  $\text{H}^{14}\text{CO}_3^-$ . They mix with ordinary  $^{12}\text{CO}_2$  and  $\text{H}^{12}\text{CO}_3^-$ , reaching a constant  $^{12}\text{C}/^{14}\text{C}$  ratio of about  $10^{12}/1$ .
3. The  $\text{CO}_2$  is taken up by plants during photosynthesis, and then taken up and excreted by animals that eat the plants. Thus, the  $^{12}\text{C}/^{14}\text{C}$  ratio of a living organism is the same as the ratio in the environment.
4. When an organism dies, it no longer absorbs or releases  $\text{CO}_2$ , so the  $^{12}\text{C}/^{14}\text{C}$  ratio steadily increases because *the amount of  $^{14}\text{C}$  decreases as it decays*:

The difference between the  $^{12}\text{C}/^{14}\text{C}$  ratio in a dead organism and the ratio in living organisms reflects the time elapsed since the organism died.

As you saw in Sample Problem 24.5, the first-order rate equation can be expressed in terms of a ratio of activities:

$$\ln \frac{\mathcal{N}_0}{\mathcal{N}_t} = \ln \frac{\mathcal{A}_0}{\mathcal{A}_t} = kt$$

We use this expression in radiocarbon dating, where  $\mathcal{A}_0$  is the activity in a living organism and  $\mathcal{A}_t$  is the activity in the object whose age is unknown. Solving for  $t$  gives the age of the object:

$$t = \frac{1}{k} \ln \frac{\mathcal{A}_0}{\mathcal{A}_t} \quad (24.5)$$

A graphical method used in radioisotopic dating shows a plot of the natural logarithm of the specific activity vs. time, which gives a straight line with a slope of  $-k$ , the negative of the decay constant. Using such a plot and measuring the  $^{14}\text{C}$  specific activity of an object, we can determine its age; examples appear in Figure 24.7.

One well-known example of the use of radiocarbon dating was in the determination of the age of the Shroud of Turin (*see photo*). One of the holiest Christian relics, the shroud is a piece of linen that bears a faint image of a man's body and was thought to be the burial cloth used to wrap the body of Jesus Christ. However, three labs in Europe and the United States independently measured the  $^{12}\text{C}/^{14}\text{C}$  ratio of a 50-mg piece of the linen and determined that the flax from which the cloth was made was grown between 1260 A.D. and 1390 A.D.

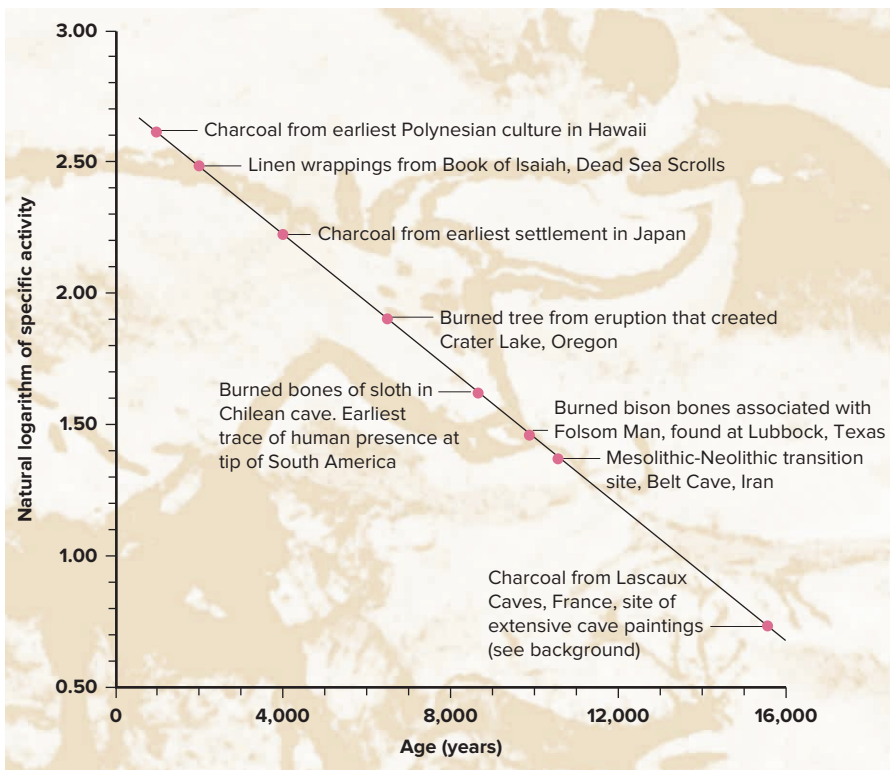

To determine the ages of more ancient objects or of objects that do not contain carbon, different radioisotopes are measured. For example, comparing the ratio of  $^{238}\text{U}$  ( $t_{1/2} = 4.5 \times 10^9$  yr) to its final decay product,  $^{206}\text{Pb}$ , in meteorites gives 4.7 billion years for the age of the Solar System, and therefore Earth. From this and other isotope ratios, such as  $^{40}\text{K}/^{40}\text{Ar}$  ( $t_{1/2}$  of  $^{40}\text{K} = 1.3 \times 10^9$  yr) and  $^{87}\text{Rb}/^{87}\text{Sr}$  ( $t_{1/2}$  of  $^{87}\text{Rb} = 4.9 \times 10^{10}$  yr), Moon rocks collected by Apollo astronauts have been dated at 4.2 billion years old.

The Shroud of Turin.

\*Cosmic ray intensity does vary slightly with time, which affects the amount of atmospheric  $^{14}\text{C}$ . From  $^{14}\text{C}$  activity in ancient trees, we know the amount fell slightly about 3000 years ago to current levels. Recently, nuclear testing and fossil-fuel combustion have also altered the fraction of  $^{14}\text{C}$  slightly. Taking these factors into account improves the accuracy of the dating method.

**Figure 24.7** Ages of several objects determined by radiocarbon dating.

### SAMPLE PROBLEM 24.6

### Applying Radiocarbon Dating

**Problem** The charred bones of a sloth in a cave in Chile represent the earliest evidence of human presence at the southern tip of South America. A sample of the bone has a specific activity of 5.22 disintegrations per minute per gram of carbon (d/min·g). If the  $^{12}\text{C}/^{14}\text{C}$  ratio for living organisms results in a specific activity of 15.3 d/min·g, how old are the bones ( $t_{1/2}$  of  $^{14}\text{C} = 5730$  yr)?

**Plan** We calculate  $k$  from the given  $t_{1/2}$  (5730 yr). Then we apply Equation 24.5 to find the age ( $t$ ) of the bones, using the given activities of the bones ( $\mathcal{A}_t = 5.22$  d/min·g) and of a living organism ( $\mathcal{A}_0 = 15.3$  d/min·g).

**Solution** Calculating  $k$  for  $^{14}\text{C}$  decay:

$$k = \frac{\ln 2}{t_{1/2}} = \frac{0.693}{5730 \text{ yr}} = 1.21 \times 10^{-4} \text{ yr}^{-1}$$

Calculating the age ( $t$ ) of the bones:

$$t = \frac{1}{k} \ln \frac{\mathcal{A}_0}{\mathcal{A}_t} = \frac{1}{1.21 \times 10^{-4} \text{ yr}^{-1}} \ln \left( \frac{15.3 \text{ d/min}\cdot\text{g}}{5.22 \text{ d/min}\cdot\text{g}} \right) = 8.89 \times 10^3 \text{ yr}$$

The bones are about 8890 years old.

**Check** The activity of the bones is between  $\frac{1}{2}$  and  $\frac{1}{4}$  of the activity of a living organism, so the age of the bones should be between one and two half-lives of  $^{14}\text{C}$  (from 5730 to 11,460 yr).

### FOLLOW-UP PROBLEMS

**24.6A** A sample of wood from an Egyptian mummy case has a specific activity of 9.41 d/min·g. How old is the case ( $t_{1/2}$  of  $^{14}\text{C} = 5730$  yr)?

**24.6B** A fragment of a woolen tunic found in an ancient cemetery in Africa has a specific activity of 12.87 d/min·g. How old is the tunic ( $t_{1/2}$  of  $^{14}\text{C} = 5730$  yr)?

**SOME SIMILAR PROBLEMS** 24.43 and 24.44

### › Summary of Section 24.2

- › Ionization and scintillation counters measure the number of emissions from a radioactive sample.
- › The decay rate (activity) of a sample is proportional to the number of radioactive nuclei. Nuclear decay is a first-order process, so the half-life of the process is a constant.
- › Radioisotopic methods, such as  $^{14}\text{C}$  dating, determine the age of an object by measuring the ratio of specific isotopes in it.

## 24.3 NUCLEAR TRANSMUTATION: INDUCED CHANGES IN NUCLEI

The alchemists' dream of changing base metals into gold was never realized, but in the early 20<sup>th</sup> century, nuclear physicists *did* change one element into another. Research on **nuclear transmutation**, the *induced* conversion of the nucleus of one element into the nucleus of another, was closely linked to research on atomic structure and led to the discovery of the neutron and the production of artificial radioisotopes. Later, high-energy bombardment of nuclei in particle accelerators began the ongoing effort to create new nuclides and new elements, and, most recently, to understand fundamental questions of matter and energy.

### Early Transmutation Experiments; Nuclear Shorthand Notation

The first recognized transmutation occurred in 1919, when Ernest Rutherford showed that  $\alpha$  particles emitted from radium bombarded atmospheric nitrogen to form a proton and oxygen-17:

By 1926, experimenters had found that  $\alpha$  bombardment transmuted most elements with low atomic numbers to the next higher element, with ejection of a proton.

**Notation for Transmutation Reactions** A shorthand notation used specifically for nuclear transmutation reactions shows the reactant (target) nucleus to the left and the product nucleus to the right of a set of parentheses, within which a comma separates the projectile particle from the ejected particle(s):

Using this notation, we write the previous reaction as  ${}^{14}\text{N} (\alpha, \text{p}) {}^{17}\text{O}$ .

**The Neutron and the First Artificial Radioisotope** An unexpected finding in a transmutation experiment led to *the discovery of the neutron*. When lithium, beryllium, and boron were bombarded with  $\alpha$  particles, they emitted highly penetrating radiation that could not be deflected by a magnetic or electric field. Unlike  $\gamma$  radiation, these emissions were massive enough to eject protons from the substances they penetrated. In 1932, James Chadwick, a student of Rutherford, proposed that the emissions consisted of neutral particles with a mass similar to that of a proton, which he named *neutrons*. He received the Nobel Prize in physics in 1935 for his discovery.

In 1933, Irene and Frederic Joliot-Curie (*see photo*), daughter and son-in-law of Marie and Pierre Curie, created the first artificial radioisotope, phosphorus-30. When they bombarded aluminum foil with  $\alpha$  particles, phosphorus-30 and neutrons were formed:

Since then, other techniques for producing artificial radioisotopes have been developed. In fact, the majority of the nearly 1000 known radioactive nuclides have been produced artificially.

The Joliot-Curies in their laboratory.

## Particle Accelerators and the Transuranium Elements

During the 1930s and 1940s, researchers probing the nucleus bombarded elements with neutrons,  $\alpha$  particles, protons, and **deuterons** (nuclei of the stable hydrogen isotope deuterium,  $^2\text{H}$ ). Neutrons are especially useful as projectiles because they have no charge and thus are not repelled as they approach a target nucleus. The other particles are all positive, so early researchers found it difficult to give them enough energy to overcome the repulsion of the target nuclei. Beginning in the 1930s, however, **particle accelerators** were able to impart high kinetic energies to particles by placing them in an electric field, usually in combination with a magnetic field. In the simplest and earliest design, protons are introduced at one end of a tube and attracted to the other end by a potential difference.

**Linear Accelerator** A major advance was the *linear accelerator*, a series of separated tubes of increasing length that, through a source of alternating voltage, change their charge from positive to negative in synchrony with the movement of the particle through them (Figure 24.8).

**Figure 24.8** Schematic diagram of a linear accelerator.

A proton, for example, exits the first tube just when that tube becomes positive and the next tube negative. Repelled by the first tube and attracted by the second, the proton accelerates across the gap between them. The process is performed in stages to achieve high particle energies without having to apply a single very high voltage. A 40-ft linear accelerator with 46 tubes, built in California after World War II, accelerated protons to speeds several million times faster than earlier accelerators.

**Other Early Particle Accelerators** Two other early accelerators represented important design advances:

- The *cyclotron* (Figure 24.9, *next page*) was invented by E. O. Lawrence in 1930. Typically 1–2 m in diameter, it applies the principle of the linear accelerator but uses electromagnets to give the particle a spiral path to save space. The magnets lie within an evacuated chamber above and below two “dees,” open, D-shaped electrodes that act like the tubes in the linear design. The particle is accelerated as it passes from one dee, which is momentarily positive, to the other, which is momentarily negative. Its speed and path radius increase until it is deflected toward the target nucleus.
- The *synchrotron* uses a synchronously increasing magnetic field to make the particle’s path circular rather than spiral.

**Powerful Modern Accelerators** Some very powerful accelerators that are used to study the physics of high-energy particle collisions include both a linear section and a synchrotron section. The *tevatron* at the Fermi Lab near Chicago has a circumference of 3.9 miles and can accelerate particles to an energy slightly less than  $1 \times 10^{12}$  electron volts (1 TeV) before colliding them.

The world’s most powerful accelerator is the Large Hadron Collider (LHC) near Geneva, Switzerland (*see photo*). The first successful collision of protons in the LHC was achieved in early 2010. When operating at peak capacity, the LHC accelerates protons to an energy of up to 13 TeV as they travel around the main ring at a speed of 11,000 revolutions per second, attaining a final speed about 99.99% of the speed

A small section of the Large Hadron Collider.

of light before colliding with other protons. Physicists are now studying the results of these high-energy subatomic collisions for information on the fundamental nature of matter and the early universe.

**Synthesis of Transuranium Elements** Scientists use accelerators for many applications, from producing radioisotopes used in medical applications to studying the fundamental nature of matter. Perhaps the most specific application for chemists is the synthesis of **transuranium elements**, those with atomic numbers higher than uranium, the heaviest naturally occurring element. Some reactions that were used to form several of these elements appear in Table 24.7. The transuranium elements include the remaining actinides ( $Z = 93$  to  $103$ ), in which the  $5f$  sublevel is filled; the elements in the fourth transition series ( $Z = 104$  to  $112$ ), in which the  $6d$  sublevel is filled; and the remaining elements in the  $7p$  sublevel ( $Z = 113$  to  $118$ ).

**Table 24.7****Formation of Some Transuranium Nuclides\***

Reaction	Half-life of Product
${}_{94}^{239}\text{Pu} + {}_0^2\text{n} \longrightarrow {}_{95}^{241}\text{Am} + {}_0^{-1}\beta$	432 yr
${}_{94}^{239}\text{Pu} + {}_2^4\alpha \longrightarrow {}_{96}^{242}\text{Cm} + {}_0^1\text{n}$	163 days
${}_{95}^{241}\text{Am} + {}_2^4\alpha \longrightarrow {}_{97}^{243}\text{Bk} + {}_0^1\text{n}$	4.5 h
${}_{96}^{242}\text{Cm} + {}_2^4\alpha \longrightarrow {}_{98}^{245}\text{Cf} + {}_0^1\text{n}$	45 min
${}_{99}^{253}\text{Es} + {}_2^4\alpha \longrightarrow {}_{101}^{256}\text{Md} + {}_0^1\text{n}$	76 min
${}_{95}^{243}\text{Am} + {}_8^{18}\text{O} \longrightarrow {}_{103}^{256}\text{Lr} + {}_0^1\text{n}$	28 s

\*Like chemical reactions, nuclear reactions may occur in several steps. For example, the first reaction here is actually an overall process that occurs in three steps:

Conflicting claims of discovery by scientists in the United States and the former Soviet Union led to controversies about names for some of the more recently synthesized elements. To provide interim names until the disputes could be settled, the International Union of Pure and Applied Chemistry (IUPAC) adopted a system that uses the atomic number as the basis for a Latin name. Thus, for example, element 104 was named unnilquadium (un = 1, nil = 0, quad = 4, ium = metal suffix), with the symbol Unq. After much compromise, IUPAC has finalized the names of the new elements (*margin*).

Z	Name (Symbol)
104	rutherfordium (Rf)
105	dubnium (Db)
106	seaborgium (Sg)
107	bohrium (Bh)
108	hassium (Hs)
109	meitnerium (Mt)
110	darmstadtium (Ds)
111	roentgenium (Rg)
112	copernicium (Cn)
113	nihonium (Nh)
114	flerovium (Fl)
115	moscovium (Mc)
116	livermorium (Lv)
117	tennessine (Ts)
118	oganeson (Og)

## › Summary of Section 24.3

- › One nucleus can be transmuted to another through bombardment with high-energy particles.
- › Accelerators increase the kinetic energy of particles in nuclear bombardment experiments and are used to produce transuranium elements and radioisotopes for medical use.

## 24.4 IONIZATION: EFFECTS OF NUCLEAR RADIATION ON MATTER

In 1986, an accident at the Chernobyl nuclear facility in the former Soviet Union released radioactivity that, according to the World Health Organization, will eventually cause thousands of cancer deaths. In the same year, isotopes used in medical treatment emitted radioactivity that prevented thousands of cancer deaths. In this section and Section 24.5, we examine radioactivity's harmful and beneficial effects.

The key to both types of effects is that *nuclear changes cause chemical changes in surrounding matter*. In other words, even though the nucleus of an atom may undergo a reaction with little or no involvement of the atom's electrons, the emissions from that reaction *do* affect the electrons of nearby atoms.

Virtually all radioactivity causes **ionization** in surrounding matter, as the emissions collide with atoms and dislodge electrons:

From each ionization event, a cation and a free electron result, and the number of such *cation-electron pairs* produced is directly related to the energy of the incoming **ionizing radiation**.

Many applications of ionizing radiation depend not only on the ionizing event itself, but also on secondary processes. For example, in a Geiger-Müller counter, the free electron of the cation-electron pair often collides with another atom, which ejects a second electron, and in a scintillation counter, the initial ionization eventually results in the emission of light. In nuclear power plants (Section 24.7), the initial process as well as several secondary processes cause the release of heat that makes the steam used to generate electricity.

### Effects of Ionizing Radiation on Living Tissue

Ionizing radiation has a destructive effect on living tissue, and if the ionized atom is part of a key biological macromolecule or cell membrane, the results can be devastating to the cell and perhaps the organism.

The danger from a radioactive nuclide depends on three factors:

- the type of radiation emitted,
- the half-life of the radioactive nuclide, and
- most importantly, the biological behavior of the radioactive nuclide.

For example, both  $^{235}\text{U}$  and  $^{239}\text{Pu}$  emit  $\alpha$  particles and have long half-lives, but uranium is rapidly excreted by the body, whereas plutonium behaves like calcium and, thus, is incorporated into bones and teeth. One of the most dangerous radioactive nuclides, even worse than plutonium, is  $^{90}\text{Sr}^{2+}$  (formed during a nuclear explosion) because it behaves very similarly to  $\text{Ca}^{2+}$  and is absorbed rapidly by bones. Let's first see how to measure radiation dose and then look in more detail at the damaging power of ionizing radiation.

**Units of Radiation Dose and Its Effects** To measure the effects of ionizing radiation, we need a unit for radiation dose. Units of radioactive decay, such as the becquerel and curie, measure the number of decay events in a given time but

not their energy or absorption by matter. However, the number of cation-electron pairs produced in a given amount of living tissue *is* a measure of the energy absorbed by the tissue. Two pairs of related units are used to quantify this absorbed energy:

- The SI unit for energy absorption is the **gray (Gy)**; it is equal to 1 joule of energy absorbed per kilogram of body tissue:

$$1 \text{ Gy} = 1 \text{ J/kg}$$

- A more widely used unit is the **rad (radiation-absorbed dose)**, which is one-hundredth as large as the gray:

$$1 \text{ rad} = 0.01 \text{ J/kg} = 0.01 \text{ Gy}$$

To measure actual tissue damage, we must account for differences in the strength of the radiation, the exposure time, and the type of tissue. To do this, we multiply the absorbed dose by a *relative biological effectiveness (RBE)* factor, which depends on the effect a given type of radiation has on a given tissue or body part. The product is expressed in one of two units:

- The **rem (roentgen equivalent for man)** is the unit of radiation dosage equivalent to a given amount of tissue damage in a human:

$$\text{no. of rems} = \text{no. of rads} \times \text{RBE}$$

Doses are often expressed in millirems ( $10^{-3}$  rem).

- The SI unit for dosage equivalent is the **sievert (Sv)**. It is defined in the same way as the rem but with absorbed dose in grays; thus,  $1 \text{ Sv} = 100 \text{ rem}$ .

**Penetrating Power of Emissions** The effect on living tissue of a radiation dose depends on the penetrating power *and* ionizing ability of the radiation. Since water is the main component of living tissue, penetrating power is often measured in terms of the depth of water that stops 50% of incoming radiation. In Figure 24.10, the average values of the penetrating distances are shown in actual size for the three common types of emissions. Note, in general, that *penetrating power is inversely related to the mass, charge, and energy of the emission*. In other words, if a particle interacts strongly with matter, it penetrates only slightly, and vice versa.

1. *Alpha particles.* Alpha particles are massive and highly charged, which means that they interact with matter most strongly of the three common emissions. As a result, they penetrate so little that a piece of paper, light clothing, or the outer layer of skin can stop  $\alpha$  radiation from an external source. However, if ingested, an  $\alpha$  emitter can cause grave localized internal damage through extensive ionization. For example, in the early 20<sup>th</sup> century, wristwatch and clock dials were painted by hand with paint containing radium so that the numbers would glow in the dark. To write numbers clearly, the women who applied the paint “tipped” fine brushes repeatedly between their lips. Small amounts of ingested  $^{226}\text{Ra}^{2+}$  were incorporated into their bones along with normal  $\text{Ca}^{2+}$ , which led to numerous cases of bone fracture and jaw cancer.

2. *Beta particles and positrons.* Beta particles ( $\beta^-$ ) and positrons ( $\beta^+$ ) have less charge and much less mass than  $\alpha$  particles, so they interact less strongly with matter. Even though a given particle has less chance of causing ionization, a  $\beta^-$  (or  $\beta^+$ ) emitter is a more destructive external source because the particles penetrate deeper. Specialized heavy clothing or a thick (0.5 cm) piece of metal is required to stop these particles. The relative danger from  $\alpha$  and  $\beta^-$  emissions is shown by two international incidents involving poisoning. In 1957, an espionage agent was poisoned by thallium-204, a  $\beta^-$  emitter, but he survived because  $\beta^-$  particles do relatively little radiation damage. In contrast, in 2006, another agent was poisoned with polonium-210, an  $\alpha$  emitter, and died in three weeks because of the much greater radiation damage.

**Figure 24.10** Penetrating power of radioactive emissions.

3. *Gamma rays.* Neutral, massless  $\gamma$  rays interact least with matter and, thus, penetrate most. A block of lead several inches thick is needed to stop them. Therefore, an external  $\gamma$  ray source is the most dangerous because the energy can ionize many layers of living tissue.

The extent of interaction with matter is variable for emitted *neutrons*, which are neutral and massive. Outside a nucleus, neutrons decay with a half-life of 10.6 min into a proton and an electron (and an antineutrino). With energies ranging from very low to very high, they may be scattered or captured by interaction with nuclei.

**Molecular Interactions** How does the damage take place on the molecular level? When ionizing radiation interacts with molecules, it causes the *loss of an electron from a bond or a lone pair*. The resulting charged species go on to form **free radicals**, molecular or atomic species with one or more unpaired electrons, which, as you know, are very reactive (Section 10.1). They form electron pairs by attacking bonds in other molecules, often forming more free radicals. Two types of materials are especially vulnerable to free-radical attack:

1. *Water.* When  $\gamma$  radiation strikes living tissue, for instance, the most likely molecule to absorb it is water, yielding an electron and a water ion-radical:

The products collide with other water molecules to form more free radicals:

These free radicals attack more  $\text{H}_2\text{O}$  molecules and surrounding biomolecules, whose bonding and structure are intimately connected with their function (Section 15.6).

2. *Membranes and macromolecules.* The double bonds in membrane lipids are highly susceptible to free-radical attack:

In this reaction, one electron of the  $\pi$  bond forms a C—H bond between one of the double-bonded carbons and the  $\text{H}\bullet$ , and the other electron resides on the other carbon to form a free radical. Changes to lipid structure cause damage that results in leakage through cell membranes and destruction of the protective fatty tissue around organs. Changes to critical bonds in enzymes lead to their malfunction as catalysts of metabolic reactions. Changes in the nucleic acids and proteins that govern the rate of cell division can cause cancer. Genetic damage and mutations may occur when bonds in the DNA of sperm and egg cells are altered by free radicals.

## Background Sources of Ionizing Radiation

We are continuously exposed to ionizing radiation from natural and artificial sources (Table 24.8). Indeed, life evolved in the presence of natural ionizing radiation, called **background radiation**. Ionizing radiation can alter bonds in DNA and cause harmful mutations but also causes the beneficial ones that allow species to evolve.

Background radiation has several natural sources:

1. *Cosmic radiation* increases with altitude because of decreased absorption by the atmosphere. Thus, people in Denver absorb twice as much cosmic radiation as people in Los Angeles; even a single jet flight involves measurable absorption.

2. Thorium and uranium minerals are present in rocks and soil. Radon, the heaviest noble gas [Group 8A(18)], is a radioactive product of uranium and thorium decay. Its concentration in the air we breathe is related to the presence of trace minerals in building materials and to the uranium content of local soil and

Table 24.8

Typical Radiation Doses from Natural and Artificial Sources

Source of Radiation	Average Adult Exposure
<b>Natural</b>	
Cosmic radiation	30–50 mrem/yr
Radiation from the ground	
From clay soil and rocks	~25–170 mrem/yr
In wooden houses	10–20 mrem/yr
In brick houses	60–70 mrem/yr
In concrete (cinder block) houses	60–160 mrem/yr
Radiation from the air (mainly radon)	
Outdoors, average value	20 mrem/yr
In wooden houses	70 mrem/yr
In brick houses	130 mrem/yr
In concrete (cinder block) houses	260 mrem/yr
Internal radiation from minerals in tap water and daily intake of food ( $^{40}\text{K}$ , $^{14}\text{C}$ , Ra)	~40 mrem/yr
<b>Artificial</b>	
Diagnostic x-ray methods	
Lung (local)	0.04–0.2 rad/film
Kidney (local)	1.5–3 rad/film
Dental (dose to the skin)	≤1 rad/film
Therapeutic radiation treatment	Locally ≤10,000 rad
Other sources	
Jet flight (4 h)	~1 mrem
Nuclear testing	<4 mrem/yr
Nuclear power industry	<1 mrem/yr
<b>Total average value</b>	100–200 mrem/yr

Figure 24.11 Continental U.S. radon distribution.

rocks (Figure 24.11). Once it enters the body, radon poses a serious potential hazard as it decays to radioactive nuclides of Po, Pb, and Bi, through  $\alpha$ ,  $\beta^-$ , and  $\gamma$  emissions. The emissions damage lung tissue, and the heavy-metal atoms formed aggravate the problem. Recent EPA estimates indicate that radon contributes to 15% of annual lung cancer deaths.

3. About 150 g of  $\text{K}^+$  ions is dissolved in the water in the tissues of an average adult, and 0.0118% of these ions are radioactive  $^{40}\text{K}$ . The presence of these substances and of atmospheric  $^{14}\text{CO}_2$  makes *all* food, water, clothing, and building materials slightly radioactive.

The largest artificial source of radiation, and the one that is easiest to control, is from medical diagnostic techniques, especially x-rays. The radiation dosage from nuclear testing and radioactive waste disposal is miniscule for most people, but exposures for those living near test sites or disposal areas may be much higher.

## Assessing the Risk from Ionizing Radiation

How much radiation is too much? To answer this question, we must ask several others: How strong is the exposure? How long is the exposure? Which tissue is exposed? Are children being exposed? One reason we lack clear data to answer these questions is that scientific ethical standards forbid the intentional exposure of humans in an experimental setting. However, accidentally exposed radiation workers and Japanese atomic bomb survivors have been studied extensively.

1. *Human studies.* Table 24.9 summarizes the immediate effects on humans of an acute single dose of ionizing radiation to the whole body. The severity of the effects increases with dose; a dose of 500 rem will kill about 50% of the exposed population within a month.

Table 24.9

## Acute Effects of a Single Dose of Whole-Body Irradiation

Dose (rem)	Effect	Lethal Dose	
		Population (%)	Number of Days
5–20	Possible late effect; possible chromosomal aberrations	—	—
20–100	Temporary reduction in white blood cells	—	—
50+	Temporary sterility in men (100+ rem = 1-yr duration)	—	—
100–200	“Mild radiation sickness”: vomiting, diarrhea, tiredness in a few hours Reduction in infection resistance Possible bone growth retardation in children	—	—
300+	Permanent sterility in women	—	—
500	“Serious radiation sickness”: marrow/intestine destruction	50–70	30
400–1000	Acute illness, early deaths	60–95	30
3000+	Acute illness, death in hours to days	100	2

2. *Animal studies.* Most data on radiation risk come from laboratory animals, whose biological systems may differ greatly from ours. Nevertheless, studies with mice and dogs show that lesions and cancers appear after massive whole-body exposure, with rapidly dividing cells affected first. In an adult animal, these are cells of the bone marrow, organ linings, and reproductive organs, but many other tissues are affected in an immature animal or fetus.

3. *Models of risk assessment.* Studies in both animals and humans show an increase in the incidence of cancer from either a high, single exposure or a low, chronic exposure. Two current models of radiation risk are shown in Figure 24.12:

- The *linear response model* proposes that radiation effects, such as cancer risks, accumulate over time regardless of dose and that populations should not be exposed to any radiation above background levels.
- The *S-shaped response model* implies there is a threshold above which the effects are more significant: very low risk at low dose and high risk at high dose.

4. *Hereditary effects.* Reliable data on hereditary (genetic) effects of radiation are few. Studies on fruit flies show a linear increase in genetic defects with both dose and exposure time. However, in the mouse, whose genetic system is obviously much more similar to ours than is the fruit fly's, a total dose given over a long period created one-third as many genetic defects as the same dose given over a short period. Therefore, rate of exposure is a key factor. The children of atomic bomb survivors show higher-than-normal childhood cancer rates, implying that their parents' reproductive systems were affected.

## › Summary of Section 24.4

- › All radioactive emissions cause ionization.
- › The effect of ionizing radiation on living matter depends on the quantity of energy absorbed and the extent of ionization in a given type of tissue. Radiation dose for the human body is measured in rem.
- › Ionization forms free radicals, some of which proliferate and destroy biomolecular function.
- › All organisms are exposed to varying quantities of natural ionizing radiation.
- › Studies show that either a large acute dose or a chronic small dose is harmful.

Figure 24.12 Two models of radiation risk.

## 24.5 APPLICATIONS OF RADIOISOTOPES

Radioisotopes are powerful tools for studying processes in biochemistry, medicine, materials science, environmental studies, and many other scientific and industrial fields. Such uses depend on the fact that *isotopes of an element exhibit very similar chemical and physical behavior*. In other words, except for having a less stable nucleus, a radioisotope has nearly the same properties as a nonradioactive isotope of the same element.\* For example, the fact that  $^{14}\text{CO}_2$  is utilized by a plant in the same way as  $^{12}\text{CO}_2$  forms the basis of radiocarbon dating.

### Radioactive Tracers

Just think how useful it could be to follow a substance through a complex process or from one region of a system to another. A tiny amount of a radioisotope mixed with a large amount of a stable isotope of the same element can act as a **tracer**, a chemical “beacon” emitting radiation that signals the presence of the substance.

**Reaction Pathways** Tracers are used to study simple and complex reaction pathways.

1. *Inorganic systems: the periodate-iodide reaction.* One well-studied pathway is that of the reaction between periodate and iodide ions:

Is  $\text{IO}_3^-$  the result of  $\text{IO}_4^-$  reduction or  $\text{I}^-$  oxidation? When “cold” (nonradioactive)  $\text{IO}_4^-$  is added to a solution of  $\text{I}^-$  that contains some “hot” (radioactive, indicated in red)  $^{131}\text{I}^-$ , the  $\text{I}_2$  is the radioactive product, not the  $\text{IO}_3^-$ :

These results show that  $\text{IO}_3^-$  forms through the reduction of  $\text{IO}_4^-$ , and that  $\text{I}_2$  forms through the oxidation of  $\text{I}^-$ . To confirm this pathway,  $\text{IO}_4^-$  containing some  $^{131}\text{IO}_4^-$  is added to a solution of  $\text{I}^-$ . As expected, in this case, the  $\text{IO}_3^-$  is radioactive, not the  $\text{I}_2$ :

Thus, tracers act like “handles” we can “hold” to follow the changing reactants.

2. *Biochemical pathways: photosynthesis.* Far more complex pathways can be followed with tracers as well. The photosynthetic pathway, in which energy from sunlight is used to form the chemical bonds of glucose, is the most essential and widespread metabolic process on Earth. It has an overall reaction that looks quite simple:

However, the actual process is extremely complex: 13 enzyme-catalyzed steps are required to incorporate each C atom from  $\text{CO}_2$ , so the six  $\text{CO}_2$  molecules needed to form a molecule of  $\text{C}_6\text{H}_{12}\text{O}_6$  require six repetitions of the pathway. Melvin Calvin and his coworkers took seven years to determine the pathway, using  $^{14}\text{C}$  in  $\text{CO}_2$  as the tracer and chromatography as the means of separating the products formed after different times of light exposure. Calvin won the Nobel Prize in chemistry in 1961 for this remarkable achievement.

**Physiological Studies** Tracers are used in many studies of physiological function. Some recent studies examine challenges of living in outer space. In an animal study of red blood cell loss during extended space flight, blood plasma volume was measured with  $^{125}\text{I}$ -labeled albumin (a blood protein), and red blood cells labeled with

\*Although this statement is generally correct, differences in isotopic mass *can* influence bond strengths and therefore reaction rates. Such behavior is called a *kinetic isotope effect* and is particularly important for isotopes of hydrogen— $^1\text{H}$ ,  $^2\text{H}$ , and  $^3\text{H}$ —because their masses differ by such large proportions. Section 22.4 discussed how the kinetic isotope effect is employed in the industrial production of heavy water,  $\text{D}_2\text{O}$ .

$^{51}\text{Cr}$  as a trace substitute for Fe were used to assess the survival rate of blood cells. In another study, blood flow in skin under long periods of microgravity was monitored using injected  $^{133}\text{Xe}$ .

**Material Flow** Tracers are used in studies of solid surfaces and the flow of materials. Metal atoms hundreds of layers deep within a solid have been shown to exchange with metal ions from the surrounding solution within a matter of minutes. Chemists and engineers use tracers to study material movement in semiconductor chips, paint, and metal plating, in detergent action, and in the process of corrosion, to mention just a few of many applications.

Hydrologic engineers use tracers to study the volume and flow of large bodies of water. By following radioactive nuclides that formed during atmospheric nuclear bomb tests ( $^3\text{H}$  in  $\text{H}_2\text{O}$ ,  $^{90}\text{Sr}^{2+}$ , and  $^{137}\text{Cs}^+$ ), scientists have mapped the flow of water from land to lakes and streams to oceans. They also use tracers to study the surface and deep ocean currents that circulate around the globe, the mechanisms of hurricane formation, and the mixing of the troposphere and stratosphere.

Various industries employ tracers to study material flow during manufacturing processes, such as the flow of ore pellets in smelting kilns, the paths of wood chips and bleach in paper mills, the diffusion of fungicide into lumber, and in a particularly important application, the porosity and leakage of oil and gas wells in geological formations.

**Activation Analysis** Another use of tracers is in *neutron activation analysis* (NAA). In this method, neutrons bombard a nonradioactive sample, converting a small fraction of its atoms to radioisotopes, which exhibit characteristic decay patterns, such as  $\gamma$ -ray spectra, that reveal the elements present. Unlike chemical analysis, NAA leaves the sample virtually intact, so the method can be used to determine the composition of a valuable object or a very small sample. For example, a painting thought to be a 16<sup>th</sup>-century Dutch masterpiece was shown through NAA to be a 20<sup>th</sup>-century forgery, because a microgram-sized sample of its pigment contained much less silver and antimony than the pigments used by the Dutch masters. Forensic chemists use NAA to detect traces of ammunition on a suspect's hand or traces of arsenic in the hair of a victim of poisoning.

Automotive engineers employ NAA and  $\gamma$ -ray detectors to measure friction and wear of moving parts without having to take an engine apart. For example, when a steel surface that has been neutron-activated to form some radioactive  $^{59}\text{Fe}$  moves against a second steel surface, the amount of radioactivity on the second surface indicates the amount of material rubbing off. The radioactivity appearing in a lubricant placed between the surfaces can demonstrate the lubricant's ability to reduce wear.

**Medical Diagnosis** The largest use of radioisotopes is in medical science. Tracers with half-lives of a few minutes to a few days are employed to observe specific organs and body parts.

For example, a healthy thyroid gland incorporates dietary  $\text{I}^-$  into iodine-containing hormones at a known rate. To assess thyroid function, the patient drinks a solution containing a trace amount of  $\text{Na}^{131}\text{I}$ ; the thyroid gland absorbs  $^{131}\text{I}^-$  ions, which undergo  $\beta^-$  decay, and the emissions produce an image of the gland (Figure 24.13A, *next page*). Technetium-99 ( $Z = 43$ ) is also used for imaging the thyroid (Figure 24.13B, *next page*), as well as the heart, lungs, and liver. Technetium does not occur naturally, so the radioisotope (actually a metastable form,  $^{99\text{m}}\text{Tc}$ ) is prepared from radioactive molybdenum just before use:

Tracers are also used to measure physiological processes, such as blood flow. The rate at which the heart pumps blood, for example, can be observed by injecting  $^{59}\text{Fe}$ , which becomes incorporated into the hemoglobin of blood cells. Several radioisotopes used in medical diagnosis are listed in Table 24.10.

**Some Radioisotopes  
Used as Tracers in  
Medical Diagnosis**

**Table 24.10**

Isotope	Body Part or Process
$^{11}\text{C}$ , $^{18}\text{F}$ , $^{13}\text{N}$ , $^{15}\text{O}$	PET studies of brain, heart
$^{60}\text{Co}$ , $^{192}\text{Ir}$	Cancer therapy
$^{64}\text{Cu}$	Metabolism of copper
$^{59}\text{Fe}$	Blood flow, spleen
$^{67}\text{Ga}$	Tumor imaging
$^{123}\text{I}$ , $^{131}\text{I}$	Thyroid
$^{111}\text{In}$	Brain, colon
$^{42}\text{K}$	Blood flow
$^{81\text{m}}\text{Kr}$	Lung
$^{99\text{m}}\text{Tc}$	Heart, thyroid, liver, lung, bone
$^{201}\text{Tl}$	Heart muscle
$^{90}\text{Y}$	Cancer, arthritis

*Positron-emission tomography (PET)* is a powerful imaging method for observing brain structure and function. A biological substance is synthesized with one of its atoms replaced by an isotope that emits positrons. The substance is injected into a patient's bloodstream, from which it is taken up into the brain. The isotope emits positrons, each of which annihilates a nearby electron. In this process, two  $\gamma$  photons are emitted simultaneously  $180^\circ$  from each other:

An array of detectors around the patient's head pinpoints the sites of  $\gamma$  emission, and the image is analyzed by computer. Two of the isotopes used are  $^{15}\text{O}$ , injected as  $\text{H}_2^{15}\text{O}$  to measure blood flow, and  $^{18}\text{F}$  bonded to a glucose analog to measure glucose uptake, which is an indicator of energy metabolism.

Among many fascinating findings revealed by PET are those that show how changes in blood flow and glucose uptake accompany normal or abnormal brain activity (Figure 24.14). Also, substances incorporating  $^{11}\text{C}$  and  $^{15}\text{O}$  are being investigated using PET to learn how molecules interact with and move along the surface of a catalyst.

**Figure 24.14** PET and brain activity. These PET scans show brain activity in a normal person (*left*) and in a patient with Alzheimer's disease (*right*). Red and yellow indicate relatively high activity within a region.

## Additional Applications of Ionizing Radiation

Many other uses of radioisotopes involve higher-energy ionizing radiation.

1. *Radiation therapy.* Cancer cells divide more rapidly than normal cells, so radioisotopes that interfere with cell division kill more cancer cells than normal ones. Implants of  $^{198}\text{Au}$  or of  $^{90}\text{Sr}$ , which decays to the  $\gamma$ -emitting  $^{90}\text{Y}$ , have been used to destroy pituitary and breast tumor cells, and  $\gamma$  rays from  $^{60}\text{Co}$  have been used to destroy tumors of the brain and other organs.

2. *Destruction of microbes.* Irradiation of food increases shelf life by killing microorganisms that cause rotting or spoilage (Figure 24.15), but the practice is controversial. Advocates point to the benefits of preserving fresh foods, grains, and seeds for

**Figure 24.15** The increased shelf life of irradiated food.

Source: Iowa State University

long periods, whereas opponents suggest that irradiation might lower the food's nutritional content or produce harmful byproducts. Irradiation also provides a way to destroy newer, more resistant bacterial strains that survive the increasing use of the more common antibiotics in animal feed. The United Nations has approved irradiation for potatoes, wheat, chicken, and strawberries, and the U.S. Food and Drug Administration has approved it for these and other food items as well.

3. *Insect control.* Ionizing radiation has been used to control harmful insects. Captured males are sterilized by radiation and released to mate, thereby reducing the number of offspring. This method has been used to control the Mediterranean fruit fly in California and certain disease-causing insects, such as the tsetse fly and malarial mosquito, in other parts of the world.

4. *Power for spacecraft instruments.* A nonharmful use of ionizing radiation relies on its secondary processes. Most spacecraft use solar energy to provide power for instruments. In deep-space missions, when solar energy is too weak, however, a radioisotope heater unit (RHU) has been used. It consists of a  $^{238}\text{PuO}_2$  fuel pellet the size of a pencil eraser that is clad within a multilayered graphite and metal shell a little smaller than a flashlight battery. The whole RHU weighs only 40 g.

### › Summary of Section 24.5

- › Radioisotopic tracers have been used to study reaction mechanisms, material flow, elemental composition, and medical conditions.
- › Ionizing radiation has been used in devices that destroy cancer tissue, kill organisms that spoil food, control insect populations, and power spacecraft instruments.

## 24.6 THE INTERCONVERSION OF MASS AND ENERGY

Most of the nuclear processes we've considered so far have involved radioactive decay, in which a nucleus emits one or a few small particles or photons to become a more stable and, usually, slightly lighter nucleus. Two other nuclear processes cause much greater mass changes. In nuclear **fission**, a heavy nucleus splits into two much lighter nuclei. In nuclear **fusion**, the opposite process occurs: two lighter nuclei combine to form a heavier one. Both fission and fusion release enormous quantities of energy. Let's look at the origins of this energy by examining the change in mass that accompanies the breakup of a nucleus into its nucleons and then determine the energy that is equivalent to this mass change.

### The Mass Difference Between a Nucleus and Its Nucleons

For most of the 20<sup>th</sup> century, we knew that mass and energy are interconvertible. The separate mass and energy conservation laws are combined to state that *the total quantity of mass-energy in the universe is constant*. Therefore, when any reacting system releases or absorbs energy, it also loses or gains mass.

**Mass Difference in Chemical Reactions** The interconversion of mass and energy is not important for chemical reactions because the energy changes involved in breaking or forming chemical bonds are so small that the mass changes are negligible. For example, when 1 mol of water breaks up into its atoms, heat is absorbed and we have:

We find the mass that is equivalent to this energy from *Einstein's equation*:

$$E = mc^2 \quad \text{or} \quad \Delta E = \Delta mc^2 \quad \text{so} \quad \Delta m = \frac{\Delta E}{c^2} \quad (24.7)$$

where  $\Delta m$  is the mass difference between reactants and products:

$$\Delta m = m_{\text{products}} - m_{\text{reactants}}$$

Substituting the enthalpy of reaction (in J/mol) for  $\Delta E$  and the numerical value for  $c$  ( $2.9979 \times 10^8$  m/s), we obtain

$$\Delta m = \frac{9.34 \times 10^5 \text{ J/mol}}{(2.9979 \times 10^8 \text{ m/s})^2} = 1.04 \times 10^{-11} \text{ kg/mol} = 1.04 \times 10^{-8} \text{ g/mol}$$

(Units of kg/mol are obtained because the joule includes the kilogram:  $1 \text{ J} = 1 \text{ kg} \cdot \text{m}^2/\text{s}^2$ .) The mass of 1 mol of  $\text{H}_2\text{O}$  molecules (reactant) is about 10 ng *less* than the combined masses of 2 mol of H atoms and 1 mol of O atoms (products), a change difficult to measure with even the most advanced balance. Such minute mass changes when bonds break or form allow us to assume that, for all practical purposes, mass is conserved in *chemical* reactions.

**Mass Difference in Nuclear Reactions** The much larger mass change that accompanies a *nuclear* process is related to the enormous energy required to bind the nucleons together in a nucleus. In an analogy with the calculation above involving the water molecule, consider the change in mass that occurs when one  $^{12}\text{C}$  nucleus breaks apart into its nucleons—six protons and six neutrons:

We calculate this mass difference in a special way. By combining the mass of six H atoms and six neutrons and then subtracting the mass of one  $^{12}\text{C}$  atom, the masses of the electrons cancel: six  $e^-$  (in six  $^1\text{H}$  atoms) cancel six  $e^-$  (in one  $^{12}\text{C}$  atom). The mass of one  $^1\text{H}$  atom is 1.007825 amu, and the mass of one neutron is 1.008665 amu, so

$$\begin{array}{l} \text{Mass of six } ^1\text{H atoms} = 6 \times 1.007825 \text{ amu} = 6.046950 \text{ amu} \\ \text{Mass of six neutrons} = 6 \times 1.008665 \text{ amu} = 6.051990 \text{ amu} \\ \hline \text{Total mass} = 12.098940 \text{ amu} \end{array}$$

The mass of the reactant, one  $^{12}\text{C}$  atom, is 12 amu (exactly). The mass difference ( $\Delta m$ ) we obtain is the total mass of the nucleons minus the mass of the nucleus:

$$\begin{aligned} \Delta m &= 12.098940 \text{ amu} - 12.000000 \text{ amu} \\ &= 0.098940 \text{ amu}/^{12}\text{C} = 0.098940 \text{ g/mol } ^{12}\text{C} \end{aligned}$$

Two key points emerge from these calculations:

- *The mass of the nucleus is less than the combined masses of its nucleons:* there is *always* a mass decrease when nucleons form a nucleus.
- The mass change of this nuclear process ( $9.89 \times 10^{-2}$  g/mol  $\approx 10 \times 10^{-2}$ , or 0.10 g/mol) is nearly 10 million times what we found earlier for the chemical process of breaking the bonds in water ( $10.4 \times 10^{-9}$  g/mol) and could be measured easily on any laboratory balance.

## Nuclear Binding Energy and Binding Energy per Nucleon

Einstein's equation for the relation between mass and energy allows us to find the energy equivalent of any mass change. For 1 mol of  $^{12}\text{C}$ , after converting grams to kilograms, we have

$$\begin{aligned} \Delta E &= \Delta mc^2 = (9.8940 \times 10^{-5} \text{ kg/mol})(2.9979 \times 10^8 \text{ m/s})^2 \\ &= 8.8921 \times 10^{12} \text{ J/mol} = 8.8921 \times 10^9 \text{ kJ/mol} \end{aligned}$$

This quantity of energy is called the **nuclear binding energy** for carbon-12, and the positive value means *energy is absorbed*. *The nuclear binding energy is the energy required to break 1 mol of nuclei of an element into individual nucleons:*

Thus, the nuclear binding energy is *qualitatively* analogous to the sum of bond energies of a covalent compound or the lattice energy of an ionic compound. But, *quantitatively*, nuclear binding energies are typically several million times greater.

**The Electron Volt as the Unit of Binding Energy** We use joules to express the binding energy per mole of nuclei, but the joule is much too large a unit to express the binding energy of a single nucleus. Instead, nuclear scientists use the **electron**

**volt (eV)**, the energy an electron acquires when it moves through a potential difference of 1 volt:

$$1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}$$

Binding energies are commonly expressed in millions of electron volts, that is, in *mega-electron volts* (MeV):

$$1 \text{ MeV} = 10^6 \text{ eV} = 1.602 \times 10^{-13} \text{ J}$$

A particularly useful factor converts the atomic mass unit to its energy equivalent in electron volts:

$$1 \text{ amu} = 931.5 \times 10^6 \text{ eV} = 931.5 \text{ MeV} \quad (24.8)$$

**Nuclear Stability and Binding Energy per Nucleon** Earlier we found the mass change when  $^{12}\text{C}$  breaks apart into its nucleons to be 0.098940 amu. The binding energy per  $^{12}\text{C}$  nucleus, expressed in MeV, is

$$\frac{\text{Binding energy}}{^{12}\text{C nucleus}} = 0.098940 \text{ amu} \times \frac{931.5 \text{ MeV}}{1 \text{ amu}} = 92.16 \text{ MeV}$$

We can compare the stability of nuclides of different elements by determining the *binding energy per nucleon*. For  $^{12}\text{C}$ , we have

$$\text{Binding energy per nucleon} = \frac{\text{binding energy}}{\text{no. of nucleons}} = \frac{92.16 \text{ MeV}}{12 \text{ nucleons}} = 7.680 \text{ MeV/nucleon}$$

### SAMPLE PROBLEM 24.7

### Calculating the Binding Energy per Nucleon

**Problem** Iron-56 is an extremely stable nuclide. Compute the binding energy per nucleon for  $^{56}\text{Fe}$  and compare it with that for  $^{12}\text{C}$  (mass of  $^{56}\text{Fe}$  atom = 55.934939 amu; mass of  $^1\text{H}$  atom = 1.007825 amu; mass of neutron = 1.008665 amu).

**Plan** Iron-56 has 26 protons and 30 neutrons. We calculate the mass difference,  $\Delta m$ , when the nucleus forms by subtracting the given mass of one  $^{56}\text{Fe}$  atom from the sum of the masses of 26  $^1\text{H}$  atoms and 30 neutrons. To find the binding energy per nucleon, we multiply  $\Delta m$  by the equivalent in MeV (931.5 MeV/amu) and divide by the number of nucleons (56).

**Solution** Calculating the mass difference,  $\Delta m$ :

$$\begin{aligned} \text{Mass difference} &= [(26 \times \text{mass } ^1\text{H atom}) + (30 \times \text{mass neutron})] - \text{mass } ^{56}\text{Fe atom} \\ &= [(26)(1.007825 \text{ amu}) + (30)(1.008665 \text{ amu})] - 55.934939 \text{ amu} \\ &= 0.52846 \text{ amu} \end{aligned}$$

Calculating the binding energy per nucleon:

$$\text{Binding energy per nucleon} = \frac{0.52846 \text{ amu} \times 931.5 \text{ MeV/amu}}{56 \text{ nucleons}} = 8.790 \text{ MeV/nucleon}$$

An  $^{56}\text{Fe}$  nucleus would require more energy per nucleon to break up into its nucleons than would a  $^{12}\text{C}$  nucleus (7.680 MeV/nucleon), so  $^{56}\text{Fe}$  is more stable than  $^{12}\text{C}$ .

**Check** The answer is consistent with the great stability of  $^{56}\text{Fe}$ . Given the number of decimal places in the values, rounding to check the math is useful only to find a *major* error. The number of nucleons (56) is exact, so we retain four significant figures.

### FOLLOW-UP PROBLEMS

**24.7A** Enormous amounts of nickel and iron make up Earth's core, and nickel-58 is a very stable nuclide. Find the binding energy per nucleon for  $^{58}\text{Ni}$  (mass of  $^{58}\text{Ni}$  atom = 57.935346 amu), and compare it with the value for  $^{56}\text{Fe}$  (8.790 MeV/nucleon).

**24.7B** Uranium-235 is an essential component of the fuel in nuclear power plants. Calculate the binding energy per nucleon for  $^{235}\text{U}$  (mass of  $^{235}\text{U}$  atom = 235.043924 amu). Is this nuclide more or less stable than  $^{12}\text{C}$  (whose value is 7.680 MeV/nucleon)?

**SOME SIMILAR PROBLEMS** 24.79–24.82

### Student Hot Spot

Student data indicate that you may struggle with binding energy calculations. Access the Smartbook to view additional Learning Resources on this topic.

**Figure 24.16** The variation in binding energy per nucleon.

**Fission or Fusion: Increasing the Binding Energy per Nucleon** Calculations similar to those in Sample Problem 24.7 for other nuclides show that the binding energy per nucleon varies considerably. The essential point is that *the greater the binding energy per nucleon, the more stable the nuclide is.*

Figure 24.16 shows a plot of the binding energy per nucleon vs. mass number. It provides information about nuclide stability and the two possible processes—fission and fusion—that nuclides undergo to form more stable nuclides. Most nuclides with fewer than 10 nucleons have a relatively small binding energy per nucleon. The  ${}^4\text{He}$  nucleus is an exception—it is stable enough to be emitted intact as an  $\alpha$  particle. Above  $A = 12$ , the binding energy per nucleon varies from about 7.6 to 8.8 MeV.

The most important observation is that *the binding energy per nucleon peaks at elements with  $A \approx 60$ .* In other words, nuclides become more stable with increasing mass number up to around 60 nucleons and then become less stable with higher numbers of nucleons. The existence of a peak of stability suggests that there are two ways nuclides can increase their binding energy per nucleon:

- **Fission.** A heavier nucleus can *split into lighter nuclei (closer to  $A \approx 60$ )* by undergoing fission. The product nuclei have greater binding energy per nucleon (are more stable) than the reactant nucleus, and the difference in energy is released. Nuclear power plants generate energy through fission, as do atomic bombs (Section 24.7).
- **Fusion.** Lighter nuclei, on the other hand, can *combine to form a heavier nucleus (closer to  $A \approx 60$ )* by undergoing fusion. Once again, the product is more stable than the reactants, and energy is released. The Sun and other stars generate energy through fusion, as do thermonuclear (hydrogen) bombs. In these examples and in all current research efforts for developing fusion as a useful energy source, hydrogen nuclei fuse to form the very stable helium-4 nucleus.

In Section 24.7, we examine fission and fusion and their applications.

### › Summary of Section 24.6

- › The mass of a nucleus is less than the sum of the masses of its nucleons. The energy equivalent to this mass difference is the nuclear binding energy, often expressed in units of MeV.
- › The binding energy per nucleon is a measure of nuclide stability and varies with the number of nucleons. Nuclides with  $A \approx 60$  are most stable.
- › Lighter nuclides join (fusion) or heavier nuclides split (fission) to create more stable products.

## 24.7 APPLICATIONS OF FISSION AND FUSION

Of the many beneficial applications of nuclear reactions, the greatest is the potential for abundant quantities of energy, which is based on the multimillion-fold increase in energy yield of nuclear reactions over chemical reactions. Our experience with nuclear

energy from power plants in the last quarter of the 20<sup>th</sup> century, however, has shown that we must improve ways to tap this energy source safely and economically and deal with the waste generated. In this section, we discuss how fission and fusion occur and how we are applying them.

## The Process of Nuclear Fission

During the mid-1930s, Enrico Fermi and coworkers bombarded uranium ( $Z = 92$ ) with neutrons in an attempt to synthesize transuranium elements. Many of the unstable nuclides produced were tentatively identified as having  $Z > 92$ , but other scientists were skeptical. Four years later, the German chemist Otto Hahn and his associate F. Strassmann showed that one of these unstable nuclides was an isotope of barium ( $Z = 56$ ). The Austrian physicist Lise Meitner, a coworker of Hahn, and her nephew Otto Frisch proposed that barium resulted from the *splitting* of the uranium nucleus into *smaller* nuclei, a process that they called *fission* as an analogy to cell division in biology. Element 109 was named *meitnerium* in honor of this extraordinary physicist who proposed the correct explanation of nuclear fission and discovered the element protactinium (Pa;  $Z = 91$ ) as well as numerous radioisotopes.

The  $^{235}\text{U}$  nucleus can split in many different ways, giving rise to various daughter nuclei, but all routes have the same general features. Figure 24.17 depicts *one* of these fission patterns, the production of isotopes of Kr and Ba:

Neutron bombardment results in a highly excited  $^{236}\text{U}$  nucleus, which splits apart in  $10^{-14}$  s. The products are two nuclei of unequal mass, two to four neutrons (average of 2.4), and a large quantity of energy. A single  $^{235}\text{U}$  nucleus releases  $3.5 \times 10^{-11}$  J when it splits; 1 mol of  $^{235}\text{U}$  (about  $\frac{1}{2}$  lb) releases  $2.1 \times 10^{13}$  J—a billion times as much energy as burning  $\frac{1}{2}$  lb of coal ( $2 \times 10^4$  J)!

**Chain Reaction and Critical Mass** We harness the energy of nuclear fission, much of which eventually appears as heat, by means of a **chain reaction** (Figure 24.18, *next page*): the few neutrons that are released by the fission of one nucleus collide with other fissionable nuclei and cause them to split, releasing more neutrons, and so on, in a self-sustaining process (in Figure 24.18, vertical dashed lines separate the steps). In this manner, the energy released increases rapidly because each fission event in a chain reaction releases about two-and-a-half times as much energy as the preceding one.

Whether a chain reaction occurs depends on the mass (and thus the volume) of the fissionable sample. If the piece of uranium is large enough, the product neutrons strike another fissionable nucleus *before* flying out of the sample, and a chain reaction takes place. The mass required to achieve a chain reaction is called the **critical mass**. If the sample has less than the critical mass (a *subcritical mass*), too many product

**Figure 24.17** Fission of  $^{235}\text{U}$  caused by neutron bombardment.

**Figure 24.18** A chain reaction involving fission of  $^{235}\text{U}$ .

neutrons leave the sample before they collide with, and cause the fission of, another  $^{235}\text{U}$  nucleus, and thus a chain reaction does not occur.

**Uncontrolled Fission: The Atomic Bomb** An uncontrolled chain reaction can be adapted to make an extremely powerful explosive, as several of the world's leading atomic physicists hypothesized just prior to World War II. In August 1939, Albert Einstein wrote the president of the United States, Franklin Delano Roosevelt, to this effect, warning of the danger of allowing the Nazi government of Germany to develop this power first. It was this concern that led to the Manhattan Project, an enormous scientific effort to develop a bomb based on nuclear fission, which was initiated in 1941.\* In August 1945, the United States detonated two atomic bombs over Japan, and the horrible destructive power of these bombs was a major factor in the surrender of the Japanese a few days later.

In an atomic bomb, small explosions of trinitrotoluene (TNT) bring subcritical masses of fissionable material together to exceed the critical mass, and the ensuing chain reaction brings about the explosion (Figure 24.19). The proliferation of nuclear power plants, which use fissionable materials to generate energy for electricity, has increased concern that more countries (and unscrupulous individuals) may have access to such material for making bombs. Since the devastating terrorist attacks of September 11, 2001 in the United States, this concern has been heightened.

**Controlled Fission: Nuclear Energy Reactors** Like a coal-fired power plant, a nuclear power plant generates heat to produce steam, which turns a turbine attached to an electric generator. But a nuclear plant has the potential to produce electric power much more cleanly than by the combustion of coal.

1. *Operation of a nuclear power plant.* Heat generation takes place in the **reactor core** of a nuclear plant (Figure 24.20). The core contains the **fuel rods**, which consist

\*For an excellent scientific and historical account of the development of the atomic bomb, see R. Rhodes, *The Making of the Atomic Bomb*, New York, Simon and Schuster, 1986.

**Figure 24.19** An atomic bomb based on  $^{235}\text{U}$ .

**Figure 24.20** A light-water nuclear reactor.

Source: © Philip Lange/Shutterstock.com

of fuel enclosed in tubes of a corrosion-resistant zirconium alloy. The fuel is uranium(IV) oxide ( $\text{UO}_2$ ) that has been *enriched* from 0.7%  $^{235}\text{U}$ , the natural abundance of this fissionable isotope, to the 3% to 4%  $^{235}\text{U}$  required to sustain a chain reaction in a practical volume. (Enrichment of nuclear fuel is the most important application of Graham's law; see Section 5.5.) Sandwiched between the fuel rods are movable *control rods* made of cadmium or boron (or, in nuclear submarines, hafnium), substances that absorb neutrons very efficiently. For example, a neutron absorption reaction for boron is

When the control rods are lowered between the fuel rods, the chain reaction slows because fewer neutrons are available to bombard uranium atoms; when they are raised, the chain reaction speeds up. Neutrons that leave the fuel-rod assembly collide with a *reflector*, usually made of a beryllium alloy, which absorbs very few neutrons. Reflecting the neutrons back to the fuel rods speeds the chain reaction.

Flowing around the fuel and control rods in the reactor core is the *moderator*, a substance that slows the neutrons, making them much better at causing fission than the fast ones emerging directly from the fission event. In most modern reactors, the

moderator also acts as the *coolant*, the fluid that transfers the released heat to the steam-producing region. *Light-water reactors* use  $\text{H}_2\text{O}$  as the moderator because  $^1\text{H}$  absorbs neutrons to some extent; in heavy-water reactors,  $\text{D}_2\text{O}$  is used. The advantage of  $\text{D}_2\text{O}$  is that it absorbs very few neutrons, leaving more available for fission, so heavy-water reactors can use uranium that has been *less enriched*. As the coolant flows around the encased fuel, pumps circulate it through coils that transfer its heat to the water reservoir. Steam formed in the reservoir turns the turbine that runs the generator. The steam then enters a condenser, where water from a lake or river is used to cool it back to liquid that is returned to the water reservoir. Often (although not shown here), large cooling towers aid in this step (see Figure 13.20).

2. *Breeder reactors.* Because  $^{235}\text{U}$  is not an abundant isotope, the *breeder reactor* was designed to consume one type of nuclear fuel as it produces another. Outside the moderator, fuel rods are surrounded by natural  $\text{U}_3\text{O}_8$ , which contains 99.3% *nonfissionable*  $^{238}\text{U}$  atoms. As neutrons formed during  $^{235}\text{U}$  fission escape the fuel rod, they collide with  $^{238}\text{U}$ , transmuted it into  $^{239}\text{Pu}$ , another fissionable nucleus:

Although breeder reactors can make fuel as they operate, they are difficult and expensive to build, and  $^{239}\text{Pu}$  is extremely toxic and long lived. Breeder reactors are not used in the United States, although several are operating in Europe and Asia.

3. *Power plant accidents and other concerns.* Some major accidents at nuclear plants have caused decidedly negative public reactions. In 1979, malfunctions of coolant pumps and valves at the Three-Mile Island facility in Pennsylvania led to melting of some of the fuel and damage to the reactor core, but the release of only a very small amount (about 1 Ci) of radioactive gases into the atmosphere. In 1986, a million times as much radioactivity (1 MCi) was released when a cooling system failure at the Chernobyl plant in Ukraine caused a much greater melting of fuel and an uncontrolled reaction. High-pressure steam and ignited graphite moderator rods caused the reactor building to explode and expel radioactive debris. Carried by prevailing winds, the radioactive particles contaminated vegetables and milk in much of Europe. Severe health problems have resulted.\* And, in 2011, an earthquake and subsequent tsunami caused vast destruction in northern Japan, affecting the Fukushima Dai-ichi nuclear facility and causing the breakdown of cooling-water pumps and the melting of three reactor cores. Large amounts of radioactive steam were released into the air, and radioactive water is still entering the sea, with serious, long-term health effects expected.

4. *Current use of nuclear power.* Despite potential safety problems, nuclear power remains an important source of electricity. In the late 1990s, nearly every European country employed nuclear power, and it is the major power source in some countries—Sweden creates 50% of its electricity this way and France almost 80%. Currently, the United States obtains about 20% of its electricity from nuclear power, and Canada slightly less. As our need for energy grows and climate change from fossil-fuel consumption worsens, safer reactors will be designed and built. However, as a result of the disaster in Japan, many countries are reevaluating their use of nuclear energy. For example, Germany has committed to closing all its nuclear power plants by 2022.

5. *Thermal pollution and waste disposal.* Even a smoothly operating nuclear power plant has certain inherent problems. The problem of *thermal pollution* is common to all power plants. Water used to condense the steam is several degrees warmer when returned to its source, which can harm aquatic organisms (Section 13.4). A more serious problem

\*An even greater release of radioactivity (1.1 MCi), involving several radioisotopes including the extremely dangerous  $^{90}\text{Sr}$ , occurred in 1957 in Kyshtym, a town in the South Ural Mountains of Russia. As a result, radioactivity spread globally, but the accident was kept secret by the former Soviet government until 1980.

is *nuclear waste disposal*. Many of the fission products formed in nuclear reactors have long half-lives, and no satisfactory plan for their permanent disposal has yet been devised. Proposals to place the waste in containers and bury them in deep bedrock cannot possibly be field-tested for the thousands of years the material will remain harmful. Leakage of radioactive material into groundwater is a danger, and earthquakes can occur even in geologically stable regions. It remains to be seen whether we can operate fission reactors *and* dispose of the waste safely and economically.

## The Promise of Nuclear Fusion

Nuclear fusion in the Sun is the ultimate source of nearly all the energy—and chemical elements—on Earth. In fact, *all the elements heavier than hydrogen were formed in fusion and decay processes within stars*, as the upcoming Chemical Connections essay describes.

Much research is being devoted to making nuclear fusion a practical, direct source of energy on Earth. To understand the advantages of fusion, let's consider one of the most discussed fusion reactions, in which deuterium and tritium react:

This reaction produces  $1.7 \times 10^9$  kJ/mol, an enormous quantity of energy with no radioactive byproducts. Moreover, the reactant nuclei are relatively easy to come by. We obtain deuterium from the electrolysis of water (Section 22.4). In nature, tritium forms through the cosmic (neutron) irradiation of  ${}^{14}\text{N}$ :

However, this process results in a natural abundance of only  $10^{-7}\%$   ${}^3\text{H}$ . More practically, tritium is produced in nuclear accelerators by bombarding lithium-6 or by surrounding the fusion reactor itself with material containing lithium-6:

Thus, in principle, fusion *seems* promising and may represent an ideal source of power. However, some extremely difficult technical problems remain. Fusion requires enormous energy in the form of heat to give the positively charged nuclei enough kinetic energy to force themselves together. The fusion of deuterium and tritium, for example, occurs at practical rates at about  $10^8$  K, a temperature hotter than the Sun's core! How can such conditions be achieved?

Two current research approaches have promise. In one, atoms are stripped of their electrons at high temperatures, which results in a gaseous *plasma*, a neutral mixture of positive nuclei and electrons. Because of the extreme temperatures needed for fusion, no *material* can contain the plasma. The most successful approach to date has been to enclose the plasma within a magnetic field. The *tokamak* design has a donut-shaped container in which a helical magnetic field confines the plasma and prevents it from contacting the walls (Figure 24.21). Scientists at the Princeton University Plasma Physics facility have achieved some success in generating energy from fusion this way. In another approach, the required high temperature is reached by using many focused lasers to compress and heat the fusion reactants. In any event, one or more major breakthroughs are needed before fusion will be a practical, everyday source of energy.

### › Summary of Section 24.7

- › In nuclear fission, neutron bombardment causes a nucleus to split into two smaller nuclei and release neutrons that split other nuclei, giving rise to a chain reaction.
- › A nuclear power plant controls the rate of the chain reaction to produce heat that creates steam, which is used to generate electricity.
- › Potential hazards, such as radiation leaks, thermal pollution, and disposal of nuclear waste, remain current concerns.
- › Nuclear fusion holds great promise as a source of clean abundant energy, but it requires extremely high temperatures and is not yet practical.
- › The elements were formed through a complex series of nuclear reactions in evolving stars.

**Figure 24.21** The tokamak design for magnetic containment of a fusion plasma.

Source: Dietmar Krause/Princeton Plasma Physics Lab

**H**ow did the universe begin? Where did matter come from? How were the elements formed? The most accepted model proposes that a sphere of unimaginable properties—diameter of  $10^{-28}$  cm, density of  $10^{96}$  g/mL (density of a nucleus  $\approx 10^{14}$  g/mL), and temperature of  $10^{32}$  K—exploded in a “Big Bang,” for reasons not yet known, and distributed its contents through the void of space. Cosmologists consider this moment the beginning of time.

One second later, the universe was an expanding mixture of neutrons, protons, and electrons, denser than rock and hotter than an exploding hydrogen bomb (about  $10^{10}$  K). In the next few minutes, it became a gigantic fusion reactor creating the first atomic nuclei other than  $^1\text{H}$ :  $^2\text{H}$ ,  $^3\text{He}$ , and  $^4\text{He}$ . After 10 min, more than 25% of the mass of the universe existed as  $^4\text{He}$ , and only about 0.025% as  $^2\text{H}$ . About 100 million years later, or almost 14 billion years ago, gravitational forces pulled this cosmic mixture into primitive, contracting stars.

This account of the origin of the universe is based on the observation of spectra from the Sun, other stars, nearby galaxies, and cosmic (interstellar) dust. Spectral analysis of planets and chemical analysis of Earth and Moon rocks, meteorites, and cosmic-ray particles furnish data about isotope abundance. From these, a model has been developed for **stellar nucleosynthesis**,

the creation of the elements in stars. The overall process occurs in several stages during a star’s evolution, and the entire sequence of steps occurs only in very massive stars, having 10 to 100 times the mass of the Sun. Each step involves a contraction of the volume of the star that results in higher temperature and yields heavier nuclei. Such events are forming elements in stars today. The key stages in the process are shown in Figure B24.1 and described below:

1. *Hydrogen burning produces He.* The initial contraction of a star heats its core to about  $10^7$  K, at which point a fusion process called *hydrogen burning* begins. Through three possible reactions (one is shown below), helium nuclei are produced from the abundant protons:

2. *Helium burning produces C, O, Ne, and Mg.* After several billion years of hydrogen burning, about 10% of the  $^1\text{H}$  is consumed, and the star contracts further. The  $^4\text{He}$  forms a dense core, hot enough ( $2 \times 10^8$  K) to fuse  $^4\text{He}$  nuclei. The energy released during *helium burning* expands the remaining  $^1\text{H}$  into a vast envelope: the star becomes a *red giant*, more than 100 times its original diameter. Within its core, pairs of  $^4\text{He}$  nuclei ( $\alpha$  particles) fuse into

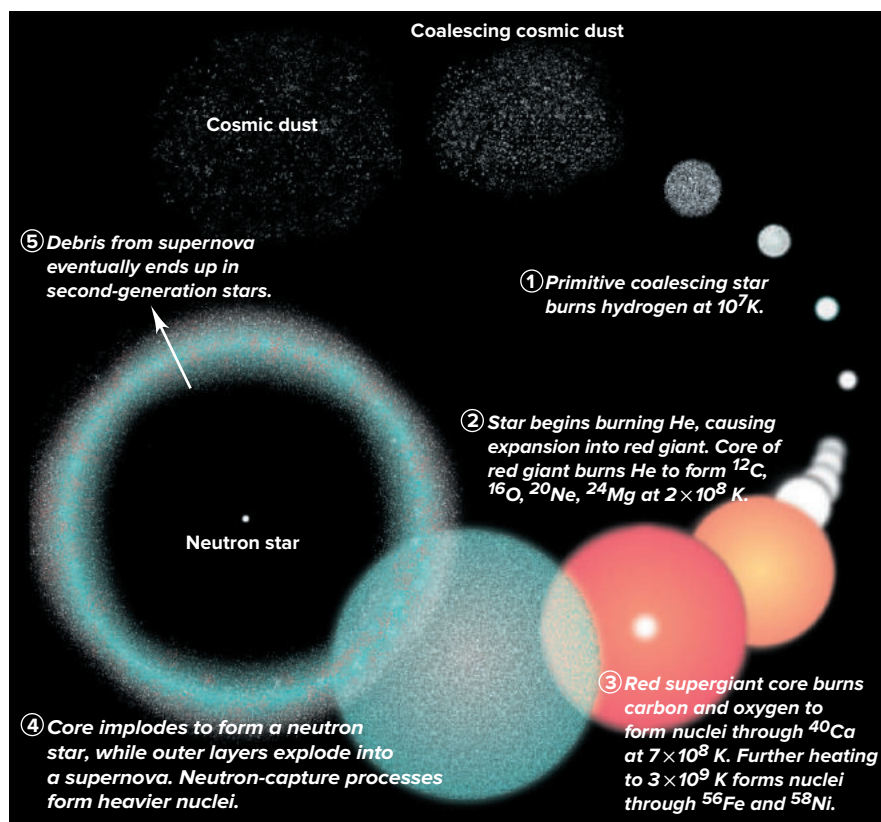

Figure B24.1 Element synthesis in the life cycle of a star.

unstable  ${}^8\text{Be}$  nuclei ( $t_{1/2} = 7 \times 10^{-17}$  s), which play the role of an activated complex in chemical reactions. A  ${}^8\text{Be}$  nucleus collides with another alpha particle to form  ${}^{12}\text{C}$ . Then, further fusion with more alpha particles creates nuclei up to  ${}^{24}\text{Mg}$ :

3. *Elements through Fe and Ni form.* For another 10 million years,  ${}^4\text{He}$  is consumed, and the heavier nuclei created form a core. This core contracts and heats, expanding the star into a *supergiant*. Within the hot core ( $7 \times 10^8$  K), *carbon and oxygen burning* occur:

Absorption of  $\alpha$  particles forms nuclei up to  ${}^{40}\text{Ca}$ :

Further contraction and heating to a temperature of  $3 \times 10^9$  K allow reactions in which nuclei release neutrons, protons, and  $\alpha$  particles and then recapture them. As a result, nuclei with lower binding energies supply nucleons to create those with higher binding energies. In stars of moderate mass, less than 10 times the mass of the Sun, this process stops at iron-56 and nickel-58, the nuclei with the highest binding energies.

4. *Heavier elements form.* In very massive stars, the next stage is the most spectacular. With all the fuel consumed, the core collapses within a second. Many Fe and Ni nuclei break down into neutrons and protons. Protons capture electrons to form neutrons, and the entire core forms an incredibly dense *neutron star*. (An Earth-sized star that became a neutron star would fit in the Houston Astrodome!) As the core implodes, the outer layers explode in a *supernova*, which expels material throughout space. A supernova

occurs an average of every few hundred years in each galaxy or once every second somewhere in the universe. The heavier elements are formed during supernova events and are found in *second-generation stars*, those that coalesce from interstellar  ${}^1\text{H}$  and  ${}^4\text{He}$  and the debris of exploded first-generation stars.

Heavier elements form through *neutron-capture* processes. In the *s-process* (*slow* neutron-capture process), a nucleus captures a neutron, at some point over a period of 10 to 1000 years. If the resulting nucleus is unstable, it undergoes  $\beta^-$  decay to form the next element, as in this conversion of  ${}^{68}\text{Zn}$  to  ${}^{70}\text{Ge}$ :

The stable isotopes of most heavy elements up to  ${}^{209}\text{Bi}$  form by the s-process.

Less stable isotopes and those with  $A$  greater than 230 cannot form by the s-process because their half-lives are too short. These form by the *r-process* (*rapid* neutron-capture process) during the fury of the supernova. Many neutron captures, followed by many  $\beta^-$  decays, occur in a second, as when  ${}^{56}\text{Fe}$  is converted to  ${}^{79}\text{Br}$ :

We know from the heavy elements present in the Sun that it is at least a second-generation star presently undergoing hydrogen burning. Together with its planets, it was formed from the dust of exploded stars about  $4.6 \times 10^9$  years ago. This means that many of the atoms on Earth, including some within you, came from exploded stars and are older than the Solar System itself!

Any theory of element formation must be consistent with the element abundances we observe (Section 22.1). Although local compositions, such as those of Earth and the Sun, differ, and mineral grains in meteorites may have abnormal isotopic compositions, large regions of the universe have, on average, similar compositions. Scientists believe element forming reaches a dynamic equilibrium, resulting in *relatively constant amounts of the isotopes*.

## Problems

**B24.1** Compare the s- and r-processes of stellar nucleosynthesis in terms of rate, number of neutrons absorbed, and types of isotopes formed.

**B24.2** The overall reaction taking place during hydrogen burning in a young star is

How much energy (in MeV) is released per He nucleus formed? Per mole of He formed? (Mass of  ${}_1^1\text{H}$  atom = 1.007825 amu; mass of  ${}_2^4\text{He}$  atom = 4.00260 amu; mass of positron =  $5.48580 \times 10^{-4}$  amu.)

**B24.3** Cosmologists modeling the origin of the elements postulate nuclides with very short half-lives. One of these

short-lived nuclides,  ${}^8\text{Be}$  ( $t_{1/2} = 7 \times 10^{-17}$  s), is thought to play a key role in stellar nucleosynthesis by fusing with  ${}^4\text{He}$  to form  ${}^{12}\text{C}$ . Another model proposes the simultaneous fusion of three  ${}^4\text{He}$  nuclei to form  ${}^{12}\text{C}$ . Comment on the validity of this alternative mechanism.

**B24.4** The s-process produces isotopes of elements up to  ${}^{209}\text{Bi}$ . This process is terminated when  ${}^{209}\text{Bi}$  captures a neutron to produce  ${}^{210}\text{Bi}$ , which subsequently undergoes  $\beta^-$  decay to produce nuclide A, which then decays by emitting an  $\alpha$  particle to form nuclide B. This nuclide captures three neutrons to produce nuclide C, which undergoes  $\beta^-$  decay to produce nuclide D, starting the cycle again. Write balanced nuclear equations for the formation of nuclides A through D.

## CHAPTER REVIEW GUIDE

## Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

- How nuclear changes differ, in general, from chemical changes (§24.1)
- The meanings of *radioactivity*, *nucleon*, *nuclide*, and *isotope* (§24.1)
- Characteristics of three types of radioactive emissions:  $\alpha$ ,  $\beta$ , and  $\gamma$  (§24.1)
- The various modes of radioactive decay and how each changes the values of  $A$  and  $Z$  (§24.1)
- How the  $N/Z$  ratio, the even-odd nature of  $N$  and  $Z$ , and magic numbers correlate with nuclear stability (§24.1)
- How an unstable nuclide's mass number or  $N/Z$  ratio correlates with its mode of decay (§24.1)
- How a decay series combines numerous decay steps and ends with a stable nuclide (§24.1)
- How ionization and scintillation counters detect and measure radioactivity (§24.2)
- Why radioactive decay is a first-order process; the meanings of *decay rate* and *specific activity* (§24.2)
- The meaning of *half-life* in the context of radioactive decay (§24.2)
- How the specific activity of an isotope in an object is used to determine the object's age (§24.2)
- How particle accelerators and reactors are used to synthesize new nuclides (§24.3)
- The units of radiation dose; the effects on living tissue of various dosage levels; the inverse relationship between the mass and charge of an emission and its penetrating power (§24.4)
- How ionizing radiation creates free radicals that damage tissue; sources and risks of ionizing radiation (§24.4)
- How radioisotopes are used in research, analysis, and medical diagnosis (§24.5)

- Why the mass of a nucleus is less than the total mass of its nucleons and how this mass difference is related to the nuclear binding energy (§24.6)
- How nuclear stability is related to binding energy per nucleon (§24.6)
- How heavy nuclides undergo fission and lighter ones undergo fusion to increase the binding energy per nucleon (§24.6)
- The current application of fission and potential application of fusion to produce energy (§24.7)

## Master These Skills

- Expressing the mass and charge of a particle with the  ${}^A_ZX$  notation (§24.1; see also §2.5)
- Using changes in the values of  $A$  and  $Z$  to write and balance nuclear equations (SP 24.1)
- Using the  $N/Z$  ratio, the even-odd nature of  $N$  and  $Z$ , and the presence of magic numbers to predict nuclear stability (SP 24.2)
- Using the atomic mass of the element to predict the mode of decay of an unstable nuclide and checking the prediction with the  $N/Z$  ratio (SP 24.3)
- Converting units of radioactivity (§24.2)
- Calculating specific activity, decay constant, half-life, and number of radioactive nuclei (§24.2 and SPs 24.4 and 24.5)
- Estimating the age of an object from the specific activity and half-life of carbon-14 (SP 24.6)
- Writing notations for nuclear transmutations (§24.3)
- Calculating radiation dose and converting units (§24.4)
- Calculating the mass difference between a nucleus and its nucleons and the energy equivalent (§24.6)
- Calculating the binding energy per nucleon and using it to compare stabilities of nuclides (SP 24.7)

## Key Terms

Page numbers appear in parentheses.

activity ( $\mathcal{A}$ ) (1084)	decay (disintegration) series (1082)	half-life ( $t_{1/2}$ ) (1086)	radioisotopic dating (1087)
alpha ( $\alpha$ ) decay (1077)	deuteron (1091)	ionization (1093)	rad (radiation-absorbed dose) (1094)
alpha ( $\alpha$ ) particle (1075)	electron ( $e^-$ ) capture (EC) (1077)	ionizing radiation (1093)	reactor core (1106)
background radiation (1095)	electron volt (eV) (1102)	isotope (1074)	rem (roentgen equivalent for man) (1094)
band of stability (1079)	fission (1101)	nuclear binding energy (1102)	scintillation counter (1083)
becquerel (Bq) (1084)	free radical (1095)	nuclear transmutation (1090)	sievert (Sv) (1094)
beta ( $\beta$ ) decay (1077)	fusion (1101)	nucleon (1074)	stellar nucleosynthesis (1110)
$\beta^-$ decay (1077)	gamma ( $\gamma$ ) emission (1078)	nuclide (1074)	strong force (1080)
beta ( $\beta$ ) particle (1075)	gamma ray ( $\gamma$ ) (1075)	particle accelerator (1091)	tracer (1098)
chain reaction (1105)	Geiger-Müller counter (1083)	positron (1077)	transuranium element (1092)
critical mass (1105)	gray (Gy) (1094)	positron ( $\beta^+$ ) emission (1077)	
curie (Ci) (1084)		radioactivity (1073)	
decay constant (1085)		radioisotope (1087)	

## Key Equations and Relationships

Page numbers appear in parentheses.

24.1 Balancing a nuclear equation (1075):

$$\sum_{\text{Total}} \frac{A}{Z} \text{Reactants} = \sum_{\text{Total}} \frac{A}{Z} \text{Products}$$

24.2 Expressing the decay rate (activity) for radioactive nuclei (1085):

$$\text{Decay rate } (\mathcal{A}) = -\frac{\Delta \mathcal{N}}{\Delta t} = k\mathcal{N}$$

**24.3** Finding the number of nuclei remaining after a given time,  $\mathcal{N}_t$  (1086):

$$\ln \frac{\mathcal{N}_t}{\mathcal{N}_0} = -kt \quad \text{or} \quad \mathcal{N}_t = \mathcal{N}_0 e^{-kt}$$

**24.4** Finding the half-life of a radioactive nuclide (1086):

$$t_{1/2} = \frac{\ln 2}{k}$$

**24.5** Calculating the time to reach a given specific activity (age of an object in radioisotopic dating) (1088):

$$t = \frac{1}{k} \ln \frac{\mathcal{A}_0}{\mathcal{A}_t}$$

**24.6** Writing a transmutation in shorthand notation (1090):

reactant nucleus (particle in, particle(s) out) product nucleus

**24.7** Adapting Einstein's equation to calculate mass difference and/or nuclear binding energy (1101):

$$\Delta m = \frac{\Delta E}{c^2} \quad \text{or} \quad \Delta E = \Delta mc^2$$

**24.8** Relating the atomic mass unit to its energy equivalent in MeV (1103):

$$1 \text{ amu} = 931.5 \times 10^6 \text{ eV} = 931.5 \text{ MeV}$$

### BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

**24.2A** (a) Stable. Like many light nuclides (those with  $Z < 20$ ) for which  $N = Z$ , this one ( $Z = 5$ ) is stable (one of four stable nuclides with both an odd  $Z$  and an odd  $N$ ). (b) Radioactive. This nuclide has both odd  $N$  (35) and odd  $Z$  (23) and  $N/Z = 1.52$ , which is too high for this region of the band of stability.

**24.2B**  ${}^{31}\text{P}$  has an even  $N$  (16), but  ${}^{30}\text{P}$  has both  $N$  and  $Z$  odd.  ${}^{31}\text{P}$  also has a slightly higher  $N/Z$  ratio that is closer to the band of stability.

**24.3A** (a) Iron (Fe) has an atomic mass of 55.85 amu. The  $A$  value of 61 is higher:  $\beta^-$  decay. (b)  $Z > 83$ , which is too high for stability:  $\alpha$  decay will occur.

**24.3B** (a) Titanium's atomic mass is 47.87 amu, which is much higher than the  $A$  value of 40; this nuclide most likely decays by electron capture or  $\beta^+$  emission. (b) Cobalt's atomic mass is 58.93 amu, which is much lower than the  $A$  value of 65; it will probably undergo  $\beta^-$  decay.

Specific activity (Ci/g) =  $1.53 \times 10^{11} \text{ d/s}$

$$\times \frac{1 \text{ Ci}}{3.70 \times 10^{10} \text{ d/s}} \times \frac{1}{2.6 \times 10^{-6} \text{ g}}$$

$$= 1.6 \times 10^6 \text{ Ci/g}$$

(b) Specific activity (Bq/g) =  $1.53 \times 10^{11} \text{ d/s}$

$$\times \frac{1 \text{ Bq}}{1 \text{ d/s}} \times \frac{1}{2.6 \times 10^{-6} \text{ g}}$$

$$= 5.9 \times 10^{16} \text{ Bq/g}$$

**24.4B**  $k = \frac{\mathcal{A} \text{ (nuclei/h)}}{\mathcal{N} \text{ (nuclei)}}$

$$= \frac{9.97 \times 10^{12} \text{ nuclei/h}}{(6.50 \times 10^{-2} \text{ mol})(6.022 \times 10^{23} \text{ nuclei/mol})}$$

$$= 2.55 \times 10^{-10} \text{ h}^{-1}$$

**24.5A**  $\ln \mathcal{A}_t = -kt + \ln \mathcal{A}_0$

$$= -\left(\frac{\ln 2}{15 \text{ h}} \times 4.0 \text{ days} \times \frac{24 \text{ h}}{1 \text{ day}}\right) + \ln (2.5 \times 10^9 \text{ d/s})$$

$$= 17.20$$

$$\mathcal{A}_t = 3.0 \times 10^7 \text{ d/s}$$

**24.5B**  $\mathcal{A}_0 = 5.6 \times 10^{-6} \text{ Ci} \times \frac{3.70 \times 10^{10} \text{ d/s}}{1 \text{ Ci}} = 2.1 \times 10^5 \text{ d/s}$

$$\ln \mathcal{A}_t = -kt + \ln \mathcal{A}_0$$

$$= -\left(\frac{\ln 2}{44.5 \text{ days}} \times 17 \text{ days}\right) + \ln (2.1 \times 10^5 \text{ d/s})$$

$$= -0.265 + 12.25 \text{ d/s} = 11.99 \text{ d/s}$$

$$\mathcal{A}_t = 1.6 \times 10^5 \text{ d/s}$$

$$\text{Fraction decayed} = \frac{2.1 \times 10^5 \text{ d/s} - 1.6 \times 10^5 \text{ d/s}}{2.1 \times 10^5 \text{ d/s}} = 0.23$$

**24.6A**  $t = \frac{1}{k} \ln \frac{\mathcal{A}_0}{\mathcal{A}_t} = \frac{5730 \text{ yr}}{\ln 2} \ln \left(\frac{15.3 \text{ d/min} \cdot \text{g}}{9.41 \text{ d/min} \cdot \text{g}}\right)$

$$= 4.02 \times 10^3 \text{ yr}$$

The mummy case is about 4000 years old.

**24.6B**  $t = \frac{1}{k} \ln \frac{\mathcal{A}_0}{\mathcal{A}_t} = \frac{5730 \text{ yr}}{\ln 2} \ln \left(\frac{15.3 \text{ d/min} \cdot \text{g}}{12.87 \text{ d/min} \cdot \text{g}}\right) = 1430 \text{ yr}$

**24.7A**  ${}^{58}\text{Ni}$  has 28  ${}^1_0\text{p}$  and 30  ${}^1_0\text{n}$ .

$$\Delta m = [(28 \times 1.007825 \text{ amu}) + (30 \times 1.008665 \text{ amu})]$$

$$- 57.935346 \text{ amu}$$

$$= 0.543704 \text{ amu}$$

$$\frac{\text{Binding energy}}{\text{nucleon}} = \frac{0.543704 \text{ amu} \times \frac{931.5 \text{ MeV}}{1 \text{ amu}}}{58 \text{ nucleons}}$$

$$= 8.732 \text{ MeV/nucleon}$$

Therefore,  ${}^{56}\text{Fe}$  (8.790 MeV/nucleon) is slightly more stable than  ${}^{58}\text{Ni}$ .

**24.7B**  ${}^{235}\text{U}$  has 92  ${}^1_0\text{p}$  and 143  ${}^1_0\text{n}$ .

$$\Delta m = [(92 \times 1.007825 \text{ amu}) + (143 \times 1.008665 \text{ amu})]$$

$$- 235.043924 \text{ amu}$$

$$= 1.9151 \text{ amu}$$

$$\frac{\text{Binding energy}}{\text{nucleon}} = \frac{1.9151 \text{ amu} \times \frac{931.5 \text{ MeV}}{1 \text{ amu}}}{235 \text{ nucleons}}$$

$$= 7.591 \text{ MeV/nucleon}$$

Therefore,  ${}^{235}\text{U}$  is less stable than  ${}^{12}\text{C}$  (7.680 MeV/nucleon).

## PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

### Radioactive Decay and Nuclear Stability

(Sample Problems 24.1 to 24.3)

#### Concept Review Questions

**24.1** How do chemical and nuclear reactions differ in

- Magnitude of the energy change?
- Effect on rate of increasing temperature?
- Effect on rate of higher reactant concentration?
- Effect on yield of higher reactant concentration?

**24.2** Sulfur has four naturally occurring stable isotopes. The one with the lowest mass number is sulfur-32, which is also the most abundant (95.02%).

- What percentage of the S atoms in a matchhead are  $^{32}\text{S}$ ?
- The isotopic mass of  $^{32}\text{S}$  is 31.972070 amu. Is the atomic mass of S larger, smaller, or equal to this mass? Explain.

**24.3** What led Marie Curie to draw the following conclusions?

- Radioactivity is a property of the element and not the compound in which it is found. (b) A highly radioactive element, aside from uranium, occurs in pitchblende.

**24.4** Which of the following processes produce an atom of a *different* element: (a)  $\alpha$  decay; (b)  $\beta^-$  decay; (c)  $\gamma$  emission; (d)  $\beta^+$  emission; (e)  $e^-$  capture? Show how  $Z$  and  $N$  change, if at all, with each process.

**24.5** Why is  $^3\text{He}$  stable, but  $^2\text{He}$  has never been detected?

**24.6** How do the modes of decay differ for a neutron-rich nuclide and a proton-rich nuclide?

**24.7** Why might it be difficult to use only a nuclide's  $N/Z$  ratio to predict whether it will decay by  $\beta^+$  emission or by  $e^-$  capture? What other factor is important?

#### Skill-Building Exercises (grouped in similar pairs)

**24.8** Write balanced nuclear equations for the following:

- Alpha decay of  $^{234}_{92}\text{U}$
- Electron capture by neptunium-232
- Positron emission by  $^{12}_7\text{N}$

**24.9** Write balanced nuclear equations for the following:

- $\beta^-$  decay of sodium-26
- $\beta^-$  decay of francium-223
- Alpha decay of  $^{212}_{83}\text{Bi}$

**24.10** Write balanced nuclear equations for the following:

- $\beta^-$  emission by magnesium-27
- $\beta^+$  emission by  $^{23}_{12}\text{Mg}$
- Electron capture by  $^{103}_{46}\text{Pd}$

**24.11** Write balanced nuclear equations for the following:

- $\beta^-$  decay of silicon-32
- Alpha decay of polonium-218
- Electron capture by  $^{110}_{49}\text{In}$

**24.12** Write balanced nuclear equations for the following:

- Formation of  $^{48}_{22}\text{Ti}$  through positron emission
- Formation of silver-107 through electron capture
- Formation of polonium-206 through  $\alpha$  decay

**24.13** Write balanced nuclear equations for the following:

- Formation of  $^{241}_{95}\text{Am}$  through  $\beta^-$  decay
- Formation of  $^{228}_{89}\text{Ac}$  through  $\beta^-$  decay
- Formation of  $^{203}_{83}\text{Bi}$  through  $\alpha$  decay

**24.14** Write balanced nuclear equations for the following:

- Formation of  $^{186}\text{Ir}$  through electron capture
- Formation of francium-221 through  $\alpha$  decay
- Formation of iodine-129 through  $\beta^-$  decay

**24.15** Write balanced nuclear equations for the following:

- Formation of  $^{52}\text{Mn}$  through positron emission
- Formation of polonium-215 through  $\alpha$  decay
- Formation of  $^{81}\text{Kr}$  through electron capture

**24.16** Which nuclide(s) would you predict to be stable? Why?

- $^{20}_8\text{O}$
- $^{59}_{27}\text{Co}$
- $^9_3\text{Li}$

**24.17** Which nuclide(s) would you predict to be stable? Why?

- $^{146}_{60}\text{Nd}$
- $^{114}_{48}\text{Cd}$
- $^{88}_{42}\text{Mo}$

**24.18** Which nuclide(s) would you predict to be stable? Why?

- $^{127}\text{I}$
- tin-106
- $^{68}\text{As}$

**24.19** Which nuclide(s) would you predict to be stable? Why?

- $^{48}\text{K}$
- $^{79}\text{Br}$
- argon-32

**24.20** What is the most likely mode of decay for each nuclide?

- $^{238}_{92}\text{U}$
- $^{48}_{24}\text{Cr}$
- $^{50}_{25}\text{Mn}$

**24.21** What is the most likely mode of decay for each nuclide?

- $^{111}_{47}\text{Ag}$
- $^{41}_{17}\text{Cl}$
- $^{110}_{44}\text{Ru}$

**24.22** What is the most likely mode of decay for each nuclide?

- $^{15}\text{C}$
- $^{120}\text{Xe}$
- $^{224}\text{Th}$

**24.23** What is the most likely mode of decay for each nuclide?

- $^{106}\text{In}$
- $^{141}\text{Eu}$
- $^{241}\text{Am}$

**24.24** Why is  $^{52}_{24}\text{Cr}$  the most stable isotope of chromium?

**24.25** Why is  $^{40}_{20}\text{Ca}$  the most stable isotope of calcium?

#### Problems in Context

**24.26**  $^{237}\text{Np}$  is the parent nuclide of a decay series that starts with  $\alpha$  emission, followed by  $\beta^-$  emission, and then two more  $\alpha$  emissions. Write a balanced nuclear equation for each step.

**24.27** Why is helium found in deposits of uranium and thorium ores? What kind of radioactive emission produces it?

**24.28** In a natural decay series, how many  $\alpha$  and  $\beta^-$  emissions per atom of uranium-235 result in an atom of lead-207?

#### The Kinetics of Radioactive Decay

(Sample Problems 24.4 to 24.6)

#### Concept Review Questions

**24.29** What electronic process is the basis for detecting radioactivity in (a) a scintillation counter; (b) a Geiger-Müller counter?

**24.30** What is the reaction order of radioactive decay? Explain.

**24.31** After 1 min, three radioactive nuclei remain from an original sample of six. Is it valid to conclude that  $t_{1/2}$  equals 1 min? Is this conclusion valid if the original sample contained  $6 \times 10^{12}$  nuclei and  $3 \times 10^{12}$  remain after 1 min? Explain.

**24.32** Radioisotopic dating depends on the constant rate of decay and formation of various nuclides in a sample. How is the proportion of  $^{14}\text{C}$  kept relatively constant in living organisms?

### Skill-Building Exercises (grouped in similar pairs)

**24.33** What is the specific activity (in Ci/g) if 1.65 mg of an isotope emits  $1.56 \times 10^6$   $\alpha$  particles per second?

**24.34** What is the specific activity (in Ci/g) if 2.6 g of an isotope emits  $4.13 \times 10^8$   $\beta^-$  particles per hour?

**24.35** What is the specific activity (in Bq/g) if 8.58  $\mu\text{g}$  of an isotope emits  $7.4 \times 10^4$   $\alpha$  particles per minute?

**24.36** What is the specific activity (in Bq/g) if 1.07 kg of an isotope emits  $3.77 \times 10^7$   $\beta^-$  particles per minute?

**24.37** If one-trillionth of the atoms of a radioactive isotope disintegrate each day, what is the decay constant of the process?

**24.38** If  $2.8 \times 10^{-10}\%$  of the atoms of a radioactive isotope disintegrate in 1.0 yr, what is the decay constant of the process?

**24.39** If  $1.00 \times 10^{-12}$  mol of  $^{135}\text{Cs}$  emits  $1.39 \times 10^5$   $\beta^-$  particles in 1.00 yr, what is the decay constant?

**24.40** If  $6.40 \times 10^{-9}$  mol of  $^{176}\text{W}$  emits  $1.07 \times 10^{15}$   $\beta^+$  particles in 1.00 h, what is the decay constant?

**24.41** The isotope  $^{212}_{83}\text{Bi}$  has a half-life of 1.01 yr. What mass (in mg) of a 2.00-mg sample will remain after  $3.75 \times 10^3$  h?

**24.42** The half-life of radium-226 is  $1.60 \times 10^3$  yr. How many hours will it take for a 2.50-g sample to decay to the point where 0.185 g of the isotope remains?

**24.43** A rock contains 270  $\mu\text{mol}$  of  $^{238}\text{U}$  ( $t_{1/2} = 4.5 \times 10^9$  yr) and 110  $\mu\text{mol}$  of  $^{206}\text{Pb}$ . Assuming that all the  $^{206}\text{Pb}$  comes from decay of the  $^{238}\text{U}$ , estimate the rock's age.

**24.44** A fabric remnant from a burial site has a  $^{14}\text{C}/^{12}\text{C}$  ratio of 0.735 of the original value. How old is the fabric?

### Problems in Context

**24.45** Due to decay of  $^{40}\text{K}$ , cow's milk has a specific activity of about  $6 \times 10^{-11}$  mCi per milliliter. How many disintegrations of  $^{40}\text{K}$  nuclei are there per minute in an 8.0-oz glass of milk?

**24.46** Plutonium-239 ( $t_{1/2} = 2.41 \times 10^4$  yr) represents a serious nuclear waste hazard. If seven half-lives are required to reach a tolerable level of radioactivity, how long must  $^{239}\text{Pu}$  be stored?

**24.47** A rock that contains  $3.1 \times 10^{-15}$  mol of  $^{232}\text{Th}$  ( $t_{1/2} = 1.4 \times 10^{10}$  yr) has  $9.5 \times 10^4$  fission tracks, each track representing the fission of one atom of  $^{232}\text{Th}$ . How old is the rock?

**24.48** A volcanic eruption melts a large chunk of rock, and all gases are expelled. After cooling,  $^{40}\text{Ar}$  accumulates from the ongoing decay of  $^{40}\text{K}$  in the rock ( $t_{1/2} = 1.25 \times 10^9$  yr). When a piece of rock is analyzed, it is found to contain 1.38 mmol of  $^{40}\text{K}$  and 1.14 mmol of  $^{40}\text{Ar}$ . How long ago did the rock cool?

### Nuclear Transmutation: Induced Changes in Nuclei

#### Concept Review Questions

**24.49** Irene and Frederic Joliot-Curie converted  $^{27}_{13}\text{Al}$  to  $^{30}_{15}\text{P}$  in 1933. Why was this transmutation significant?

**24.50** Early workers mistakenly thought neutron beams were  $\gamma$  radiation. Why? What evidence led to the correct conclusion?

**24.51** Why must the electrical polarity of the tubes in a linear accelerator be reversed at very short time intervals?

**24.52** Why does bombardment with protons usually require higher energies than bombardment with neutrons?

### Skill-Building Exercises (grouped in similar pairs)

**24.53** Determine the missing species in these transmutations, and write a full nuclear equation from the shorthand notation:

(a)  $^{10}\text{B} (\alpha, n)$  \_\_\_\_\_

(b)  $^{28}\text{Si} (d, \_) ^{29}\text{P}$  (where d is a deuteron,  $^2\text{H}$ )

(c) \_\_\_\_\_  $(\alpha, 2n) ^{244}\text{Cf}$

**24.54** Name the unidentified species, and write each transmutation process in shorthand notation: (a) gamma irradiation of a nuclide yields a proton, a neutron, and  $^{29}\text{Si}$ ; (b) bombardment of  $^{252}\text{Cf}$  with  $^{10}\text{B}$  yields five neutrons and a nuclide; (c) bombardment of  $^{238}\text{U}$  with a particle yields three neutrons and  $^{239}\text{Pu}$ .

### Problems in Context

**24.55** Elements 104, 105, and 106 have been named rutherfordium (Rf), dubnium (Db), and seaborgium (Sg), respectively. These elements are synthesized from californium-249 by bombarding with carbon-12, nitrogen-15, and oxygen-18 nuclei, respectively. Four neutrons are formed in each reaction as well. (a) Write balanced nuclear equations for the formation of these elements. (b) Write the equations in shorthand notation.

### Ionization: Effects of Nuclear Radiation on Matter

#### Concept Review Questions

**24.56** The effects on matter of  $\gamma$  rays and  $\alpha$  particles differ. Explain.

**24.57** What is a cation-electron pair, and how does it form?

**24.58** Why is ionizing radiation more harmful to children than adults?

**24.59** Why is  $\cdot\text{OH}$  more dangerous than  $\text{OH}^-$  in an organism?

### Skill-Building Exercises (grouped in similar pairs)

**24.60** A 135-lb person absorbs  $3.3 \times 10^{-7}$  J of energy from radioactive emissions. (a) How many rads does she receive? (b) How many grays (Gy) does she receive?

**24.61** A 3.6-kg laboratory animal receives a single dose of  $8.92 \times 10^{-4}$  Gy. (a) How many rads did the animal receive? (b) How many joules did the animal absorb?

**24.62** A 70.-kg person exposed to  $^{90}\text{Sr}$  absorbs  $6.0 \times 10^5$   $\beta^-$  particles, each with an energy of  $8.74 \times 10^{-14}$  J. (a) How many grays does the person receive? (b) If the RBE is 1.0, how many millirems is this? (c) What is the equivalent dose in sieverts (Sv)?

**24.63** A laboratory rat weighs 265 g and absorbs  $1.77 \times 10^{10}$   $\beta^-$  particles, each with an energy of  $2.20 \times 10^{-13}$  J. (a) How many rads does the animal receive? (b) What is this dose in Gy? (c) If the RBE is 0.75, what is the equivalent dose in Sv?

### Problems in Context

**24.64** If 2.50 pCi [1 pCi (picocurie) =  $1 \times 10^{-12}$  Ci] of radioactivity from  $^{239}\text{Pu}$  is emitted in a 95-kg human for 65 h, and each disintegration has an energy of  $8.25 \times 10^{-13}$  J, how many grays does the person receive?

**24.65** A small region of a cancer patient's brain is exposed for 24.0 min to 475 Bq of radioactivity from  $^{60}\text{Co}$  for treatment of a tumor. If the brain mass exposed is 1.858 g and each  $\beta^-$  particle emitted has an energy of  $5.05 \times 10^{-14}$  J, what is the dose in rads?

### Applications of Radioisotopes

#### Concept Review Questions

**24.66** What two ways are radioactive tracers used in organisms?

**24.67** Why is neutron activation analysis (NAA) useful to art historians and criminologists?

**24.68** Positrons cannot penetrate matter more than a few atomic diameters, but positron emission of radiotracers can be monitored in medical diagnosis. Explain.

**24.69** A steel part is treated to form some iron-59. Oil used to lubricate the part emits 298  $\beta^-$  particles (with the energy characteristic of  $^{59}\text{Fe}$ ) per minute per milliliter of oil. What other information would you need to calculate the rate of removal of the steel from the part during use?

#### Problems in Context

**24.70** The oxidation of methanol to formaldehyde can be accomplished by reaction with chromic acid:

The reaction can be studied with the stable isotope tracer  $^{18}\text{O}$  and mass spectrometry. When a small amount of  $\text{CH}_3^{18}\text{OH}$  is present in the alcohol reactant,  $\text{CH}_2^{18}\text{O}$  forms. When a small amount of  $\text{H}_2\text{Cr}^{18}\text{O}_4$  is present,  $\text{H}_2^{18}\text{O}$  forms. Does chromic acid or methanol supply the O atom to the aldehyde? Explain.

### The Interconversion of Mass and Energy

(Sample Problem 24.7)

**Note:** Data for problems in this section: mass of  $^1\text{H}$  atom = 1.007825 amu; mass of neutron = 1.008665 amu.

#### Concept Review Questions

**24.71** Many scientists at first reacted skeptically to Einstein's equation,  $E = mc^2$ . Why?

**24.72** How does a change in mass arise when a nuclide forms from nucleons?

**24.73** When a nucleus forms from nucleons, is energy absorbed or released? Why?

**24.74** What is the binding energy per nucleon? Why is the binding energy per nucleon, rather than per nuclide, used to compare nuclide stability?

#### Skill-Building Exercises (grouped in similar pairs)

**24.75** A  $^3\text{H}$  nucleus decays with an energy of 0.01861 MeV. Convert this energy into (a) electron volts; (b) joules.

**24.76** Arsenic-84 decays with an energy of  $1.57 \times 10^{-15}$  kJ per nucleus. Convert this energy into (a) eV; (b) MeV.

**24.77** How many joules are released when 1.5 mol of  $^{239}\text{Pu}$  decays, if each nucleus releases 5.243 MeV?

**24.78** How many MeV are released per nucleus when  $3.2 \times 10^{-3}$  mol of chromium-49 releases  $8.11 \times 10^5$  kJ?

**24.79** Oxygen-16 is one of the most stable nuclides. The mass of a  $^{16}\text{O}$  atom is 15.994915 amu. Calculate the binding energy (a) per nucleon in MeV; (b) per atom in MeV; (c) per mole in kJ.

**24.80** Lead-206 is the end product of  $^{238}\text{U}$  decay. One  $^{206}\text{Pb}$  atom has a mass of 205.974440 amu. Calculate the binding energy (a) per nucleon in MeV; (b) per atom in MeV; (c) per mole in kJ.

**24.81** Cobalt-59 is the only stable isotope of this transition metal. One  $^{59}\text{Co}$  atom has a mass of 58.933198 amu. Calculate the binding energy (a) per nucleon in MeV; (b) per atom in MeV; (c) per mole in kJ.

**24.82** Iodine-131 is one of the most important isotopes used in the diagnosis of thyroid cancer. One atom has a mass of 130.906114 amu. Calculate the binding energy (a) per nucleon in MeV; (b) per atom in MeV; (c) per mole in kJ.

#### Problems in Context

**24.83** The  $^{80}\text{Br}$  nuclide decays either by  $\beta^-$  decay or by electron capture. (a) What is the product of each process? (b) Which process releases more energy? (Masses of atoms:  $^{80}\text{Br}$  = 79.918528 amu;  $^{80}\text{Kr}$  = 79.916380 amu;  $^{80}\text{Se}$  = 79.916520 amu; neglect the mass of electrons involved because these are atomic, not nuclear, masses.)

### Applications of Fission and Fusion

#### Concept Review Questions

**24.84** What is the minimum number of neutrons from each fission event that must be absorbed by other nuclei for a chain reaction to be sustained?

**24.85** In what main way is fission different from radioactive decay? Are all fission events in a chain reaction identical? Explain.

**24.86** What is the purpose of enrichment in the preparation of fuel rods? How is it accomplished?

**24.87** Describe the nature and purpose of these components of a nuclear reactor: (a) control rods; (b) moderator; (c) reflector.

**24.88** State an advantage and a disadvantage of heavy-water reactors compared to light-water reactors.

**24.89** What are the expected advantages of fusion reactors over fission reactors?

**24.90** Why is iron the most abundant element in Earth's core?

#### Problems in Context

**24.91** The reaction that will probably power the first commercial fusion reactor is

How much energy would be produced per mole of reaction? (Mass of  $^3_1\text{H}$  = 3.01605 amu; mass of  $^2_1\text{H}$  = 2.0140 amu; mass of  $^4_2\text{He}$  = 4.00260 amu; mass of  $^1_0\text{n}$  = 1.008665 amu.)

### Comprehensive Problems

**24.92** Some  $^{243}_{95}\text{Am}$  was present when Earth formed, but it all decayed in the next billion years. The first three steps in this decay series are emissions of an  $\alpha$  particle, a  $\beta^-$  particle, and another  $\alpha$  particle. What other isotopes were present on the young Earth in a rock that contained some  $^{243}_{95}\text{Am}$ ?

**24.93** Curium-243 undergoes  $\alpha$  decay to plutonium-239:

(a) Find the change in mass,  $\Delta m$  (in kg). (Mass of  $^{243}\text{Cm}$  = 243.0614 amu; mass of  $^{239}\text{Pu}$  = 239.0522 amu; mass of  $^4\text{He}$  = 4.0026 amu; 1 amu =  $1.661 \times 10^{-24}$  g.)

(b) Find the energy released in joules.

(c) Find the energy released in kJ/mol of reaction, and comment on the difference between this value and a typical heat of reaction for a chemical change, which is a few hundred kJ/mol.

**24.94** Plutonium “triggers” for nuclear weapons were manufactured at the Rocky Flats plant in Colorado. An 85-kg worker inhaled a dust particle containing 1.00  $\mu\text{g}$  of  $^{239}\text{Pu}$ , which resided in his body for 16 h ( $t_{1/2}$  of  $^{239}\text{Pu} = 2.41 \times 10^4$  yr; each disintegration released 5.15 MeV). (a) How many rads did he receive? (b) How many grays?

**24.95** Archeologists removed some charcoal from a Native American campfire site, burned it in  $\text{O}_2$ , and bubbled the  $\text{CO}_2$  formed into  $\text{Ca}(\text{OH})_2$  solution (limewater). The  $\text{CaCO}_3$  that precipitated was filtered and dried. If 4.58 g of the  $\text{CaCO}_3$  had a radioactivity of 3.2 d/min, how long ago was the campfire burning?

**24.96** A 5.4- $\mu\text{g}$  sample of  $^{226}\text{RaCl}_2$  has a radioactivity of  $1.5 \times 10^5$  Bq. Calculate  $t_{1/2}$  of  $^{226}\text{Ra}$ .

**24.97** How many rads does a 65-kg human receive each year from the approximately  $10^{-8}$  g of  $^{14}\text{C}$  naturally present in her body ( $t_{1/2} = 5730$  yr; each disintegration releases 0.156 MeV)?

**24.98** A sample of  $\text{AgCl}$  emits 175 nCi/g. A saturated solution prepared from the solid emits  $1.25 \times 10^{-2}$  Bq/mL due to radioactive  $\text{Ag}^+$  ions. What is the molar solubility of  $\text{AgCl}$ ?

**24.99** The scene below depicts a neutron bombarding  $^{235}\text{U}$ :

- (a) Is this an example of fission or of fusion?  
 (b) Identify the other nuclide formed.  
 (c) What is the most likely mode of decay of the nuclide with  $Z = 55$ ?

**24.100** What fraction of the  $^{235}\text{U}$  ( $t_{1/2} = 7.0 \times 10^8$  yr) created when Earth was formed would remain after  $2.8 \times 10^9$  yr?

**24.101**  $^{238}\text{U}$  ( $t_{1/2} = 4.5 \times 10^9$  yr) begins a decay series that ultimately forms  $^{206}\text{Pb}$ . The scene below depicts the relative number of  $^{238}\text{U}$  atoms (red) and  $^{206}\text{Pb}$  atoms (green) in a mineral. If all the Pb comes from  $^{238}\text{U}$ , calculate the age of the sample.

**24.102** Technetium-99m is a metastable nuclide used in numerous cancer diagnostic and treatment programs. It is prepared just before use because it decays rapidly through  $\gamma$  emission:

Use the data below to determine (a) the half-life of  $^{99\text{m}}\text{Tc}$ ; (b) the percentage of the isotope that is lost if it takes 2.0 h to prepare and administer the dose.

Time (h)	$\gamma$ Emission (photons/s)
0	5000.
4	3150.
8	2000.
12	1250.
16	788
20	495

**24.103** How many curies are produced by 1.0 mol of  $^{40}\text{K}$  ( $t_{1/2} = 1.25 \times 10^9$  yr)? How many becquerels?

**24.104** The fraction of a radioactive isotope remaining at time  $t$  is  $(\frac{1}{2})^{t/t_{1/2}}$ , where  $t_{1/2}$  is the half-life. If the half-life of carbon-14 is 5730 yr, what fraction of carbon-14 in a piece of charcoal remains after (a) 10.0 yr; (b)  $10.0 \times 10^3$  yr; (c)  $10.0 \times 10^4$  yr? (d) Why is radiocarbon dating more reliable for the fraction remaining in part (b) than that in part (a) or in part (c)?

**24.105** The isotopic mass of  $^{210}\text{Rn}$  is 209.989669 amu. When this nuclide decays by electron capture, it emits 2.368 MeV. What is the isotopic mass of the resulting nuclide?

**24.106** Exactly 0.1 of the radioactive nuclei in a sample decay per hour. Thus, after  $n$  hours, the fraction of nuclei remaining is  $(0.900)^n$ . Find the value of  $n$  equal to one half-life.

**24.107** In neutron activation analysis (NAA), stable isotopes are bombarded with neutrons. Depending on the isotope and the energy of the neutron, various emissions are observed. What are the products when the following neutron-activated species decay? Write an overall equation in shorthand notation for the reaction starting with the stable isotope before neutron activation.

**24.108** In the 1950s, radioactive material was spread over the land from aboveground nuclear tests. A woman drinks some contaminated milk and ingests 0.0500 g of  $^{90}\text{Sr}$ , which is taken up by bones and teeth and not eliminated. (a) How much  $^{90}\text{Sr}$  ( $t_{1/2} = 29$  yr) is present in her body after 10 yr? (b) How long will it take for 99.9% of the  $^{90}\text{Sr}$  that she ingested to decay?

**24.109** The scene below represents a reaction (with neutrons gray and protons purple) that occurs during the lifetime of a star. (a) Write a balanced nuclear equation for the reaction. (b) If the mass difference is  $7.7 \times 10^{-2}$  amu, find the energy (in kJ) released.

**24.110** What volume of radon will be produced per hour at STP from 1.000 g of  $^{226}\text{Ra}$  ( $t_{1/2} = 1599$  yr; 1 yr = 8766 h; mass of one  $^{226}\text{Ra}$  atom = 226.025402 amu)?

**24.111**  $^{90}\text{Kr}$  ( $t_{1/2} = 32$  s) is used to study respiration. How soon after being made must a sample be administered to the patient if the activity must be at least 90% of the original activity?

**24.112** Which isotope in each pair is more stable? Why?

**24.113** A bone sample containing strontium-90 ( $t_{1/2} = 29$  yr) emits  $7.0 \times 10^4$   $\beta^-$  particles per month. How long will it take for the emission to decrease to  $1.0 \times 10^4$  particles per month?

**24.114** The 23<sup>rd</sup>-century starship *Enterprise* uses a substance called “dilithium crystals” as its fuel.

- (a) Assuming that this material is the result of fusion, what is the product of the fusion of two  $^6\text{Li}$  nuclei?  
 (b) How much energy is released per kilogram of dilithium formed? (Mass of one  $^6\text{Li}$  atom is 6.015121 amu.)  
 (c) When four  $^1\text{H}$  atoms fuse to form  $^4\text{He}$ , how many positrons are released?

(d) To determine the energy potential of the fusion processes in parts (b) and (c), compare the changes in mass per kilogram of dilithium and of  ${}^4\text{He}$ .

(e) Compare the change in mass per kilogram in part (b) to that for the formation of  ${}^4\text{He}$  by the method used in current fusion reactors (see Section 24.7). (For masses, see Problem 24.91.)

(f) Using early 21<sup>st</sup>-century fusion technology, how much tritium can be produced per kilogram of  ${}^6\text{Li}$  in the following reaction:  ${}^6_3\text{Li} + {}^1_0\text{n} \rightarrow {}^4_2\text{He} + {}^3_1\text{H}$ ? When this amount of tritium is fused with deuterium, what is the change in mass? How does this quantity compare with the use of dilithium in part (b)?

**24.115** Uranium and radium are found in many rocky soils throughout the world. Both undergo radioactive decay, and one of the products is radon-222, the heaviest noble gas ( $t_{1/2} = 3.82$  days). Inhalation of this gas contributes to many lung cancers. According to the Environmental Protection Agency, the level of radioactivity from radon in homes should not exceed 4.0 pCi/L of air.

(a) What is the safe level of radon in Bq/L of air?

(b) A home has a radon measurement of 41.5 pCi/L. The owner vents the basement in such a way that no more radon enters the living area. What is the activity of the radon remaining in the room air (in Bq/L) after 9.5 days?

(c) How many more days does it take to reach the EPA recommended level?

**24.116** Nuclear disarmament could be accomplished if weapons were not “replenished.” The tritium in warheads decays to helium with a half-life of 12.26 yr and must be replaced or the weapon is useless. What fraction of the tritium is lost in 5.50 yr?

**24.117** A decay series starts with the synthetic isotope  ${}^{239}\text{U}$ . The first four steps are emissions of a  $\beta^-$  particle, another  $\beta^-$ , an  $\alpha$  particle, and another  $\alpha$ . Write a balanced nuclear equation for each step. Which natural series could start by this sequence?

**24.118** How long can a 54-lb child be exposed to 1.0 mCi of radiation from  ${}^{222}\text{Rn}$  before accumulating 1.0 mrad if the energy of each disintegration is 5.59 MeV?

**24.119** An earthquake in the area of present-day San Francisco is to be dated by measuring the  ${}^{14}\text{C}$  activity ( $t_{1/2} = 5730$  yr) of parts of a tree uprooted during the event. The tree parts have an activity of 12.9 d/min·g C, and a living tree has an activity of 15.3 d/min·g C. How long ago did the earthquake occur?

**24.120** Were organisms a billion years ago exposed to more or less ionizing radiation than similar organisms today? Explain.

**24.121** Tritium ( ${}^3\text{H}$ ;  $t_{1/2} = 12.26$  yr) is continually formed in the upper troposphere by interaction of solar particles with nitrogen. As a result, natural waters contain a small amount of tritium. Two samples of wine are analyzed, one known to be made in 1941 and another made earlier. The water in the 1941 wine has 2.23 times as much tritium as the water in the other. When was the other wine produced?

**24.122** Even though plutonium-239 ( $t_{1/2} = 2.41 \times 10^4$  yr) is one of the main fission fuels, it is still a radiation hazard present in spent uranium fuel from nuclear power plants. How many years does it take for 99% of the plutonium-239 in spent fuel to decay?

**24.123** Carbon from the remains of an extinct Australian marsupial, called *Diprotodon*, has a specific activity of 0.61 pCi/g. Modern carbon has a specific activity of 6.89 pCi/g. How long ago did the *Diprotodon* apparently become extinct?

**24.124** The reaction that allows radiocarbon dating to be performed is the continual formation of carbon-14 in the upper atmosphere:

What is the energy change that is associated with this process in eV/reaction and in kJ/mol reaction? (Masses of atoms:  ${}^{14}_7\text{N} = 14.003074$  amu;  ${}^{14}_6\text{C} = 14.003241$  amu;  ${}^1_1\text{H} = 1.007825$  amu; mass of  ${}^1_0\text{n} = 1.008665$  amu.)

**24.125** What is the nuclear binding energy of a lithium-7 nucleus in units of kJ/mol and eV/nucleus? (Mass of a lithium-7 atom = 7.016003 amu.)

**24.126** Gadolinium-146 undergoes electron capture. Identify the product, and use Figure 24.2 to find the modes of decay and the two intermediate nuclides in the series:

**24.127** Using 21<sup>st</sup>-century technology, hydrogen fusion requires temperatures around  $10^8$  K. But, lower initial temperatures are used if the hydrogen is compressed. In the late 24<sup>th</sup> century, the starship *Leinad* uses such methods to fuse hydrogen at  $10^6$  K.

(a) What is the kinetic energy of an H atom at  $1.00 \times 10^6$  K?

(b) How many H atoms are heated to  $1.00 \times 10^6$  K from the energy of one H and one anti-H atom annihilating each other?

(c) If the heated H atoms of part (b) fuse into  ${}^4\text{He}$  atoms (with the loss of two positrons per  ${}^4\text{He}$  formed), how much energy (in J) is generated?

(d) How much more energy is generated by the fusion in part (c) than by the hydrogen-antihydrogen collision in part (b)?

(e) Should the captain of the *Leinad* change the technology and produce  ${}^3\text{He}$  (mass = 3.01603 amu) instead of  ${}^4\text{He}$ ?

**24.128** A metastable (excited) form of  ${}^{50}\text{Sc}$  changes to its stable form by emitting  $\gamma$  radiation with a wavelength of 8.73 pm. What is the change in mass of 1 mol of the isotope when it undergoes this change?

**24.129** A sample of cobalt-60 ( $t_{1/2} = 5.27$  yr), a powerful  $\gamma$  emitter used to treat cancer, was purchased by a hospital on March 1, 2012. The sample must be replaced when its activity reaches 70% of the original value. On what date must it be replaced?

**24.130** Uranium-233 decays to thorium-229 by  $\alpha$  decay, but the emissions have different energies and products: 83% emit an  $\alpha$  particle with an energy of 4.816 MeV and give  ${}^{229}\text{Th}$  in its ground state; 15% emit an  $\alpha$  particle of 4.773 MeV and give  ${}^{229}\text{Th}$  in excited state I; and 2% emit a lower energy  $\alpha$  particle and give  ${}^{229}\text{Th}$  in the higher excited state II. Excited state II emits a  $\gamma$  ray of 0.060 MeV to reach excited state I.

(a) Find the  $\gamma$ -ray energy and wavelength that would convert excited state I to the ground state. (b) Find the energy of the  $\alpha$  particle that would raise  ${}^{233}\text{U}$  to excited state II.

**24.131** Uranium-238 undergoes a slow decay step ( $t_{1/2} = 4.5 \times 10^9$  yr) followed by a series of fast steps to form the stable isotope  ${}^{206}\text{Pb}$ . Thus, on a time scale of billions of years,  ${}^{238}\text{U}$  effectively decays “directly” to  ${}^{206}\text{Pb}$ , and the relative amounts of these isotopes are used to find the age of some rocks. Two students derive equations relating number of half-lives ( $n$ ) since the rock formed to the amounts of the isotopes:

Student 1: 
$$\left(\frac{1}{2}\right)^n = \frac{{}^{238}\text{U}}{{}^{206}\text{Pb}}$$

Student 2: 
$$\left(\frac{1}{2}\right)^n = \frac{{}^{238}_{92}\text{U}}{{}^{238}_{92}\text{U} + {}^{206}_{82}\text{Pb}}$$

(a) Which equation is correct, and why?

(b) If a rock contains exactly twice as much  ${}^{238}\text{U}$  as  ${}^{206}\text{Pb}$ , what is its age in years?

**24.132** In the naturally occurring thorium-232 decay series, the steps emit this sequence of particles:  $\alpha$ ,  $\beta^-$ ,  $\beta^-$ ,  $\alpha$ ,  $\alpha$ ,  $\alpha$ ,  $\beta^-$ ,  $\beta^-$ , and  $\alpha$ . Write a balanced equation for each step.

**24.133** At death, a nobleman in ancient Egypt was mummified and his body contained  $1.4 \times 10^{-3}$  g of  ${}^{40}\text{K}$  ( $t_{1/2} = 1.25 \times 10^9$  yr),  $1.2 \times 10^{-8}$  g of  ${}^{14}\text{C}$  ( $t_{1/2} = 5730$  yr), and  $4.8 \times 10^{-14}$  g of  ${}^3\text{H}$  ( $t_{1/2} = 12.26$  yr). Which nuclide would give the most accurate estimate of the mummy's age? Explain.

**24.134** Assuming that many radioactive nuclides can be considered safe after 20 half-lives, how long will it take for each of the following nuclides to be safe: (a)  ${}^{242}\text{Cm}$  ( $t_{1/2} = 163$  days); (b)  ${}^{214}\text{Po}$  ( $t_{1/2} = 1.6 \times 10^{-4}$  s); (c)  ${}^{232}\text{Th}$  ( $t_{1/2} = 1.39 \times 10^{10}$  yr)?

**24.135** An ancient sword has a blade from the early Roman Empire, around 100 AD, but the wooden handle, inlaid wooden decorations, leather ribbon, and leather sheath have different styles. Given the following activities, estimate the age of each part. Which part was made near the time of the blade ( $t_{1/2}$  of  ${}^{14}\text{C} = 5730$  yr;  $\mathcal{A}_0 = 15.3$  d/min·g)?

Part	$\mathcal{A}_t$ (d/min·g)
Handle	10.1
Inlaid wood	13.8
Ribbon	12.1
Sheath	15.0

**24.136** The starship *Voyager*, like many other vessels of the newly designed 24<sup>th</sup>-century fleet, uses antimatter as fuel.

(a) How much energy is released when 1.00 kg each of antimatter and matter annihilate each other?

(b) When the antimatter is atomic antihydrogen, a small amount of it is mixed with excess atomic hydrogen (gathered from interstellar space during flight). The annihilation releases so much heat that the remaining hydrogen nuclei fuse to form  ${}^4\text{He}$ . If each hydrogen-antihydrogen collision releases enough heat to fuse  $1.00 \times 10^5$  hydrogen atoms, how much energy (in kJ) is released per kilogram of antihydrogen?

(c) Which produces more energy per kilogram of antihydrogen, the procedure in part (a) or that in part (b)?

**24.137** Use Einstein's equation, the mass in grams of 1 amu, and the relation between electron volts and joules to find the energy equivalent (in MeV) of a mass difference of 1 amu.

**24.138** Determine the age of a rock containing 0.065 g of uranium-238 ( $t_{1/2} = 4.5 \times 10^9$  yr) and 0.023 g of lead-206. (Assume that all the lead-206 came from  ${}^{238}\text{U}$  decay.)

**24.139** Plutonium-242 decays to uranium-238 by emission of an  $\alpha$  particle with an energy of 4.853 MeV. The  ${}^{238}\text{U}$  that forms is unstable and emits a  $\gamma$  ray ( $\lambda = 0.02757$  nm). (a) Write balanced equations for these reactions. (b) What would be the energy of the  $\alpha$  particle if  ${}^{242}\text{Pu}$  decayed directly to the more stable  ${}^{238}\text{U}$ ?

**24.140** Seaborgium-263 (Sg), the first isotope of element 106 synthesized, was produced, along with four neutrons, by bombarding californium-249 with oxygen-18. The  ${}^{263}\text{Sg}$  then underwent a series of decays starting with three  $\alpha$  emissions. Write balanced equations for the synthesis and the three  $\alpha$  emissions of  ${}^{263}\text{Sg}$ .

**24.141** Some nuclear power plants use plutonium-239, which is produced in breeder reactors. The rate-determining step is the second  $\beta^-$  emission. How long does it take to make 1.00 kg of  ${}^{239}\text{Pu}$  if the reaction is complete when the product is 90.%  ${}^{239}\text{Pu}$ ?

**24.142** A random-number generator can be used to simulate the probability of a given atom decaying over a given time. For example, the formula “=RAND()” in an Excel spreadsheet returns a random number between 0 and 1; thus, for one radioactive atom and a time of one half-life, a number less than 0.5 means the atom decays and a number greater than 0.5 means it doesn't.

(a) Place the “=RAND()” formula in cells A1 to A10 of an Excel spreadsheet. In cell B1, place “=IF(A1<0.5, 0, 1).” This formula returns 0 if A1 is <0.5 (the atom decays) and 1 if A1 is >0.5 (the atom does not decay). Place analogous formulas in cells B2 to B10 (using the “Fill Down” procedure in Excel). To determine the number of atoms remaining after one half-life, sum cells B1 to B10 by placing “=SUM(B1:B10)” in cell B12. To create a new set of random numbers, click on an empty cell (e.g., B13) and hit “Delete.” Perform 10 simulations, each time recording the total number of atoms remaining. Do half of the atoms remain after each half-life? If not, why not? (b) Increase the number of atoms to 100 by placing suitable formulas in cells A1 to A100, B1 to B100, and B102. Perform 10 simulations, and record the number of atoms remaining each time. Are these results more realistic for radioactive decay? Explain.

**24.143** In the following Excel-based simulation, the fate of 256 atoms is followed over five half-lives. Set up formulas in columns A and B, as in Problem 24.142, and simulate the fate of the sample of 256 atoms over one half-life. Cells B1 to B256 should contain 1 or 0. In cell C1, enter “=IF(B1=0, 0, RAND()).” This returns 0 if the original atom decayed in the previous half-life or a random number between 0 and 1 if it did not. Fill the formula in C1 down to cell C256. Column D should have formulas similar to those in B, but with modified references, as should columns F, H, and J. Columns E, G, and I should have formulas similar to those in C, but with modified references. In cell B258, enter “=SUM(B1:B256).” This records the number of atoms remaining after the first half-life. Put formulas in cells D258, F258, H258, and J258 to record atoms remaining after subsequent half-lives.

(a) Ideally, how many atoms should remain after each half-life?

(b) Make a table of the atoms remaining after each half-life in four separate simulations. Compare these outcomes to the ideal outcome. How would you make the results more realistic?

**24.144** Representations of three nuclei (with neutrons *gray* and protons *purple*) are shown below. Nucleus 1 is stable, but 2 and 3 are not. (a) Write the symbol for each isotope. (b) What is (are) the most likely mode(s) of decay for 2 and 3?

# Common Mathematical Operations in Chemistry

In addition to basic arithmetic and algebra, four mathematical operations are used frequently in general chemistry: manipulating logarithms, using exponential notation, solving quadratic equations, and graphing data. Each is discussed briefly in this appendix.

## MANIPULATING LOGARITHMS

### Meaning and Properties of Logarithms

A *logarithm* is an exponent. Specifically, if  $x^n = A$ , we can say that the logarithm to the base  $x$  of the number  $A$  is  $n$ , and we can denote it as

$$\log_x A = n$$

Because logarithms are exponents, they have the following properties:

$$\begin{aligned}\log_x 1 &= 0 \\ \log_x (A \times B) &= \log_x A + \log_x B \\ \log_x \frac{A}{B} &= \log_x A - \log_x B \\ \log_x A^y &= y \log_x A\end{aligned}$$

### Types of Logarithms

Common and natural logarithms are used in chemistry and the other sciences.

1. For *common* logarithms, the base ( $x$  in the examples above) is 10, but they are written without specifying the base; that is,  $\log_{10} A$  is written more simply as  $\log A$ ; thus, the notation *log* means base 10. The common logarithm of 1000 is 3; in other words, you must raise 10 to the 3rd power to obtain 1000:

$$\log 1000 = 3 \quad \text{or} \quad 10^3 = 1000$$

Similarly, we have

$$\begin{array}{ll} \log 10 = 1 & \text{or} \quad 10^1 = 10 \\ \log 1,000,000 = 6 & \text{or} \quad 10^6 = 1,000,000 \\ \log 0.001 = -3 & \text{or} \quad 10^{-3} = 0.001 \\ \log 853 = 2.931 & \text{or} \quad 10^{2.931} = 853 \end{array}$$

The last example illustrates an important point about significant figures with all logarithms: *the number of significant figures in the number equals the number of digits to the right of the decimal point in the logarithm.* That is, the number 853 has three significant figures, and the logarithm 2.931 has three digits to the right of the decimal point.

To find a common logarithm with an electronic calculator, press the LOG button, enter the number, and press ENTER.

2. For *natural* logarithms, the base is the number  $e$ , which is 2.71828 . . . , and  $\log_e A$  is written  $\ln A$ ; thus, the notation *ln* means base  $e$ . The relationship between the common and natural logarithms is easily obtained:

$$\log 10 = 1 \quad \text{and} \quad \ln 10 = 2.303$$

Therefore, we have

$$\ln A = 2.303 \log A$$

To find a natural logarithm with an electronic calculator, press the LN button, enter the number, and press ENTER. If your calculator does not have an LN button, press the LOG button, enter the number, press ENTER, and multiply that result by 2.303.

## Antilogarithms

The *antilogarithm* is the base raised to the logarithm:

$$\text{antilogarithm (antilog) of } n \text{ is } 10^n$$

Using two of the earlier examples, the antilog of 3 is 1000, and the antilog of 2.931 is 853. To obtain the antilog with a calculator, press the  $10^x$  button, enter the number, and press ENTER. Similarly, to obtain the natural antilogarithm, press the  $e^x$  button, enter the number, and press ENTER. [On some calculators, enter the number and first press INV and then the LOG (or LN) button.]

## USING EXPONENTIAL (SCIENTIFIC) NOTATION

Many quantities in chemistry are very large or very small. For example, in the conventional way of writing numbers, the number of gold atoms in 1 gram of gold is

$$59,060,000,000,000,000,000 \text{ atoms (to four significant figures)}$$

As another example, the mass in grams of one gold atom is

$$0.0000000000000000000000003272 \text{ g (to four significant figures)}$$

Exponential (scientific) notation provides a much more practical way of writing such numbers. In exponential notation, we express numbers in the form

$$A \times 10^n$$

where  $A$  (the coefficient) is greater than or equal to 1 and less than 10 (that is,  $1 \leq A < 10$ ), and  $n$  (the exponent) is an integer.

If the number we want to express in exponential notation is larger than 1, the exponent is positive ( $n > 0$ ); if the number is smaller than 1, the exponent is negative ( $n < 0$ ). The size of  $n$  tells the number of places the decimal point (in conventional notation) must be moved to obtain a coefficient  $A$  greater than or equal to 1 and less than 10 (in exponential notation). In exponential notation, 1 gram of gold contains  $5.906 \times 10^{22}$  atoms, and each gold atom has a mass of  $3.272 \times 10^{-22}$  g.

## Changing Between Conventional and Exponential Notation

In order to use exponential notation, you must be able to convert to it from conventional notation, and vice versa.

1. To change a number from conventional to exponential notation, move the decimal point to the left for numbers equal to or greater than 10 and to the right for numbers between 0 and 1:

$$75,000,000 \text{ changes to } 7.5 \times 10^7 \text{ (decimal point moves 7 places to the left)}$$

$$0.006042 \text{ changes to } 6.042 \times 10^{-3} \text{ (decimal point moves 3 places to the right)}$$

2. To change a number from exponential to conventional notation, move the decimal point the number of places indicated by the exponent to the right for numbers with positive exponents and to the left for numbers with negative exponents:

$$1.38 \times 10^5 \text{ changes to } 138,000 \text{ (decimal point moves 5 places to the right)}$$

$$8.41 \times 10^{-6} \text{ changes to } 0.00000841 \text{ (decimal point moves 6 places to the left)}$$

3. An exponential number with a coefficient greater than 10 or less than 1 can be changed to the standard exponential form by converting the coefficient to the standard form and adding the exponents:

$$582.3 \times 10^6 \text{ changes to } 5.823 \times 10^2 \times 10^6 = 5.823 \times 10^{(2+6)} = 5.823 \times 10^8$$

$$0.0043 \times 10^{-4} \text{ changes to } 4.3 \times 10^{-3} \times 10^{-4} = 4.3 \times 10^{[(-3)+(-4)]} = 4.3 \times 10^{-7}$$

## Using Exponential Notation in Calculations

In calculations, you can treat the coefficient and exponents separately and apply the properties of exponents (see earlier discussion of logarithms).

1. To multiply exponential numbers, multiply the coefficients, add the exponents, and reconstruct the number in standard exponential notation:

$$(5.5 \times 10^3)(3.1 \times 10^5) = (5.5 \times 3.1) \times 10^{(3+5)} = 17 \times 10^8 = 1.7 \times 10^9$$

$$(9.7 \times 10^{14})(4.3 \times 10^{-20}) = (9.7 \times 4.3) \times 10^{[14+(-20)]} = 42 \times 10^{-6} = 4.2 \times 10^{-5}$$

2. To divide exponential numbers, divide the coefficients, subtract the exponents, and reconstruct the number in standard exponential notation:

$$\frac{2.6 \times 10^6}{5.8 \times 10^2} = \frac{2.6}{5.8} \times 10^{(6-2)} = 0.45 \times 10^4 = 4.5 \times 10^3$$

$$\frac{1.7 \times 10^{-5}}{8.2 \times 10^{-8}} = \frac{1.7}{8.2} \times 10^{[(-5)-(-8)]} = 0.21 \times 10^3 = 2.1 \times 10^2$$

3. To add or subtract exponential numbers, change all numbers so that they have the same exponent, then add or subtract the coefficients:

$$(1.45 \times 10^4) + (3.2 \times 10^3) = (1.45 \times 10^4) + (0.32 \times 10^4) = 1.77 \times 10^4$$

$$(3.22 \times 10^5) - (9.02 \times 10^4) = (3.22 \times 10^5) - (0.902 \times 10^5) = 2.32 \times 10^5$$

## SOLVING QUADRATIC EQUATIONS

A *quadratic equation* is one in which the highest power of  $x$  is 2. The general form of a quadratic equation is

$$ax^2 + bx + c = 0$$

where  $a$ ,  $b$ , and  $c$  are numbers. For given values of  $a$ ,  $b$ , and  $c$ , the values of  $x$  that satisfy the equation are called *solutions* of the equation. We calculate  $x$  with the quadratic formula:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

We commonly require the quadratic formula when solving for some concentration in an equilibrium problem. For example, we might have an expression that is rearranged into the quadratic equation

$$4.3x^2 + 0.65x - 8.7 = 0$$

Applying the quadratic formula, with  $a = 4.3$ ,  $b = 0.65$ , and  $c = -8.7$ , gives

$$x = \frac{-0.65 \pm \sqrt{(0.65)^2 - 4(4.3)(-8.7)}}{2(4.3)}$$

The “plus or minus” sign ( $\pm$ ) indicates that there are always two possible values for  $x$ . In this case, they are

$$x = 1.3 \quad \text{and} \quad x = -1.5$$

In any real physical system, however, only one of the values will have any meaning. For example, if  $x$  were  $[\text{H}_3\text{O}^+]$ , the negative value would give a negative concentration, which has no physical meaning.

## GRAPHING DATA IN THE FORM OF A STRAIGHT LINE

Visualizing changes in variables by means of a graph is used throughout science. In many cases, it is most useful if the data can be graphed in the form of a straight line. Any equation will appear as a straight line if it has, or can be rearranged to have, the following general form:

$$y = mx + b$$

where  $y$  is the dependent variable (typically plotted along the vertical axis),  $x$  is the independent variable (typically plotted along the horizontal axis),  $m$  is the slope of the line, and  $b$  is the intercept of the line on the  $y$  axis. The intercept is the value of  $y$  when  $x = 0$ :

$$y = m(0) + b = b$$

The slope of the line is the change in  $y$  for a given change in  $x$ :

$$\text{Slope } (m) = \frac{y_2 - y_1}{x_2 - x_1} = \frac{\Delta y}{\Delta x}$$

The *sign* of the slope tells the *direction* in which the line slants. If  $y$  increases as  $x$  increases,  $m$  is positive, and the line slopes upward with higher values of  $x$ ; if  $y$  decreases as  $x$  increases,  $m$  is negative, and the line slopes downward with higher values of  $x$ . The *magnitude* of the slope indicates the *steepness* of the line. A line with  $m = 3$  is three times as steep ( $y$  changes three times as much for a given change in  $x$ ) as a line with  $m = 1$ .

Consider the linear equation  $y = 2x + 1$ . A graph of this equation is shown in Figure A.1. In practice, you can find the slope by drawing a right triangle for which the line is the hypotenuse. Then, one leg gives  $\Delta y$ , and the other gives  $\Delta x$ . In the figure,  $\Delta y = 8$  and  $\Delta x = 4$ .

At several places in the text, an equation is rearranged into the form of a straight line in order to determine information from the slope and/or the intercept. For example, in Chapter 16, we obtained the following expression:

$$\ln \frac{[A]_0}{[A]_t} = kt$$

Based on the properties of logarithms, we have

$$\ln [A]_0 - \ln [A]_t = kt$$

Rearranging into the form of an equation for a straight line gives

$$\begin{aligned} \ln [A]_t &= -kt + \ln [A]_0 \\ y &= mx + b \end{aligned}$$

Thus, a plot of  $\ln [A]_t$  vs.  $t$  is a straight line, from which you can see that the slope is  $-k$  (the negative of the rate constant) and the intercept is  $\ln [A]_0$  (the natural logarithm of the initial concentration of A).

At many other places in the text, linear relationships occur that were not shown in graphical terms. For example, the conversion of temperature scales in Chapter 1 can also be expressed in the form of a straight line:

$$\begin{aligned} T(\text{in } ^\circ\text{F}) &= \frac{9}{5}T(\text{in } ^\circ\text{C}) + 32 \\ y &= mx + b \end{aligned}$$

Figure A.1

# APPENDIX C

## Equilibrium Constants for Selected Substances\*

### Dissociation (Ionization) Constants ( $K_a$ ) of Selected Acids

Name and Formula	Lewis Structure <sup>†</sup>	$K_{a1}$	$K_{a2}$	$K_{a3}$
Acetic acid CH <sub>3</sub> COOH		$1.8 \times 10^{-5}$		
Acetylsalicylic acid CH <sub>3</sub> COOC <sub>6</sub> H <sub>4</sub> COOH		$3.6 \times 10^{-4}$		
Adipic acid HOOC(CH <sub>2</sub> ) <sub>4</sub> COOH		$3.8 \times 10^{-5}$	$3.8 \times 10^{-6}$	
Arsenic acid H <sub>3</sub> AsO <sub>4</sub>		$6 \times 10^{-3}$	$1.1 \times 10^{-7}$	$3 \times 10^{-12}$
Ascorbic acid H <sub>2</sub> C <sub>6</sub> H <sub>6</sub> O <sub>6</sub>		$1.0 \times 10^{-5}$	$5 \times 10^{-12}$	
Benzoic acid C <sub>6</sub> H <sub>5</sub> COOH		$6.3 \times 10^{-5}$		
Carbonic acid H <sub>2</sub> CO <sub>3</sub>		$4.5 \times 10^{-7}$	$4.7 \times 10^{-11}$	
Chloroacetic acid ClCH <sub>2</sub> COOH		$1.4 \times 10^{-3}$		
Chlorous acid HClO <sub>2</sub>		$1.1 \times 10^{-2}$		

\*All values at 298 K, except for acetylsalicylic acid, which is at 37°C (310 K) in 0.15 M NaCl.

<sup>†</sup>Acidic (ionizable) proton(s) shown in red. Structures have lowest formal charges. Benzene rings show one resonance form.

Dissociation (Ionization) Constants ( $K_b$ ) of Selected Amine Bases

Name and Formula	Lewis Structure <sup>†</sup>	$K_{b1}$	$K_{b2}$
Ammonia NH <sub>3</sub>		$1.76 \times 10^{-5}$	
Aniline C <sub>6</sub> H <sub>5</sub> NH <sub>2</sub>		$4.0 \times 10^{-10}$	
Diethylamine (CH <sub>3</sub> CH <sub>2</sub> ) <sub>2</sub> NH		$8.6 \times 10^{-4}$	
Dimethylamine (CH <sub>3</sub> ) <sub>2</sub> NH		$5.9 \times 10^{-4}$	
Ethanolamine HOCH <sub>2</sub> CH <sub>2</sub> NH <sub>2</sub>		$3.2 \times 10^{-5}$	
Ethylamine CH <sub>3</sub> CH <sub>2</sub> NH <sub>2</sub>		$4.3 \times 10^{-4}$	
Ethylenediamine H <sub>2</sub> NCH <sub>2</sub> CH <sub>2</sub> NH <sub>2</sub>		$8.5 \times 10^{-5}$	$7.1 \times 10^{-8}$
Methylamine CH <sub>3</sub> NH <sub>2</sub>		$4.4 \times 10^{-4}$	
<i>tert</i> -Butylamine (CH <sub>3</sub> ) <sub>3</sub> CNH <sub>2</sub>		$4.8 \times 10^{-4}$	
Piperidine C <sub>5</sub> H <sub>10</sub> NH		$1.3 \times 10^{-3}$	
<i>n</i> -Propylamine CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> NH <sub>2</sub>		$3.5 \times 10^{-4}$	

<sup>†</sup>Blue type indicates the basic nitrogen and its lone pair.

**Dissociation (Ionization) Constants ( $K_b$ ) of Selected Amine Bases (continued)**

Name and Formula	Lewis Structure <sup>†</sup>	$K_{b1}$	$K_{b2}$
Isopropylamine (CH <sub>3</sub> ) <sub>2</sub> CHNH <sub>2</sub>		$4.7 \times 10^{-4}$	
1,3-Propylenediamine H <sub>2</sub> NCH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> NH <sub>2</sub>		$3.1 \times 10^{-4}$	$3.0 \times 10^{-6}$
Pyridine C <sub>5</sub> H <sub>5</sub> N		$1.7 \times 10^{-9}$	
Triethylamine (CH <sub>3</sub> CH <sub>2</sub> ) <sub>3</sub> N		$5.2 \times 10^{-4}$	
Trimethylamine (CH <sub>3</sub> ) <sub>3</sub> N		$6.3 \times 10^{-5}$	

**Dissociation (Ionization) Constants ( $K_a$ ) of Some Hydrated Metal Ions**

Free Ion	Hydrated Ion	$K_a$
Fe <sup>3+</sup>	Fe(H <sub>2</sub> O) <sub>6</sub> <sup>3+</sup> (aq)	$6 \times 10^{-3}$
Sn <sup>2+</sup>	Sn(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup> (aq)	$4 \times 10^{-4}$
Cr <sup>3+</sup>	Cr(H <sub>2</sub> O) <sub>6</sub> <sup>3+</sup> (aq)	$1 \times 10^{-4}$
Al <sup>3+</sup>	Al(H <sub>2</sub> O) <sub>6</sub> <sup>3+</sup> (aq)	$1 \times 10^{-5}$
Cu <sup>2+</sup>	Cu(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup> (aq)	$3 \times 10^{-8}$
Pb <sup>2+</sup>	Pb(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup> (aq)	$3 \times 10^{-8}$
Zn <sup>2+</sup>	Zn(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup> (aq)	$1 \times 10^{-9}$
Co <sup>2+</sup>	Co(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup> (aq)	$2 \times 10^{-10}$
Ni <sup>2+</sup>	Ni(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup> (aq)	$1 \times 10^{-10}$

**Formation Constants ( $K_f$ ) of Some Complex Ions**

Complex Ion	$K_f$
Ag(CN) <sub>2</sub> <sup>-</sup>	$3.0 \times 10^{20}$
Ag(NH <sub>3</sub> ) <sub>2</sub> <sup>+</sup>	$1.7 \times 10^7$
Ag(S <sub>2</sub> O <sub>3</sub> ) <sub>2</sub> <sup>3-</sup>	$4.7 \times 10^{13}$
AlF <sub>6</sub> <sup>3-</sup>	$4 \times 10^{19}$
Al(OH) <sub>4</sub> <sup>-</sup>	$3 \times 10^{33}$
Be(OH) <sub>4</sub> <sup>2-</sup>	$4 \times 10^{18}$
CdI <sub>4</sub> <sup>2-</sup>	$1 \times 10^6$
Co(OH) <sub>4</sub> <sup>2-</sup>	$5 \times 10^9$
Cr(OH) <sub>4</sub> <sup>-</sup>	$8.0 \times 10^{29}$
Cu(NH <sub>3</sub> ) <sub>4</sub> <sup>2+</sup>	$5.6 \times 10^{11}$
Fe(CN) <sub>6</sub> <sup>4-</sup>	$3 \times 10^{35}$
Fe(CN) <sub>6</sub> <sup>3-</sup>	$4.0 \times 10^{43}$
Hg(CN) <sub>4</sub> <sup>2-</sup>	$9.3 \times 10^{38}$
Ni(NH <sub>3</sub> ) <sub>6</sub> <sup>2+</sup>	$2.0 \times 10^8$
Pb(OH) <sub>3</sub> <sup>-</sup>	$8 \times 10^{13}$
Sn(OH) <sub>3</sub> <sup>-</sup>	$3 \times 10^{25}$
Zn(CN) <sub>4</sub> <sup>2-</sup>	$4.2 \times 10^{19}$
Zn(NH <sub>3</sub> ) <sub>4</sub> <sup>2+</sup>	$7.8 \times 10^8$
Zn(OH) <sub>4</sub> <sup>2-</sup>	$3 \times 10^{15}$

Solubility-Product Constants ( $K_{sp}$ ) of Slightly Soluble Ionic Compounds

Name, Formula	$K_{sp}$	Name, Formula	$K_{sp}$
<b>Carbonates</b>		Cobalt(II) hydroxide, $\text{Co}(\text{OH})_2$	$1.3 \times 10^{-15}$
Barium carbonate, $\text{BaCO}_3$	$2.0 \times 10^{-9}$	Copper(II) hydroxide, $\text{Cu}(\text{OH})_2$	$2.2 \times 10^{-20}$
Cadmium carbonate, $\text{CdCO}_3$	$1.8 \times 10^{-14}$	Iron(II) hydroxide, $\text{Fe}(\text{OH})_2$	$4.1 \times 10^{-15}$
Calcium carbonate, $\text{CaCO}_3$	$3.3 \times 10^{-9}$	Iron(III) hydroxide, $\text{Fe}(\text{OH})_3$	$1.6 \times 10^{-39}$
Cobalt(II) carbonate, $\text{CoCO}_3$	$1.0 \times 10^{-10}$	Magnesium hydroxide, $\text{Mg}(\text{OH})_2$	$6.3 \times 10^{-10}$
Copper(II) carbonate, $\text{CuCO}_3$	$3 \times 10^{-12}$	Manganese(II) hydroxide, $\text{Mn}(\text{OH})_2$	$1.6 \times 10^{-13}$
Lead(II) carbonate, $\text{PbCO}_3$	$7.4 \times 10^{-14}$	Nickel(II) hydroxide, $\text{Ni}(\text{OH})_2$	$6 \times 10^{-16}$
Magnesium carbonate, $\text{MgCO}_3$	$3.5 \times 10^{-8}$	Zinc hydroxide, $\text{Zn}(\text{OH})_2$	$3 \times 10^{-16}$
Mercury(I) carbonate, $\text{Hg}_2\text{CO}_3$	$8.9 \times 10^{-17}$	<b>Iodates</b>	
Nickel(II) carbonate, $\text{NiCO}_3$	$1.3 \times 10^{-7}$	Barium iodate, $\text{Ba}(\text{IO}_3)_2$	$1.5 \times 10^{-9}$
Strontium carbonate, $\text{SrCO}_3$	$5.4 \times 10^{-10}$	Calcium iodate, $\text{Ca}(\text{IO}_3)_2$	$7.1 \times 10^{-7}$
Zinc carbonate, $\text{ZnCO}_3$	$1.0 \times 10^{-10}$	Lead(II) iodate, $\text{Pb}(\text{IO}_3)_2$	$2.5 \times 10^{-13}$
<b>Chromates</b>		Silver iodate, $\text{AgIO}_3$	$3.1 \times 10^{-8}$
Barium chromate, $\text{BaCrO}_4$	$2.1 \times 10^{-10}$	Strontium iodate, $\text{Sr}(\text{IO}_3)_2$	$3.3 \times 10^{-7}$
Calcium chromate, $\text{CaCrO}_4$	$1 \times 10^{-8}$	Zinc iodate, $\text{Zn}(\text{IO}_3)_2$	$3.9 \times 10^{-6}$
Lead(II) chromate, $\text{PbCrO}_4$	$2.3 \times 10^{-13}$	<b>Oxalates</b>	
Silver chromate, $\text{Ag}_2\text{CrO}_4$	$2.6 \times 10^{-12}$	Barium oxalate dihydrate, $\text{BaC}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$	$1.1 \times 10^{-7}$
<b>Cyanides</b>		Calcium oxalate monohydrate, $\text{CaC}_2\text{O}_4 \cdot \text{H}_2\text{O}$	$2.3 \times 10^{-9}$
Mercury(I) cyanide, $\text{Hg}_2(\text{CN})_2$	$5 \times 10^{-40}$	Strontium oxalate monohydrate, $\text{SrC}_2\text{O}_4 \cdot \text{H}_2\text{O}$	$5.6 \times 10^{-8}$
Silver cyanide, $\text{AgCN}$	$2.2 \times 10^{-16}$	<b>Phosphates</b>	
<b>Halides</b>		Calcium phosphate, $\text{Ca}_3(\text{PO}_4)_2$	$1.2 \times 10^{-29}$
<i>Fluorides</i>		Magnesium phosphate, $\text{Mg}_3(\text{PO}_4)_2$	$5.2 \times 10^{-24}$
Barium fluoride, $\text{BaF}_2$	$1.5 \times 10^{-6}$	Silver phosphate, $\text{Ag}_3\text{PO}_4$	$2.6 \times 10^{-18}$
Calcium fluoride, $\text{CaF}_2$	$3.2 \times 10^{-11}$	<b>Sulfates</b>	
Lead(II) fluoride, $\text{PbF}_2$	$3.6 \times 10^{-8}$	Barium sulfate, $\text{BaSO}_4$	$1.1 \times 10^{-10}$
Magnesium fluoride, $\text{MgF}_2$	$7.4 \times 10^{-9}$	Calcium sulfate, $\text{CaSO}_4$	$2.4 \times 10^{-5}$
Strontium fluoride, $\text{SrF}_2$	$2.6 \times 10^{-9}$	Lead(II) sulfate, $\text{PbSO}_4$	$1.6 \times 10^{-8}$
<i>Chlorides</i>		Radium sulfate, $\text{RaSO}_4$	$2 \times 10^{-11}$
Copper(I) chloride, $\text{CuCl}$	$1.9 \times 10^{-7}$	Silver sulfate, $\text{Ag}_2\text{SO}_4$	$1.5 \times 10^{-5}$
Lead(II) chloride, $\text{PbCl}_2$	$1.7 \times 10^{-5}$	Strontium sulfate, $\text{SrSO}_4$	$3.2 \times 10^{-7}$
Silver chloride, $\text{AgCl}$	$1.8 \times 10^{-10}$	<b>Sulfides</b>	
<i>Bromides</i>		Cadmium sulfide, $\text{CdS}$	$1.0 \times 10^{-24}$
Copper(I) bromide, $\text{CuBr}$	$5 \times 10^{-9}$	Copper(II) sulfide, $\text{CuS}$	$8 \times 10^{-34}$
Silver bromide, $\text{AgBr}$	$5.0 \times 10^{-13}$	Iron(II) sulfide, $\text{FeS}$	$8 \times 10^{-16}$
<i>Iodides</i>		Lead(II) sulfide, $\text{PbS}$	$3 \times 10^{-25}$
Copper(I) iodide, $\text{CuI}$	$1 \times 10^{-12}$	Manganese(II) sulfide, $\text{MnS}$	$3 \times 10^{-11}$
Lead(II) iodide, $\text{PbI}_2$	$7.9 \times 10^{-9}$	Mercury(II) sulfide, $\text{HgS}$	$2 \times 10^{-50}$
Mercury(I) iodide, $\text{Hg}_2\text{I}_2$	$4.7 \times 10^{-29}$	Nickel(II) sulfide, $\text{NiS}$	$3 \times 10^{-16}$
Silver iodide, $\text{AgI}$	$8.3 \times 10^{-17}$	Silver sulfide, $\text{Ag}_2\text{S}$	$8 \times 10^{-48}$
<b>Hydroxides</b>		Tin(II) sulfide, $\text{SnS}$	$1.3 \times 10^{-23}$
Aluminum hydroxide, $\text{Al}(\text{OH})_3$	$3 \times 10^{-34}$	Zinc sulfide, $\text{ZnS}$	$2.0 \times 10^{-22}$
Cadmium hydroxide, $\text{Cd}(\text{OH})_2$	$7.2 \times 10^{-15}$		
Calcium hydroxide, $\text{Ca}(\text{OH})_2$	$6.5 \times 10^{-6}$		

## Standard Electrode (Half-Cell) Potentials\*

Half-Reaction	$E^\circ$ (V)
$F_2(g) + 2e^- \rightleftharpoons 2F^-(aq)$	+2.87
$O_3(g) + 2H^+(aq) + 2e^- \rightleftharpoons O_2(g) + H_2O(l)$	+2.07
$Co^{3+}(aq) + e^- \rightleftharpoons Co^{2+}(aq)$	+1.82
$H_2O_2(aq) + 2H^+(aq) + 2e^- \rightleftharpoons 2H_2O(l)$	+1.77
$PbO_2(s) + 3H^+(aq) + HSO_4^-(aq) + 2e^- \rightleftharpoons PbSO_4(s) + 2H_2O(l)$	+1.70
$Ce^{4+}(aq) + e^- \rightleftharpoons Ce^{3+}(aq)$	+1.61

$Ba^{2+}(aq) + 2e^- \rightleftharpoons Ba(s)$	-2.90
$K^+(aq) + e^- \rightleftharpoons K(s)$	-2.93
$Li^+(aq) + e^- \rightleftharpoons Li(s)$	-3.05

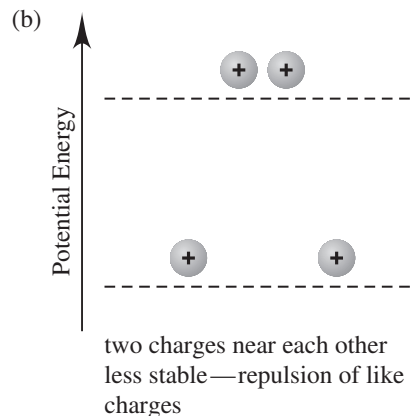

\*All values at 298 K. Written as reductions;  $E^\circ$  value refers to all components in their standard states: 1 M for dissolved species; 1 atm pressure for the gas behaving ideally; the pure substance for solids and liquids.

# Answers to Selected Problems

## Chapter 1

**1.2** Gas molecules fill the entire container; the volume of a gas is the volume of the container. Solids and liquids have a definite volume. The volume of the container does not affect the volume of a solid or liquid. (a) gas (b) liquid (c) liquid **1.4** Physical property: a characteristic shown by a substance itself, without any interaction with or change into other substances. Chemical property: a characteristic of a substance that appears as it interacts with, or transforms into, other substances. (a) Color (yellow-green and silver to white) and physical state (gas and metal to crystals) are physical properties. The interaction between chlorine gas and sodium metal is a chemical change. (b) Color and magnetism are physical properties. No chemical changes. **1.6**(a) Physical change; there is only a temperature change. (b) Chemical change; the change in appearance indicates an irreversible chemical change. (c) Physical change; there is only a change in size, not composition. (d) Chemical change; the wood (and air) become different substances with different compositions. **1.8**(a) fuel (b) wood **1.13** Lavoisier measured the total mass of the reactants and products, not just the mass of the solids, and this total mass remained constant. His measurements showed that a gas was involved in the reaction. He called this gas *oxygen* (one of his key discoveries). **1.16** A well-designed experiment must have the following: (1) at least two variables that are related; (2) a way to control all the variables, so that only one at a time may be changed; (3) reproducible results. **1.20**(a) increases (b) remains the same (c) decreases (d) increases (e) remains the same **1.23** An extensive property depends on the amount of material present. An intensive property is the same regardless of how much material is present. (a) extensive property (b) intensive property (c) extensive property (d) intensive property **1.24**(a)  $(2.54 \text{ cm})^2/(1 \text{ in})^2$  and  $(1 \text{ m})^2/(100 \text{ cm})^2$  (b)  $(1000 \text{ m})^2/(1 \text{ km})^2$  and  $(100 \text{ cm})^2/(1 \text{ m})^2$  (c)  $(1.609 \times 10^3 \text{ m/mi})$  and  $(1 \text{ h}/3600 \text{ s})$  (d)  $(1000 \text{ g}/2.205 \text{ lb})$  and  $(3.531 \times 10^{-5} \text{ ft}^3/\text{cm}^3)$  **1.26** 1.43 nm **1.28**  $3.94 \times 10^3 \text{ in}$  **1.30** (a)  $2.07 \times 10^{-9} \text{ km}^2$  (b) \$10.43 **1.32** Answers will vary, depending on the person's mass. **1.34**(a)  $5.52 \times 10^3 \text{ kg/m}^3$  (b) 345 lb/ft<sup>3</sup> **1.36**(a)  $2.56 \times 10^{-9} \text{ mm}^3$  (b)  $10^{-10} \text{ L}$  **1.38**(a) 9.626 cm<sup>3</sup> (b) 64.92 g **1.40** 2.70 g/cm<sup>3</sup> **1.42**(a) 20.°C; 293 K (b) 109 K; -263°F (c) -273°C; -460.°F **1.45**(a)  $2.47 \times 10^{-7} \text{ m}$  (b) 67.6 Å **1.52**(a) none (b) none (c) 0.0410 (d)  $4.0100 \times 10^4$  **1.54**(a) 0.00036 (b) 35.83 (c) 22.5 **1.56**  $6 \times 10^2$  **1.58**(a) 1.34 m (b) 21,621 mm<sup>3</sup> (c) 443 cm **1.60**(a)  $1.310000 \times 10^5$  (b)  $4.7 \times 10^{-4}$  (c)  $2.10006 \times 10^5$  (d)  $2.1605 \times 10^3$  **1.62**(a) 5550 (b) 10,070. (c) 0.000000885 (d) 0.003004 **1.64**(a)  $8.025 \times 10^4$  (b)  $1.0098 \times 10^{-3}$  (c)  $7.7 \times 10^{-11}$  **1.66**(a)  $4.06 \times 10^{-19} \text{ J}$  (b)  $1.61 \times 10^{24}$  molecules (c)  $1.82 \times 10^5 \text{ J/mol}$  **1.68**(a) Height measured, not exact. (b) Planets counted, exact. (c) Number of grams in a pound is not a unit definition, not exact. (d) Definition of a millimeter, exact. **1.70**  $7.50 \pm 0.05 \text{ cm}$

**1.72**(a)  $I_{\text{avg}} = 8.72 \text{ g}$ ;  $II_{\text{avg}} = 8.72 \text{ g}$ ;  $III_{\text{avg}} = 8.50 \text{ g}$ ;  $IV_{\text{avg}} = 8.56 \text{ g}$ ; sets I and II are most accurate. (b) Set III is the most precise but is the least accurate. (c) Set I has the best combination of high accuracy and high precision. (d) Set IV has both low accuracy and low precision.

**1.76** 7.7/1 **1.78**(a) density = 0.21 g/L, will float (b) CO<sub>2</sub> is denser than air, will sink (c) density = 0.30 g/L, will float (d) O<sub>2</sub> is denser than air, will sink (e) density = 1.38 g/L, will sink (f) 0.55 g for empty ball; 0.50 g for ball filled with hydrogen **1.80**(a)  $8.0 \times 10^{12} \text{ g}$  (b)  $4.1 \times 10^5 \text{ m}^3$  (c)  $4.1 \times 10^{14}$  **1.82**(a) -195.79°C (b) -320.42°F (c) 5.05 L **1.83**(a) 2.6 m/s (b) 16 km (c) 12:45 pm **1.85** freezing point = -3.7°X; boiling point = 63.3°X **1.86**  $2.3 \times 10^{25} \text{ g}$  oxygen;  $1.4 \times 10^{25} \text{ g}$  silicon;  $5 \times 10^{15} \text{ g}$  ruthenium and rhodium

## Chapter 2

**Answers to Boxed Reading Problems:** **B2.1**(a) 5 peaks (b)  $m/e$  value for heaviest particle = 74;  $m/e$  value for lightest particle = 35 **B2.3**(a) Since salt dissolves in water and pepper does not, add water to mixture and filter to remove solid pepper. Evaporate water to recover solid salt. (b) Distillation purifies the water and leaves

the soot behind. (c) Warm the mixture; filter to remove glass; freeze the filtrate to obtain ice. (d) Heat the mixture; the ethanol will boil off (distill), while the sugar will remain behind. (e) Use column chromatography to separate the pigments.

- **2.1** Compounds contain different types of atoms; there is only one type of atom in an element. **2.4**(a) The presence of more than one element makes pure calcium chloride a compound. (b) There is only one kind of atom, so sulfur is an element. (c) The presence of more than one compound makes baking powder a mixture. (d) The presence of more than one type of atom means cytosine cannot be an element. The specific, not variable, arrangement means it is a compound. **2.12**(a) elements, compounds, and mixtures (b) compounds (c) compounds
- 2.14**(a) Law of definite composition: the composition is the same regardless of its source. (b) Law of mass conservation: the total quantity of matter does not change. (c) Law of multiple proportions: two elements can combine to form two different compounds that have different proportions of those elements. **2.16**(a) No, the percent by mass of each element in a compound is fixed. (b) Yes, the *mass* of each element in a compound depends on the amount of compound. **2.18** The two experiments demonstrate the law of definite composition. The unknown compound decomposes the same way both times. The experiments also demonstrate the law of conservation of mass since the total mass before reaction equals the total mass after reaction. **2.20**(a) 1.34 g F (b) 0.514 Ca; 0.486 F (c) 51.4 mass % Ca; 48.6 mass % F
- 2.22**(a) 0.603 (b) 322 g Mg **2.24**  $3.498 \times 10^6$  g Cu;  $1.766 \times 10^6$  g S
- 2.26** compound 1: 0.905 S/Cl; compound 2: 0.451 S/Cl; ratio: 2.00/1.00 **2.29** Coal A **2.31** Dalton postulated that atoms of an element are identical and that compounds result from the chemical combination of specific ratios of different elements.
- 2.32** If you know the ratio of any two quantities and the value of one of them, the other can always be calculated; in this case, the charge and the mass/charge ratio were known. **2.36** The atomic number is the number of protons in an atom's nucleus. When the atomic number changes, the identity of the element changes. The mass number is the total number of protons and neutrons in the nucleus. The identity of an element is based on the number of protons, not the number of neutrons. The mass number can vary (by a change in number of neutrons) without changing the identity of the element. **2.39** All three isotopes have 18 protons and 18 electrons. Their respective mass numbers are 36, 38, and 40, with the respective numbers of neutrons being 18, 20, and 22.
- 2.41**(a) These have the same number of protons and electrons, but different numbers of neutrons; same *Z*. (b) These have the same number of neutrons, but different numbers of protons and electrons; same *N*. (c) These have different numbers of protons, neutrons, and electrons; same *A*. **2.43**(a)  $^{38}_{18}\text{Ar}$  (b)  $^{55}_{25}\text{Mn}$  (c)  $^{109}_{47}\text{Ag}$
- 2.45**(a)  $^{48}_{22}\text{Ti}$  (b)  $^{79}_{34}\text{Se}$  (c)  $^{11}_{5}\text{B}$

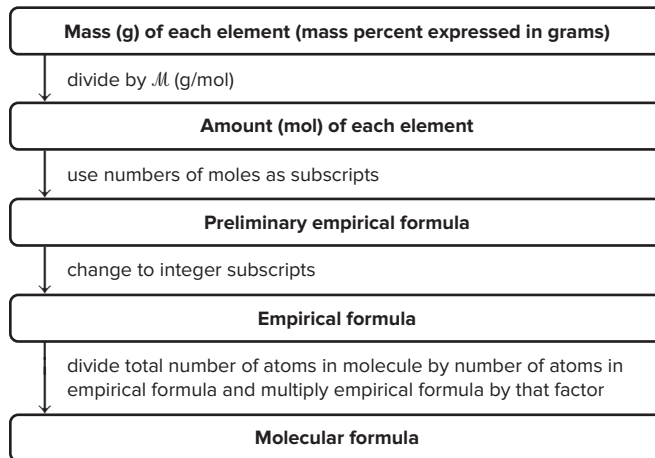

**2.47** 69.72 amu **2.49**  $^{35}\text{Cl} = 75.774\%$ ,  $^{37}\text{Cl} = 24.226\%$

- 2.52**(a) In the modern periodic table, the elements are arranged in order of increasing atomic number. (b) Elements in a group (or family) have similar chemical properties. (c) Elements can be classified as metals, metalloids, or nonmetals. **2.55** The alkali metals [Group 1A(1)] are metals and readily lose one electron to form cations; the halogens [Group 7A(17)] are nonmetals and readily gain one electron to form anions.
- 2.56**(a) germanium; Ge; 4A(14); metalloid (b) phosphorus; P; 5A(15); nonmetal (c) helium; He; 8A(18); nonmetal (d) lithium; Li; 1A(1); metal (e) molybdenum; Mo; 6B(6); metal **2.58**(a) Ra; 88 (b) Si; 14 (c) Cu; 63.55 amu (d) Br; 79.90 amu **2.60** Atoms of these two kinds of substances will form ionic bonds in which one or more electrons are transferred from the metal atom to the nonmetal atom to form a cation and an anion, respectively. **2.63** Coulomb's law states the energy of attraction in an ionic bond is directly proportional to the product of charges and inversely proportional to the distance between charges. The product of charges in MgO [(2+)(2-)] is greater than that in LiF [(1+)(1-)]. Thus, MgO has stronger ionic bonding. **2.66** The Group 1A(1) elements form cations, and the Group 7A(17) elements form anions.
- 2.68** Each potassium atom loses one electron to form an ion with a 1+ charge. Each sulfur atom gains two electrons to form an ion with a 2- charge. Two potassium atoms, losing one electron each, are required for each sulfur atom, which gains two electrons. The oppositely charged ions attract each other to form an ionic solid,  $\text{K}_2\text{S}$ . **2.70**  $\text{K}^+$ ;  $\text{Br}^-$  **2.72**(a) oxygen; 17; 6A(16); 2 (b) fluorine; 19; 7A(17); 2 (c) calcium; 40; 2A(2); 4 **2.74** Lithium forms the  $\text{Li}^+$  ion; oxygen forms the  $\text{O}^{2-}$  ion. Number of  $\text{O}^{2-}$  ions =  $4.2 \times 10^{21}$   $\text{O}^{2-}$  ions. **2.76** NaCl
- 2.78** The subscripts in a formula give the numbers of ions in a formula unit of the compound. The subscripts indicate that there are two  $\text{F}^-$  ions for each  $\text{Mg}^{2+}$  ion. Using this information and the mass of each element, we can calculate percent mass of each element in the compound. **2.80** The two samples are similar in that both contain 20 billion oxygen atoms and 20 billion hydrogen atoms. They differ in that they contain different types of molecules:  $\text{H}_2\text{O}_2$  molecules in the hydrogen peroxide sample, and  $\text{H}_2$  and  $\text{O}_2$  molecules in the mixture. In addition, the mixture contains 20 billion molecules (10 billion  $\text{H}_2$  and 10 billion  $\text{O}_2$ ), while the hydrogen peroxide sample contains 10 billion molecules. **2.84**(a)  $\text{Na}_3\text{N}$ , sodium nitride (b) SrO, strontium oxide (c)  $\text{AlCl}_3$ , aluminum chloride

**3.67** Balance the equation for the reaction:  $aA + bB \longrightarrow cC$ . Since A is the limiting reactant, A is used to determine the amount of C. Divide the mass of A by its molar mass to obtain the amount (mol) of A. Use the molar ratio from the balanced equation to find the amount (mol) of C. Multiply the amount (mol) of C by its molar mass to obtain the mass of C.

## Chapter 4

**4.2** Ionic or polar covalent compounds **4.3** Ions must be present, and they come from electrolytes such as ionic compounds, acids, and bases. **4.6** B **4.13** No, the instructions should read: "Take

100.0 mL of the 10.0 M solution and, with stirring, add water until the total volume is 1000. mL." **4.14(a)** Benzene is likely to be insoluble in water because it is nonpolar and water is polar.

**(b)** Sodium hydroxide, an ionic compound, is likely to be very soluble in water. **(c)** Ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) is likely to be soluble in water because the alcohol group ( $-\text{OH}$ ) is polar, like the water molecule. **(d)** Potassium acetate, an ionic compound, is likely to be very soluble in water. **4.16(a)** Yes,  $\text{CsBr}$  is a soluble salt. **(b)** Yes,  $\text{HI}$  is a strong acid. **4.18(a)** 0.64 mol

your eyes! Pour approximately 2.0 gal of water into the container.

Add to the water, slowly, and with mixing, 0.90 gal of concentrated  $\text{HCl}$ . Dilute to 3.0 gal with more water. **(b)** 22.6 mL

**4.36** Spectator ions do not appear in a net ionic equation because they are not involved in the reaction and serve only to balance charges.

**4.40** Assuming that the left beaker contains  $\text{AgNO}_3$  (because it has gray  $\text{Ag}^+$  ions), the right beaker must contain  $\text{NaCl}$ . Then,  $\text{NO}_3^-$  is blue,  $\text{Na}^+$  is brown, and  $\text{Cl}^-$  is green.

Total ionic:

Spectator ions are  $\text{K}^+$  and  $\text{NO}_3^-$ .

Net ionic: This is the same as the total ionic equation, because there are no spectator ions.

**4.43(a)** No precipitate will form. **(b)** A precipitate will form because silver ions,  $\text{Ag}^+$ , and bromide ions,  $\text{Br}^-$ , will combine to form a solid salt, silver bromide,  $\text{AgBr}$ . The ammonium and nitrate ions do not form a precipitate.

**4.45(a)** No precipitate will form. **(b)**  $\text{BaSO}_4$  will precipitate.

Total ionic:

Net ionic:  $\text{SO}_4^{2-}(aq) + \text{Ba}^{2+}(aq) \longrightarrow \text{BaSO}_4(s)$

**4.47** 0.0354 M  $\text{Pb}^{2+}$  **4.49** 0.88 g  $\text{BaSO}_4$  **4.51(a)**  $\text{PbSO}_4$

(b)  $\text{Pb}^{2+}(aq) + \text{SO}_4^{2-}(aq) \longrightarrow \text{PbSO}_4(s)$  (c) 1.5 g  $\text{PbSO}_4$

**4.53** Potassium carbonate,  $\text{K}_2\text{CO}_3$  **4.55** 2.206 mass %  $\text{Cl}^-$

**4.61(a)** Formation of a gas,  $\text{SO}_2(g)$ , and of a nonelectrolyte, water, will cause the reaction to go to completion. (b) Formation of a precipitate,  $\text{Ba}_3(\text{PO}_4)_2(s)$ , and of a nonelectrolyte, water, will cause the reaction to go to completion. **4.63(a)** 0.035 mol  $\text{H}^+$

(b)  $6.3 \times 10^{-3}$  mol  $\text{H}^+$  (c) 0.22 mol  $\text{H}^+$

**4.65(a)** Molecular equation:

Total ionic equation:

Net ionic equation:  $\text{OH}^-(aq) + \text{H}^+(aq) \longrightarrow \text{H}_2\text{O}(l)$

The spectator ions are  $\text{K}^+(aq)$  and  $\text{Br}^-(aq)$ .

(b) Molecular equation:  $\text{NH}_3(aq) + \text{HCl}(aq) \longrightarrow \text{NH}_4\text{Cl}(aq)$

Total ionic equation:

$\text{NH}_3$ , a weak base, is written in the molecular (undissociated) form.  $\text{HCl}$ , a strong acid, is written as dissociated ions.  $\text{NH}_4\text{Cl}$  is a soluble compound because all ammonium compounds are soluble. Net ionic equation:  $\text{NH}_3(aq) + \text{H}^+(aq) \longrightarrow \text{NH}_4^+(aq)$   $\text{Cl}^-$  is the only spectator ion.

**4.67** Total ionic equation:  $\text{CaCO}_3(s) + 2\text{H}^+(aq) + 2\text{Cl}^-(aq) \longrightarrow$

Net ionic equation:  $\text{CaCO}_3(s) + 2\text{H}^+(aq) \longrightarrow$

**4.69** 845 mL **4.71** 0.05839 M  $\text{CH}_3\text{COOH}$

**4.82(a)** S has O.N. = +6 in  $\text{SO}_4^{2-}$  (i.e.,  $\text{H}_2\text{SO}_4$ ) and O.N. = +4 in  $\text{SO}_2$ , so S has been reduced (and  $\text{I}^-$  oxidized);  $\text{H}_2\text{SO}_4$  acts as an oxidizing agent. (b) The oxidation numbers remain constant throughout;  $\text{H}_2\text{SO}_4$  transfers an  $\text{H}^+$  to  $\text{F}^-$  to produce  $\text{HF}$ , so it acts as an acid. **4.84(a)** +4 (b) +3 (c) +4 (d) -3 **4.86(a)** -1 (b) +2 (c) -3 (d) +3 **4.88(a)** -3 (b) +5 (c) +3 **4.90(a)** +6 (b) +3 (c) +7

**4.92(a)**  $\text{MnO}_4^-$  is the oxidizing agent;  $\text{H}_2\text{C}_2\text{O}_4$  is the reducing agent. (b)  $\text{Cu}$  is the reducing agent;  $\text{NO}_3^-$  is the oxidizing agent.

**4.94(a)** Oxidizing agent is  $\text{MnO}_4^-$ ; reducing agent is  $\text{Sn}$ .

(b) Oxidizing agent is  $\text{NO}_3^-$ ; reducing agent is  $\text{Cl}^-$ .

**4.96(a)**  $4.54 \times 10^{-3}$  mol  $\text{MnO}_4^-$  (b) 0.0113 mol  $\text{H}_2\text{O}_2$  (c) 0.386 g  $\text{H}_2\text{O}_2$  (d) 2.61 mass %  $\text{H}_2\text{O}_2$  (e)  $\text{H}_2\text{O}_2$  **4.102** A combination reaction that is also a redox reaction is  $2\text{Mg}(s) + \text{O}_2(g) \longrightarrow 2\text{MgO}(s)$ .

A combination reaction that is not a redox reaction is

**4.103(a)**  $\text{Ca}(s) + 2\text{H}_2\text{O}(l) \longrightarrow \text{Ca}(\text{OH})_2(aq) + \text{H}_2(g)$ ; displacement

(b)  $2\text{NaNO}_3(s) \longrightarrow 2\text{NaNO}_2(s) + \text{O}_2(g)$ ; decomposition

(c)  $\text{C}_2\text{H}_2(g) + 2\text{H}_2(g) \longrightarrow \text{C}_2\text{H}_6(g)$ ; combination

**4.105(a)**  $2\text{Sb}(s) + 3\text{Cl}_2(g) \longrightarrow 2\text{SbCl}_3(s)$ ; combination

(b)  $2\text{AsH}_3(g) \longrightarrow 2\text{As}(s) + 3\text{H}_2(g)$ ; decomposition

(c)  $\text{Zn}(s) + \text{Fe}(\text{NO}_3)_2(aq) \longrightarrow$

**4.107(a)**  $\text{Sr}(s) + \text{Br}_2(l) \longrightarrow \text{SrBr}_2(s)$

(b)  $2\text{Ag}_2\text{O}(s) \xrightarrow{\Delta} 4\text{Ag}(s) + \text{O}_2(g)$

(c)  $\text{Mn}(s) + \text{Cu}(\text{NO}_3)_2(aq) \longrightarrow \text{Mn}(\text{NO}_3)_2(aq) + \text{Cu}(s)$

### Chapter 6

**Answers to Boxed Reading Problems:** **B6.2**(a)  $2\text{H}_2\text{O}(g) \longrightarrow \text{CH}_4(g) + \text{CO}_2(g)$  (b) 12 kJ (c)  $-3.30 \times 10^4$  kJ

• **6.4** Increase: eating food, lying in the sun, taking a hot bath. Decrease: exercising, taking a cold bath, going outside on a cold day. **6.6** The amount of the change in internal energy is the same for both heater and air conditioner. Since both devices consume the same amount of electrical energy, the change in energy of the heater equals that of the air conditioner. **6.9** 0 J **6.11**  $1.54 \times 10^3$  J **6.13**(a)  $6.6 \times 10^7$  kJ (b)  $1.6 \times 10^7$  kcal (c)  $6.3 \times 10^7$  Btu **6.15**  $-51$  J **6.18** 8.8 h **6.19** Measuring the heat transfer at constant pressure is more convenient than measuring it at constant volume. **6.21**(a) exothermic (b) endothermic (c) exothermic (d) exothermic (e) endothermic (f) endothermic (g) exothermic

**6.26**(a) Combustion of ethane:

(b) Freezing of water:  $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(s) + \text{heat}$

**6.28**(a)  $2\text{CH}_3\text{OH}(l) + 3\text{O}_2(g) \longrightarrow 2\text{CO}_2(g) + 4\text{H}_2\text{O}(g) + \text{heat}$

(b)  $\frac{1}{2}\text{N}_2(g) + \text{O}_2(g) + \text{heat} \longrightarrow \text{NO}_2(g)$

**6.30**(a) This is a phase change from the solid phase to the gas phase. Heat is absorbed by the system, so  $q_{\text{sys}}$  is positive. (b) The volume of the system increases, as more moles of gas are present after the phase change than before. So the system has done work of expansion, and  $w$  is negative. Since  $\Delta E_{\text{sys}} = q + w$ ,  $q$  is positive, and  $w$  is negative, the sign of  $\Delta E_{\text{sys}}$  cannot be predicted. It will be positive if  $q > w$  and negative if  $q < w$ . (c)  $\Delta E_{\text{univ}} = 0$ . If the system loses energy, the surroundings gain an equal quantity of energy. The sum of the energy of the system and the energy of the surroundings remains constant. **6.33** To determine the specific heat capacity of a substance, you need its mass, the heat added (or lost), and the change in temperature. **6.35** Heat capacity is the quantity of heat required to raise the temperature of an object 1 K. Specific heat capacity is the quantity of heat required to raise 1 g of a substance or material by 1 K. Molar heat capacity is the quantity of heat required to raise the temperature of 1 mol of a substance by 1 K. **6.37**  $6.9 \times 10^3$  J **6.39**  $295^{\circ}\text{C}$  **6.41**  $77.5^{\circ}\text{C}$  **6.43**  $45^{\circ}\text{C}$  **6.45**  $36.6^{\circ}\text{C}$  **6.47**  $-55.8$  kJ/mol  $\text{H}_2\text{O}$

**6.49**  $-2805$  kJ/mol **6.55** The reaction has a positive  $\Delta H$ , because it requires an input of energy to break the oxygen-oxygen bond. **6.56**  $\Delta H$  is negative; it is opposite in sign and half as large as  $\Delta H$  for the vaporization of 2 mol of  $\text{H}_2\text{O}$ . **6.57**(a) exothermic (b) 20.2 kJ (c)  $-4.2 \times 10^2$  kJ (d)  $-15.7$  kJ **6.59**(a)  $\frac{1}{2}\text{N}_2(g) + \frac{1}{2}\text{O}_2(g) \longrightarrow \text{NO}(g)$   $\Delta H = 90.29$  kJ (b)  $-10.5$  kJ **6.61**  $-1.88 \times 10^6$  kJ **6.65**(a)  $\text{C}_2\text{H}_4(g) + 3\text{O}_2(g) \longrightarrow 2\text{CO}_2(g) + 2\text{H}_2\text{O}(l)$ ;  $\Delta H_{\text{rxn}} = -1411$  kJ (b) 1.39 g  $\text{C}_2\text{H}_4$

**6.69**  $-110.5 \text{ kJ}$  **6.70**  $-813.4 \text{ kJ}$  **6.72**  $\text{N}_2(\text{g}) + 2\text{O}_2(\text{g}) \longrightarrow 2\text{NO}_2(\text{g})$   
 $\Delta H_{\text{overall}} = 66.4 \text{ kJ}$ ; equation 1 is A, equation 2 is B, and equation 3 is C. **6.74**  $44.0 \text{ kJ}$  **6.77** The standard enthalpy of reaction,  $\Delta H_{\text{rxn}}^\circ$ , is the enthalpy change for a reaction when all substances are in their standard states. The standard enthalpy of formation,  $\Delta H_f^\circ$ , is the enthalpy change that accompanies the formation of 1 mol of a compound in its standard state from elements in their standard states.

(b)  $3.58 \times 10^{-19} \text{ J}$  **7.86(a)** red; green (b)  $5.89 \text{ kJ (Sr)}$ ;  $5.83 \text{ kJ (Ba)}$

**7.88(a)** As the wavelength of maximum absorbance, it provides the highest sensitivity. (b) ultraviolet region (c)  $1.93 \times 10^{-2} \text{ g}$  vitamin A/g oil **7.92**  $1.0 \times 10^{18}$  photons/s **7.95**  $3s \longrightarrow 2p$ ;  
 $3d \longrightarrow 2p$ ;  $4s \longrightarrow 2p$ ;  $3p \longrightarrow 2s$  **7.97**  $133 \text{ nm}$  **7.99(a)**  $1.8 \times 10^{-17} \text{ J}$

(b)  $3.1 \times 10^{-40} \text{ J}$  (c) As the mass of the particle in a box increases, the difference in energy between levels decreases. **7.101** Lowest energy:  $10^{-4} \text{ m}$ ; highest energy:  $10^{-10} \text{ m}$

Chapter 8

8.1 Elements are listed in the periodic table in a systematic way that correlates with a periodicity of their chemical and physical properties. The theoretical basis for the table in terms of sequential atomic number and electron configuration does not allow for a “new element” between Sn and Sb.

8.3(a) predicted atomic mass = 54.23 amu (b) predicted melting point = 6.3°C

8.6 The spin quantum number,  $m_s$ , relates to the electron only; all the others describe the orbital. 8.9 Shielding occurs when electrons protect, or shield, other electrons from the full nuclear attraction. The effective nuclear charge is the nuclear charge an electron actually experiences. As the number of electrons, especially inner electrons, increases, the effective nuclear charge decreases.

8.11(a) 6 (b) 10 (c) 2  
8.13(a) 6 (b) 2 (c) 14 8.16 Hund’s rule states that electrons will occupy empty orbitals in a given sublevel (with parallel spins) before filling half-filled orbitals. The lowest energy arrangement has the maximum number of unpaired electrons with parallel spins.

8.18 Main-group elements from the same group have similar outer electron configurations, and the A-group number equals the number of outer electrons. Outer electron configurations vary in a periodic manner within a period, with each succeeding element having an additional electron. 8.20 The maximum number of electrons in any energy level  $n$  is  $2n^2$ , so the  $n = 4$  energy level holds a maximum of  $2(4^2) = 32$  electrons. 8.21(a)  $n = 5$ ,  $l = 0$ ,  $m_l = 0$ ,  $m_s = +\frac{1}{2}$  (b)  $n = 3$ ,  $l = 1$ ,  $m_l = -1, 0$  or  $+1$ , and  $m_s + \frac{1}{2} =$  or  $-\frac{1}{2}$ . (c)  $n = 5$ ,  $l = 0$ ,  $m_l = 0$ ,  $m_s = +\frac{1}{2}$  (d)  $n = 2$ ,  $l = 1$ ,  $m_l = +1$ ,  $m_s = -\frac{1}{2}$

8.37	Inner Electrons	Outer Electrons	Valence Electrons
(a) O	2	6	6
(b) Sn	46	4	4
(c) Ca	18	2	2
(d) Fe	18	2	8
(e) Se	28	6	6

8.39(a) B; Al, Ga, In, and Tl (b) S; O, Se, Te, and Po (c) La; Sc, Y, and Ac 8.41(a) C; Si, Ge, Sn, and Pb (b) V; Nb, Ta, and Db (c) P; N, As, Sb, and Bi

8.50 A high  $IE_1$  and a very negative  $EA_1$  suggest that the elements are halogens, in Group 7A(17), which form 1− ions.

8.59(a) Na (b) Na (c) Be 8.61(1) Metals conduct electricity; nonmetals do not. (2) Metal ions have a positive charge; nonmetal ions have a negative charge. (3) Metal oxides are mostly ionic and act as bases; nonmetal oxides are mostly covalent and act as acids. 8.62 Metallic character increases down a group and decreases to the right across a period. These trends are the same as those for atomic size and opposite those for ionization energy.

8.65 Possible ions are 2+ and 4+. The 2+ ions form by loss of the outermost two  $p$  electrons; the 4+ ions form by loss of these and the outermost two  $s$  electrons. 8.69(a) Rb (b) Ra (c) I

8.81 a, b, and d 8.83(a)  $V^{3+}$ : [Ar]  $3d^2$ , paramagnetic (b)  $Cd^{2+}$ : [Kr]  $4d^{10}$ , diamagnetic (c)  $Co^{3+}$ : [Ar]  $3d^6$ , paramagnetic (d)  $Ag^+$ : [Kr]  $4d^{10}$ , diamagnetic 8.85 For palladium to be diamagnetic, all of its electrons must be paired. (a) You might first write the condensed electron configuration for Pd as

[Kr]  $5s^2 4d^8$ . However, the partial orbital diagram is not consistent with diamagnetism.

(b) This is the only configuration that supports diamagnetism, [Kr]  $4d^{10}$ .

(c) Promoting an  $s$  electron into the  $d$  sublevel still leaves two electrons unpaired.

**8.87**(a)  $\text{Li}^+ < \text{Na}^+ < \text{K}^+$  (b)  $\text{Rb}^+ < \text{Br}^- < \text{Se}^{2-}$  (c)  $\text{F}^- < \text{O}^{2-} < \text{N}^{3-}$

**8.90** Ce: [Xe]  $6s^2 4f^1 5d^1$ ;  $\text{Ce}^{4+}$ : [Xe]; Eu: [Xe]  $6s^2 4f^7$ ;  $\text{Eu}^{2+}$ : [Xe]  $4f^7$ .  $\text{Ce}^{4+}$  has a noble-gas configuration;  $\text{Eu}^{2+}$  has a half-filled  $f$  subshell.

**8.91**(a)  $\text{Cl}_2\text{O}$ , dichlorine monoxide (b)  $\text{Cl}_2\text{O}_3$ , dichlorine trioxide (c)  $\text{Cl}_2\text{O}_5$ , dichlorine pentoxide (d)  $\text{Cl}_2\text{O}_7$ , dichlorine heptoxide (e)  $\text{SO}_3$ , sulfur trioxide (f)  $\text{SO}_2$ , sulfur dioxide (g)  $\text{N}_2\text{O}_5$ , dinitrogen pentoxide (h)  $\text{N}_2\text{O}_3$ , dinitrogen trioxide (i)  $\text{CO}_2$ , carbon dioxide (j)  $\text{P}_4\text{O}_{10}$ , tetraphosphorus decoxide

**8.94**(a)  $\text{SrBr}_2$ , strontium bromide (b)  $\text{CaS}$ , calcium sulfide (c)  $\text{ZnF}_2$ , zinc fluoride (d)  $\text{LiF}$ , lithium fluoride

**8.95**(a) 2009 kJ/mol (b)  $-549$  kJ/mol **8.97** All ions except  $\text{Fe}^{8+}$  and  $\text{Fe}^{14+}$  are paramagnetic;  $\text{Fe}^+$  and  $\text{Fe}^{3+}$  would be most strongly attracted.

## Chapter 9

**Answers to Boxed Reading Problems: B9.1** The  $\text{C}=\text{C}$  bond shows IR absorption at a shorter wavelength (higher energy) because it is a stronger bond than  $\text{C}-\text{C}$ . The  $\text{C}\equiv\text{C}$  bond would show absorption at a shorter wavelength (higher energy) than the  $\text{C}=\text{C}$  bond, since the triple bond has a higher bond energy than the double bond. **B9.2**(a) 7460 nm (symmetric stretch),  $1.50 \times 10^4$  nm (bending), 4260 nm (asymmetrical stretch) (b)  $2.66 \times 10^{-20}$  J (symmetric stretch),  $1.33 \times 10^{-20}$  J (bending),  $4.67 \times 10^{-20}$  J (asymmetrical stretch); bending requires the least amount of energy.

• **9.1**(a) Greater ionization energy decreases metallic character. (b) Larger atomic radius increases metallic character. (c) Higher number of outer electrons decreases metallic character. (d) Larger effective nuclear charge decreases metallic character. **9.4**(a) Cs (b) Rb (c) As **9.6**(a) ionic (b) covalent (c) metallic **9.8**(a) covalent (b) ionic (c) covalent **9.10**(a)  $\text{Rb}\cdot$  (b)  $\cdot\ddot{\text{S}}\cdot$  (c)  $\cdot\ddot{\text{I}}\cdot$  **9.12**(a)  $\cdot\text{Sr}\cdot$  (b)  $\cdot\ddot{\text{P}}\cdot$  (c)  $\cdot\ddot{\text{S}}\cdot$  **9.14**(a) 6A(16); [noble gas]  $ns^2 np^4$  (b) 3(A)13; [noble gas]  $ns^2 np^1$  **9.17**(a) Because the lattice energy is the result of electrostatic attractions among the oppositely charged ions, its magnitude depends on several factors, including ionic size, ionic charge, and the arrangement of ions in the solid. For a particular arrangement of ions, the lattice energy increases as the charges on the ions increase and as their radii decrease. (b)  $\text{A} < \text{B} < \text{C}$  **9.20**(a)  $\text{Ba}^{2+}$ , [Xe];  $\text{Cl}^-$ , [Ne]  $3s^2 3p^6$ ;  $\cdot\ddot{\text{Cl}}\cdot^-$ ;  $\text{BaCl}_2$  (b)  $\text{Sr}^{2+}$ , [Kr];  $\text{O}^{2-}$ , [He]  $2s^2 2p^6$ ;  $\cdot\ddot{\text{O}}\cdot^{2-}$ ;  $\text{SrO}$  (c)  $\text{Al}^{3+}$ , [Ne];  $\text{F}^-$ , [He]  $2s^2 2p^6$ ;  $\cdot\ddot{\text{F}}\cdot^-$ ;  $\text{AlF}_3$  (d)  $\text{Rb}^+$ , [Kr];  $\text{O}^{2-}$ , [He]  $2s^2 2p^6$ ;  $\cdot\ddot{\text{O}}\cdot^{2-}$ ;  $\text{Rb}_2\text{O}$  **9.22**(a) 2A(2) (b) 6A(16) (c) 1A(1) **9.24**(a) 3A(13) (b) 2A(2) (c) 6A(16) **9.26**(a)  $\text{BaS}$ ; the charge on each ion is twice the charge on the ions in  $\text{CsCl}$ . (b)  $\text{LiCl}$ ;  $\text{Li}^+$  is smaller than

$\text{Cs}^+$ . **9.28**(a)  $\text{BaS}$ ;  $\text{Ba}^{2+}$  is larger than  $\text{Ca}^{2+}$ . (b)  $\text{NaF}$ ; the charge on each ion is less than the charge on  $\text{Mg}$  and  $\text{O}$ . **9.30** 788 kJ; the lattice energy for  $\text{NaCl}$  is less than that for  $\text{LiF}$ , because the  $\text{Na}^+$  and  $\text{Cl}^-$  ions are larger than the  $\text{Li}^+$  and  $\text{F}^-$  ions. **9.33**  $-336$  kJ **9.34** When two chlorine atoms are far apart, there is no interaction between them. As the atoms move closer together, the nucleus of each atom attracts the electrons of the other atom. The closer the atoms, the greater this attraction; however, the repulsions between the two nuclei and between the electrons also increase at the same time. The final internuclear distance is the distance at which maximum attraction is achieved in spite of the repulsions. **9.35** The bond energy is the energy required to break the bond between H atoms and Cl atoms in 1 mol of  $\text{HCl}$  molecules in the gaseous state. Energy is needed to break bonds, so bond breaking is always endothermic and  $\Delta H_{\text{bond breaking}}^\circ$  is positive. The quantity of energy needed to break the bond is released upon its formation, so  $\Delta H_{\text{bond forming}}^\circ$  has the same magnitude as  $\Delta H_{\text{bond breaking}}^\circ$  but is opposite in sign (always exothermic and negative). **9.39**(a)  $\text{I}-\text{I} < \text{Br}-\text{Br} < \text{Cl}-\text{Cl}$  (b)  $\text{S}-\text{Br} < \text{S}-\text{Cl} < \text{S}-\text{H}$  (c)  $\text{C}-\text{N} < \text{C}=\text{N} < \text{C}\equiv\text{N}$  **9.41**(a)  $\text{C}-\text{O} < \text{C}=\text{O}$ ; the  $\text{C}=\text{O}$  bond (bond order = 2) is stronger than the  $\text{C}-\text{O}$  bond (bond order = 1). (b)  $\text{C}-\text{H} < \text{O}-\text{H}$ ; O is smaller than C so the  $\text{O}-\text{H}$  bond is shorter and stronger than the  $\text{C}-\text{H}$  bond. **9.43** Less energy is required to break weak bonds. **9.45** Both are one-carbon molecules. Since methane contains no carbon-oxygen bonds, it will have the greater enthalpy of reaction per mole for combustion.

**9.47**  $-168$  kJ **9.49**  $-22$  kJ **9.50**  $-59$  kJ **9.51** Electronegativity increases from left to right and increases from bottom to top within a group. Fluorine and oxygen are the two most electronegative elements. Cesium and francium are the two least electronegative elements. **9.53** Ionic bonds occur between two elements of very different electronegativity, generally a metal with low electronegativity and a nonmetal with high electronegativity. Although electron sharing occurs to a very small extent in some ionic bonds, the primary force in ionic bonds is attraction of opposite charges resulting from electron transfer between the atoms. A nonpolar covalent bond occurs between two atoms with identical electronegativity values where the sharing of bonding electrons is equal. A polar covalent bond is between two atoms (generally nonmetals) of different electronegativities so that the bonding electrons are unequally shared. The  $\text{H}-\text{O}$  bond in water is polar covalent. The bond is between two nonmetals so it is covalent and not ionic, but atoms with different electronegativity values are involved. **9.56**(a)  $\text{Si} < \text{S} < \text{O}$  (b)  $\text{Mg} < \text{As} < \text{P}$  **9.58**(a)  $\text{N} > \text{P} > \text{Si}$  (b)  $\text{As} > \text{Ga} > \text{Ca}$

**9.62** a, d, and e **9.64**(a) nonpolar covalent (b) ionic (c) polar covalent (d) polar covalent (e) nonpolar covalent (f) polar covalent;  $\text{SCl}_2 < \text{SF}_2 < \text{PF}_3$

**9.69**(a) Shiny, conducts heat, conducts electricity, and is malleable. (b) Metals lose electrons to form positive ions, and metals form basic oxides. **9.73**(a) 800. kJ/mol, which is lower than the value in Table 9.2 (b)  $-2.417 \times 10^4$  kJ (c) 1690. g CO<sub>2</sub> (d) 65.2 L O<sub>2</sub> **9.75**(a)  $-125$  kJ (b) yes, since  $\Delta H_f^\circ$  is negative (c)  $-392$  kJ (d) No,  $\Delta H_f^\circ$  for MgCl<sub>2</sub> is much more negative than that for MgCl. **9.77**(a) 406 nm (b)  $2.93 \times 10^{-19}$  J (c)  $1.87 \times 10^4$  m/s **9.80** C—Cl:  $3.53 \times 10^{-7}$  m; bond in O<sub>2</sub>:  $2.40 \times 10^{-7}$  m **9.81** XeF<sub>2</sub>: 132 kJ/mol; XeF<sub>4</sub>: 150. kJ/mol; XeF<sub>6</sub>: 146 kJ/mol **9.83**(a) The presence of the very electronegative fluorine atoms bonded to one of the carbons makes the C—C bond polar. This polar bond will tend to undergo heterolytic rather than homolytic cleavage. More energy is required to achieve heterolytic cleavage. (b) 1420 kJ **9.86** 13,286 kJ **9.88**  $8.70 \times 10^{14}$  s<sup>-1</sup>;  $3.45 \times 10^{-7}$  m; the UV region **9.90**(a) CH<sub>3</sub>OCH<sub>3</sub>(g):  $-326$  kJ; CH<sub>3</sub>CH<sub>2</sub>OH(g):  $-369$  kJ (b) The formation of gaseous ethanol is more exothermic. (c) 43 kJ

### Chapter 10

**Answers to Boxed Reading Problem: B10.1** resonance form on the left: trigonal planar around C, trigonal pyramidal around N; resonance form on the right: trigonal planar around both C and N.

• **10.1** He cannot serve as a central atom because it does not bond. H cannot because it forms only one bond. Fluorine cannot because it needs only one electron to complete its valence level, and it does not have *d* orbitals available to expand its valence level. Thus, it can bond to only one other atom. **10.3** X obeys the octet rule in all the structures except c and g.

**10.19**(a) B has 6 valence electrons in BH<sub>3</sub>, so the molecule is electron deficient. (b) As has an expanded valence level with 10 electrons. (c) Se has an expanded valence level with 10 electrons.

**10.21**(a) Br expands its valence level to 10 electrons. (b) I has an expanded valence level of 10 electrons. (c) Be has only 4 valence electrons in BeF<sub>2</sub>, so the molecule is electron deficient.

**10.26** structure A **10.28** The molecular shape and the electron-group arrangement are the same when no lone pairs are present on the central atom. **10.30** tetrahedral, AX<sub>4</sub>; trigonal pyramidal, AX<sub>3</sub>E; bent or V shaped, AX<sub>2</sub>E<sub>2</sub>

**10.34**(a) trigonal planar, bent, 120° (b) tetrahedral, trigonal pyramidal, 109.5° (c) tetrahedral, trigonal pyramidal, 109.5°

**10.36**(a) trigonal planar, trigonal planar, 120° (b) trigonal planar, bent, 120° (c) tetrahedral, tetrahedral, 109.5° **10.38**(a) trigonal planar, AX<sub>3</sub>, 120° (b) trigonal pyramidal, AX<sub>3</sub>E, 109.5° (c) trigonal bipyramidal, AX<sub>5</sub>, 90° and 120°

**10.40**(a) bent, 109.5°, less than 109.5° (b) trigonal bipyramidal, 90° and 120°, angles are ideal (c) seesaw, 90° and 120°, less than ideal (d) linear, 180°, angle is ideal

**10.42**(a) C: tetrahedral, 109.5°; O: bent, < 109.5° (b) N: trigonal planar, 120° **10.44**(a) C in CH<sub>3</sub>: tetrahedral, 109.5°; C in C=O: trigonal planar, 120°; O with H: bent, < 109.5° (b) O: bent, < 109.5° **10.46** OF<sub>2</sub> < NF<sub>3</sub> < CF<sub>4</sub> < BF<sub>3</sub> < BeF<sub>2</sub>

**10.48**(a) The C and N each have three electron groups, so the ideal bond angles are 120°; the O has four electron groups, so the ideal bond angle is 109.5°. The N and O have lone pairs, so the bond angles are less than ideal. (b) All central atoms have four electron groups, so the ideal bond angles are 109.5°. The lone pairs on the O reduce this value. (c) The B has three electron groups and an ideal bond angle of 120°. All the O's have four electron groups (ideal bond angles of 109.5°), two of which are lone pairs that reduce the bond angle.

In the gas phase,  $\text{PCl}_5$  is  $\text{AX}_5$ , so the shape is trigonal bipyramidal, and the bond angles are  $120^\circ$  and  $90^\circ$ . The  $\text{PCl}_4^+$  ion is  $\text{AX}_4$ , so the shape is tetrahedral, and the bond angles are  $109.5^\circ$ . The  $\text{PCl}_6^-$  ion is  $\text{AX}_6$ , so the shape is octahedral, and the bond angles are  $90^\circ$ . **10.52** Molecules are polar if they have polar bonds that are not arranged to cancel each other. A polar bond is present any time there is a bond between elements with differing electronegativities. **10.55**(a)  $\text{CF}_4$  (b)  $\text{BrCl}$  and  $\text{SCl}_2$  **10.57**(a)  $\text{SO}_2$ , because it is polar and  $\text{SO}_3$  is not. (b)  $\text{IF}$  has a greater electronegativity difference between its atoms. (c)  $\text{SF}_4$ , because it is polar and  $\text{SiF}_4$  is not. (d)  $\text{H}_2\text{O}$  has a greater electronegativity difference between its atoms.

Yes, compound Y has a dipole moment.

The single  $\text{N}-\text{N}$  bond (bond order = 1) is weaker and longer than the others. The triple bond (bond order = 3) is stronger and shorter than the others. The double bond (bond order = 2) has an intermediate strength and length.

**10.65**(a) formal charges:  $\text{Al} = -1$ , end  $\text{Cl} = 0$ , bridging  $\text{Cl} = +1$ ;  $\text{I} = -1$ , end  $\text{Cl} = 0$ , bridging  $\text{Cl} = +1$  (b) The iodine atoms are each  $\text{AX}_4\text{E}_2$ , and the shape around each is square planar. These square planar portions are adjacent, giving a planar molecule.

**10.70**

(a) In propylene oxide, the shape around each C is tetrahedral, with ideal angles of  $109.5^\circ$ . (b) The C that is not part of the three-membered ring should have close to the ideal angle. The atoms in the ring form an equilateral triangle, so the angles around the two C's in the ring are reduced from the ideal  $109.5^\circ$  to nearly  $60^\circ$ . **10.75**(a)  $-1267 \text{ kJ/mol}$  (b)  $-1226 \text{ kJ/mol}$  (c)  $-1234.8 \text{ kJ/mol}$ . The two answers differ by less than  $10 \text{ kJ/mol}$ . This is very good agreement since average bond energies were used to calculate answers a and b. (d)  $-37 \text{ kJ}$

**10.80**  $\text{CH}_4$ :  $-409 \text{ kJ/mol}$   $\text{O}_2$ ;  $\text{H}_2\text{S}$ :  $-398 \text{ kJ/mol}$   $\text{O}_2$

**10.82**(a) The O in the OH species has only 7 valence electrons, which is less than an octet, and 1 electron is unpaired. (b)  $426 \text{ kJ}$  (c)  $508 \text{ kJ}$  **10.84**(a) The F atoms will substitute at the axial positions first. (b)  $\text{PF}_5$  and  $\text{PCl}_5$

In  $\text{H}_2\text{C}_2\text{O}_4$ , there are two shorter and stronger  $\text{C}=\text{O}$  bonds and two longer and weaker  $\text{C}-\text{O}$  bonds. In  $\text{HC}_2\text{O}_4^-$ , the carbon-oxygen bonds on the side retaining the H remain as one long, weak  $\text{C}-\text{O}$  and one short, strong  $\text{C}=\text{O}$ . The carbon-oxygen bonds on the other side of the molecule have resonance forms with a bond order of 1.5, so they are intermediate in length and strength. In  $\text{C}_2\text{O}_4^{2-}$ , all the carbon-oxygen bonds have a bond order of 1.5. **10.90**  $22 \text{ kJ}$  **10.91** Trigonal planar molecules are nonpolar, so  $\text{AY}_3$  cannot have that shape. Trigonal pyramidal molecules and T-shaped molecules are polar, so  $\text{AY}_3$  could have either of these shapes. **10.95**(a)  $339 \text{ pm}$  (b)  $316 \text{ pm}$  and  $223 \text{ pm}$  (c)  $270 \text{ pm}$

## Chapter 11

**11.1**(a)  $sp^2$  (b)  $sp^3d^2$  (c)  $sp$  (d)  $sp^3$  (e)  $sp^3d$  **11.3** C has only  $2s$  and  $2p$  atomic orbitals, allowing for a maximum of four hybrid orbitals. Si has  $3s$ ,  $3p$ , and  $3d$  atomic orbitals, allowing it to form more than four hybrid orbitals. **11.5**(a) six,  $sp^3d^2$  (b) four,  $sp^3$  **11.7**(a)  $sp^2$  (b)  $sp^2$  (c)  $sp^2$  **11.9**(a)  $sp^3$  (b)  $sp^3$  (c)  $sp^3$  **11.11**(a) Si: one  $s$  and three  $p$  atomic orbitals form four  $sp^3$  hybrid orbitals. (b) C: one  $s$  and one  $p$  atomic orbital form two  $sp$  hybrid orbitals. (c) S: one  $s$ , three  $p$ , and one  $d$  atomic orbital mix to form five  $sp^3d$  hybrid orbitals. (d) N: one  $s$  and three  $p$  atomic orbitals mix to form four  $sp^3$  hybrid orbitals. **11.13**(a) B ( $sp^3 \rightarrow sp^3$ ) (b) A ( $sp^2 \rightarrow sp^3$ )

**11.20**(a) False. A double bond is one  $\sigma$  and one  $\pi$  bond.  
 (b) False. A triple bond consists of one  $\sigma$  and two  $\pi$  bonds.  
 (c) True (d) True (e) False. A  $\pi$  bond consists of one pair of electrons; it occurs after a  $\sigma$  bond has been previously formed.  
 (f) False. End-to-end overlap results in a bond with electron density along the bond axis. **11.21**(a) Nitrogen uses  $sp^2$  to form three  $\sigma$  bonds and one  $\pi$  bond. (b) Carbon uses  $sp$  to form two  $\sigma$  bonds and two  $\pi$  bonds. (c) Carbon uses  $sp^2$  to form three  $\sigma$  bonds and one  $\pi$  bond. **11.23**(a) N:  $sp^2$ , forming two  $\sigma$  bonds and one  $\pi$  bond  $:\ddot{\text{F}}-\ddot{\text{N}}=\ddot{\text{O}}:$

(c) C:  $sp$ , forming two  $\sigma$  bonds and two  $\pi$  bonds  $:\text{N} \equiv \text{C} - \text{C} \equiv \text{N}:$

The single bonds are all  $\sigma$  bonds. The double bond is one  $\sigma$  bond and one  $\pi$  bond. **11.26** Four MOs form from the four  $p$  atomic orbitals. The total number of MOs must equal the number of atomic orbitals. **11.28**(a) Bonding MOs have lower energy than antibonding MOs. Lower energy means more stable. (b) Bonding MOs do not have a node between the nuclei. (c) Bonding MOs have higher electron density between the nuclei than antibonding MOs do. **11.30**(a) two (b) two (c) four **11.32**(a) A is  $\pi_{2p}^*$ , B is  $\sigma_{2p}$ , C is  $\pi_{2p}$ , and D is  $\sigma_{2p}^*$ . (b)  $\pi_{2p}^*$  in A,  $\sigma_{2p}$  in B, and  $\pi_{2p}$  in C have at least one electron. (c)  $\pi_{2p}^*$  in A has only one electron. **11.34**(a) stable (b) paramagnetic (c)  $(\sigma_{2s})^2(\sigma_{2s}^*)^1$  **11.36**(a)  $\text{C}_2^+ < \text{C}_2 < \text{C}_2^-$  (b)  $\text{C}_2^- < \text{C}_2 < \text{C}_2^+$  **11.40**(a) C (ring):  $sp^2$ ; C (all others):  $sp^3$ ; O (all):  $sp^3$ ; N:  $sp^3$  (b) 26 (c) 6 **11.42**(a) 17 (b) All carbons are  $sp^2$ ; the ring N is  $sp^2$ , the other N's are  $sp^3$ . **11.44**(a) B changes from  $sp^2$  to  $sp^3$ . (b) P changes from  $sp^3$  to  $sp^3d$ . (c) C changes from  $sp$  to  $sp^2$ . Two electron groups surround C in  $\text{C}_2\text{H}_2$ , and three electron groups surround C in  $\text{C}_2\text{H}_4$ . (d) Si changes from  $sp^3$  to  $sp^3d^2$ . (e) no change for S **11.46** P: tetrahedral,  $sp^3$ ; N: trigonal pyramidal,  $sp^3$ ;  $\text{C}_1$  and  $\text{C}_2$ : tetrahedral,  $sp^3$ ;  $\text{C}_3$ : trigonal planar,  $sp^2$  **11.51**(a) B and D are present. (b) Yes,  $sp$  hybrid orbitals. (c) Two sets of  $sp$  orbitals, four sets of  $sp^2$  orbitals, and three sets of  $sp^3$  orbitals. **11.52** Through resonance, the C—N bond gains some double-bond character, which hinders rotation about that bond.

**11.56**(a) C in  $-\text{CH}_3$ :  $sp^3$ ; all other C atoms:  $sp^2$ ; O in two C—O bonds:  $sp^3$ ; O in two C=O bonds:  $sp^2$  (b) two (c) eight; one **11.57**(a) four (b) eight

## Chapter 12

**Answer to Boxed Reading Problem: B12.1**  $1.76 \times 10^{-10}$  m

• **12.1** In a solid, the energy of attraction of the particles is greater than their energy of motion; in a gas, it is less. Gases have high compressibility and the ability to flow, while solids have neither. **12.4**(a) Because the intermolecular forces are only partially overcome when fusion occurs but need to be totally overcome in vaporization. (b) Because solids have greater intermolecular forces than liquids do. (c)  $\Delta H_{\text{vap}} = -\Delta H_{\text{cond}}$  **12.5**(a) intermolecular (b) intermolecular (c) intramolecular (d) intramolecular **12.7**(a) condensation (b) fusion (c) vaporization **12.9** The gas molecules slow down as the gas is compressed. Therefore, much of the kinetic energy lost by the propane molecules is released to the surroundings. **12.13** At first, the vaporization of liquid molecules from the surface predominates, which increases the number of gas molecules and hence the vapor pressure. As more molecules enter the gas phase, more gas molecules hit the surface of the liquid and “stick” more frequently, so the condensation rate increases. When the vaporization and condensation rates become equal, the vapor pressure remains constant. **12.14** As the strength of intermolecular forces increases, (a) critical temperature increases, (b) boiling point increases, (c) vapor pressure decreases, and (d) heat of vaporization increases. **12.18** because the condensation of the vapor supplies an additional 40.7 kJ/mol **12.19**  $7.67 \times 10^3$  J **12.21** 0.777 atm **12.23**  $2 \times 10^4$  J/mol

**12.25**

Solid ethylene is more dense than liquid ethylene.

**12.27**(a) Rhombic sulfur will sublime when it is heated at a pressure less than  $1 \times 10^{-4}$  atm. (b) At  $90^\circ\text{C}$  and 1 atm, sulfur is in the solid (rhombic) form. As it is heated at constant pressure, it passes through the solid (monoclinic) phase, starting at  $114^\circ\text{C}$ . At about  $120^\circ\text{C}$ , the solid melts to form the liquid. At about  $445^\circ\text{C}$ , the liquid evaporates and changes to the gas. **12.30** 32 atm **12.34** O is smaller and more electronegative than Se; thus, the electron density of O is greater, which attracts H more strongly. **12.36** All particles (atoms and molecules) exhibit dispersion forces, but the total force is weak for small molecules. Dipole-dipole forces between small polar molecules dominate dispersion forces between those molecules. **12.39**(a) hydrogen bonding (b) dispersion forces (c) dispersion forces **12.41**(a) dipole-dipole forces (b) dispersion forces (c) H bonding

**12.43**(a)

**12.45**(a) dispersion forces (b) H bonding (c) dispersion forces  
**12.47**(a)  $\text{I}^-$  (b)  $\text{CH}_2=\text{CH}_2$  (c)  $\text{H}_2\text{Se}$ . In (a) and (c) the larger particle has the higher polarizability. In (b), the less tightly held  $\pi$  electron clouds are more easily distorted. **12.49**(a)  $\text{C}_2\text{H}_6$ ; it is a smaller molecule exhibiting weaker dispersion forces than  $\text{C}_4\text{H}_{10}$ . (b)  $\text{CH}_3\text{CH}_2\text{F}$ ; it has no H—F bonds, so it exhibits only dipole-dipole forces, which are weaker than the H bonds of  $\text{CH}_3\text{CH}_2\text{OH}$ . (c)  $\text{PH}_3$ ; it has weaker intermolecular forces (dipole-dipole) than  $\text{NH}_3$  (hydrogen bonding). **12.51**(a)  $\text{HCl}$ ; it has dipole-dipole forces, and there is stronger ionic bonding in  $\text{LiCl}$ . (b)  $\text{PH}_3$ ; it has dipole-dipole forces, and there is stronger H bonding in  $\text{NH}_3$ . (c)  $\text{Xe}$ ; it exhibits weaker dispersion forces since its smaller size results in lower polarizability than for the larger  $\text{I}_2$  molecules. **12.53**(a)  $\text{C}_4\text{H}_8$  (cyclobutane), because it is more compact than  $\text{C}_4\text{H}_{10}$ . (b)  $\text{PBr}_3$ ; the dipole-dipole forces in  $\text{PBr}_3$  are weaker than the ionic bonds in  $\text{NaBr}$ . (c)  $\text{HBr}$ ; the dipole-dipole forces in  $\text{HBr}$  are weaker than the H bonds in water. **12.55** As atomic size decreases and electronegativity increases, the electron density of an atom increases. Thus, the attraction to an H atom on another molecule increases while its bonded H atom becomes more positive. Fluorine is the smallest of the three and the most electronegative, so the H bonds in hydrogen fluoride are the strongest. Oxygen is smaller and more electronegative than nitrogen, so H bonds in water are stronger than H bonds in ammonia. **12.59** The cohesive forces in water and mercury are stronger than the adhesive forces to the nonpolar wax on the floor. Weak adhesive forces result in spherical drops. The adhesive forces overcome the even weaker cohesive forces in the oil, and so the oil drop spreads out. **12.61** Surface tension is defined as the energy needed to increase the surface area by a given amount, so units of energy per area are appropriate. **12.63**  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH} < \text{HOCH}_2\text{CH}_2\text{OH} < \text{HOCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH}$ . More H bonding means greater attraction between molecules, so more energy is needed to increase surface area. **12.65**  $\text{HOCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH} > \text{HOCH}_2\text{CH}_2\text{OH} > \text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ . More H bonding means greater attraction between molecules, so the liquid flows less easily. **12.70** Water is a good solvent for polar and ionic substances and a poor solvent for nonpolar substances. Water is a polar molecule and dissolves polar substances because their intermolecular forces are of similar strength. **12.71** A single water molecule can form four H bonds. The two hydrogen atoms each form one H bond to oxygen atoms on neighboring water molecules. The two lone pairs on the oxygen atom form H bonds with hydrogen atoms on two neighboring molecules. **12.74** Water exhibits strong capillary action, which allows it to be easily absorbed by the plant's roots and transported upward to the leaves. **12.80** simple cubic **12.83** The energy gap is the energy difference between the highest filled energy level (valence band) and the lowest unfilled energy level (conduction band). In conductors and superconductors, the energy gap is zero because the valence band overlaps the conduction band. In semiconductors, the energy gap is small. In insulators, the gap is large. **12.85** atomic mass and atomic radius **12.86**(a) face-centered cubic (b) body-centered cubic (c) face-centered cubic **12.88**  $1.54 \text{ g/cm}^3$  **12.90**(a) The change in unit cell is from a sodium chloride structure in  $\text{CdO}$  to a zinc blende structure in  $\text{CdSe}$ . (b) Yes, the coordination number

of Cd changes from 6 in  $\text{CdO}$  to 4 in  $\text{CdSe}$ . **12.92** 524 pm  
**12.94**(a) Nickel forms a metallic solid since it is a metal whose atoms are held together by metallic bonds. (b) Fluorine forms a molecular solid since the  $\text{F}_2$  molecules are held together by dispersion forces. (c) Methanol forms a molecular solid since the  $\text{CH}_3\text{OH}$  molecules are held together by H bonds. (d) Tin forms a metallic solid since it is a metal whose atoms are held together by metallic bonds. (e) Silicon is under carbon in Group 4A(14); it exhibits similar bonding properties to carbon. Since diamond and graphite are both network covalent solids, it makes sense that Si forms a network covalent solid as well. (f) Xe is an atomic solid since its individual atoms are held together by dispersion forces. **12.96** four **12.98**(a) four  $\text{Se}^{2-}$  ions, four  $\text{Zn}^{2+}$  ions (b) 577.48 amu (c)  $1.77 \times 10^{-22} \text{ cm}^3$  (d)  $5.61 \times 10^{-8} \text{ cm}$   
**12.100**(a) insulator (b) conductor (c) semiconductor  
**12.102**(a) Conductivity increases. (b) Conductivity increases. (c) Conductivity decreases. **12.104**  $1.68 \times 10^{-8} \text{ cm}$  **12.111** A substance whose properties are the same in all directions is isotropic; otherwise, the substance is anisotropic. Liquid crystals have a degree of order only in certain directions, so they are anisotropic. **12.117**(a) n-type semiconductor (b) p-type semiconductor **12.119**  $n = 3.4 \times 10^3$  **12.121** 8.4 pm  
**12.124**(a) 19.8 torr (b) 0.0485 g **12.130** 259 K ( $-14^\circ\text{C}$ )  
**12.132**(a)  $2.23 \times 10^{-2} \text{ atm}$  (b) 6.23 L

**12.135**(a) furfuryl alcohol

2-furoic acid

(b) furfuryl alcohol

2-furoic acid

**12.136**(a) 49.3 metric tons  $\text{H}_2\text{O}$  (b)  $-1.11 \times 10^8 \text{ kJ}$  **12.137**  $2.9 \text{ g/m}^3$   
**12.142**(a) 1.1 min (b) 10. min

**12.143**  $2.98 \times 10^5 \text{ g BN}$  **12.146** 45.98 amu

## Chapter 13

**Answer to Boxed Reading Problem: B13.1**(a) The colloidal particles in water generally have negatively charged surfaces and so repel each other, slowing the settling process. Cake alum,  $\text{Al}_2(\text{SO}_4)_3$ , is added to coagulate the colloids. The  $\text{Al}^{3+}$  ions neutralize the negative surface charges on the particles, allowing them to aggregate and settle. (b) Water that contains large amounts of divalent cations (such as  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ ) is called hard water. If this water is used for cleaning, these ions combine with the fatty-acid anions in soaps to produce insoluble deposits. (c) In reverse osmosis, a pressure greater than the osmotic pressure is applied to the solution, forcing the water back through the membrane, leaving the ions behind. (d) Chlorine may give the water an unpleasant odor, and it can form carcinogenic chlorinated organic compounds. (e) The high concentration of  $\text{Na}^+$  in the saturated solution of  $\text{NaCl}$  displaces the divalent and polyvalent ions from the ion-exchange resin.

• **13.2** When a salt such as  $\text{NaCl}$  dissolves, ion-dipole forces cause the ions to separate, and many water molecules cluster around each ion in hydration shells. Ion-dipole forces bind the first shell to an ion. The water molecules in that shell form H bonds to others to create the next shell, and so on. **13.4** Sodium stearate is a more effective soap because the hydrocarbon chain in the stearate ion is longer than that in the acetate ion. The longer chain increases dispersion forces with grease molecules. **13.7**  $\text{KNO}_3$  is an ionic compound and is therefore more soluble in water than in carbon tetrachloride. **13.9**(a) ion-dipole forces (b) H bonding (c) dipole-induced dipole forces **13.11**(a) H bonding (b) dipole-induced dipole forces (c) dispersion forces **13.13**(a)  $\text{HCl}(g)$ , because the molecular interactions (dipole-dipole forces) in ether are more like those in  $\text{HCl}$  than is the ionic bonding in  $\text{NaCl}$ . (b)  $\text{CH}_3\text{CHO}(l)$ , because the molecular interactions with ether (dipole-dipole forces) can replace those between  $\text{CH}_3\text{CHO}$  molecules, but not the H bonds between water molecules. (c)  $\text{CH}_3\text{CH}_2\text{MgBr}(s)$ , because the molecular interactions (dipole-dipole and dispersion forces) with ether are greater than those between ether molecules and the ions in  $\text{MgBr}_2$ . **13.16** Gluconic acid is soluble in water due to the extensive H bonding involving the  $-\text{OH}$  groups attached to five of its carbons. The dispersion forces involving the nonpolar tails of caproic acid are more similar to the dispersion forces in hexane; thus, caproic acid is soluble in hexane. **13.18** The nitrogen-containing bases form H bonds to their complementary bases. The flat, N-containing bases stack above each other, which allows extensive dispersion forces. The exterior, negatively charged, sugar-phosphate chains experience ion-dipole forces and form H bonds with water molecules in the aqueous surroundings, which also stabilizes the structure. **13.21** Dispersion forces are present between the nonpolar tails of the lipid molecules within the bilayer. The polar heads interact with the aqueous surroundings through H bonds and ion-dipole forces. **13.25** The enthalpy changes needed to separate the solvent particles ( $\Delta H_{\text{solvent}}$ ) and to mix the solvent and solute particles ( $\Delta H_{\text{mix}}$ ) combine to give  $\Delta H_{\text{solvation}}$ . **13.29** The compound is very soluble in water, because a decrease in enthalpy and an increase in entropy both favor the formation of a solution.

**13.32**(a) The volume of  $\text{Na}^+$  is smaller. (b)  $\text{Sr}^{2+}$  has a larger ionic charge and a smaller volume. (c)  $\text{Na}^+$  is smaller than  $\text{Cl}^-$ . (d)  $\text{O}^{2-}$  has a larger ionic charge. (e)  $\text{OH}^-$  has a smaller volume than  $\text{SH}^-$ . (f)  $\text{Mg}^{2+}$  has a smaller volume. (g)  $\text{Mg}^{2+}$  has both a smaller volume and a larger ionic charge. (h)  $\text{CO}_3^{2-}$  has a larger ionic charge. **13.34**(a)  $\text{Na}^+$  (b)  $\text{Sr}^{2+}$  (c)  $\text{Na}^+$  (d)  $\text{O}^{2-}$  (e)  $\text{OH}^-$  (f)  $\text{Mg}^{2+}$  (g)  $\text{Mg}^{2+}$  (h)  $\text{CO}_3^{2-}$  **13.36**(a)  $-704 \text{ kJ/mol}$  (b) The  $\text{K}^+$  ion contributes more because it is smaller and, therefore, has a greater charge density. **13.38**(a) increases (b) decreases (c) increases **13.41** Add a pinch of X to each solution. Addition of a “seed” crystal of solute to a supersaturated solution causes the excess solute to crystallize immediately, leaving behind a saturated solution. The solution in which the added X dissolves is the unsaturated solution. The solution in which the added X remains undissolved is the saturated solution. **13.44**(a) increase (b) decrease **13.46**(a)  $0.102 \text{ g O}_2$  (b)  $0.0214 \text{ g O}_2$  **13.49**  $0.20 \text{ mol/L}$  **13.52**(a) molarity and % w/v or % v/v (b) parts-by-mass (% w/w) (c) molality **13.54** With just this information, you can convert between molality and molarity, but you need to know the molar mass of the solvent to convert to mole fraction. **13.56**(a)  $0.944 \text{ M C}_{12}\text{H}_{22}\text{O}_{11}$  (b)  $0.167 \text{ M LiNO}_3$  **13.58**(a)  $0.0749 \text{ M NaOH}$  (b)  $0.36 \text{ M HNO}_3$  **13.60**(a) Add  $4.25 \text{ g KH}_2\text{PO}_4$  to enough water to make  $365 \text{ mL}$  of aqueous solution. (b) Add  $125 \text{ mL}$  of  $1.25 \text{ M NaOH}$  to enough water to make  $465 \text{ mL}$  of solution. **13.62**(a) Weigh out  $48.0 \text{ g KBr}$ , dissolve it in about  $1 \text{ L}$  distilled water, and then dilute to  $1.40 \text{ L}$  with distilled water. (b) Measure  $82.7 \text{ mL}$  of the  $0.264 \text{ M LiNO}_3$  solution and add distilled water to make a total of  $255 \text{ mL}$ . **13.64**(a)  $0.896 \text{ m glycine}$  (b)  $1.21 \text{ m glycerol}$  **13.66**  $4.48 \text{ m C}_6\text{H}_6$  **13.68**(a) Add  $2.39 \text{ g C}_2\text{H}_6\text{O}_2$  to  $308 \text{ g H}_2\text{O}$ . (b) Add  $0.0508 \text{ kg}$  of  $52.0\% \text{ HNO}_3$  by mass to  $1.15 \text{ kg H}_2\text{O}$  to make  $1.20 \text{ kg}$  of  $2.20\% \text{ HNO}_3$  by mass. **13.70**(a)  $0.29$  (b)  $58 \text{ mass } \%$  (c)  $23 \text{ m C}_3\text{H}_7\text{OH}$  **13.72**  $42.6 \text{ g CsBr}$ ; mole fraction =  $7.16 \times 10^{-3}$ ;  $7.84\% \text{ by mass}$  **13.74**  $5.11 \text{ m NH}_3$ ;  $4.53 \text{ M NH}_3$ ; mole fraction =  $0.0843$  **13.76**  $2.5 \text{ ppm Ca}^{2+}$ ;  $0.56 \text{ ppm Mg}^{2+}$  **13.80** Its solution conducts a “strong” current. A strong electrolyte dissociates completely into ions in solution. **13.82** The boiling point is higher and the freezing point is lower for the solution than for the pure solvent. **13.85** A dilute solution of an electrolyte behaves more ideally than a concentrated one. With increasing concentration, the effective concentration deviates from the molar concentration because of ionic attractions. Thus,  $0.050 \text{ m NaF}$  has a boiling point closer to its predicted value. **13.88**(a) strong electrolyte (b) strong electrolyte (c) nonelectrolyte (d) weak electrolyte **13.90**(a)  $0.6 \text{ mol}$  of solute particles (b)  $0.13 \text{ mol}$  (c)  $2 \times 10^{-4} \text{ mol}$  (d)  $0.06 \text{ mol}$  **13.92**(a)  $\text{CH}_3\text{OH}$  in  $\text{H}_2\text{O}$  (b)  $\text{H}_2\text{O}$  in  $\text{CH}_3\text{OH}$  solution **13.94**(a)  $\Pi_{\text{II}} < \Pi_{\text{I}} < \Pi_{\text{III}}$  (b)  $\text{bp}_{\text{II}} < \text{bp}_{\text{I}} < \text{bp}_{\text{III}}$  (c)  $\text{fp}_{\text{III}} < \text{fp}_{\text{I}} < \text{fp}_{\text{II}}$  (d)  $\text{vp}_{\text{III}} < \text{vp}_{\text{I}} < \text{vp}_{\text{II}}$  **13.96**  $23.4 \text{ torr}$  **13.98**  $-0.467^\circ\text{C}$  **13.100**  $79.5^\circ\text{C}$  **13.102**  $1.18 \times 10^4 \text{ g C}_2\text{H}_6\text{O}_2$

- 13.104**  $2.44 \times 10^{-3}$  atm **13.106** 342 g/mol **13.108**  $-14.6^\circ\text{C}$   
**13.110**(a) NaCl: 0.173 *m* and  $i = 1.84$  (b)  $\text{CH}_3\text{COOH}$ : 0.0837 *m*  
 and  $i = 1.02$  **13.113** 209 torr for  $\text{CH}_2\text{Cl}_2$ ; 48.1 torr for  $\text{CCl}_4$   
**13.114** The fluid inside a bacterial cell is both a solution and a  
 colloid. It is a solution of ions and small molecules and a colloid  
 of large molecules (proteins and nucleic acids). **13.118** Soap  
 micelles have nonpolar tails pointed inward and anionic heads  
 pointed outward. The like charges on the heads of one micelle  
 repel those on the heads of a neighboring micelle. This repulsion  
 between micelles keeps them from coagulating. Soap is more  
 effective in freshwater than in seawater because the divalent  
 cations in seawater combine with the anionic heads to form a  
 precipitate. **13.122**  $3.4 \times 10^9$  L **13.126**  $0.0^\circ\text{C}$ :  $4.53 \times 10^{-4}$  *M*  $\text{O}_2$ ;  
 $20.0^\circ\text{C}$ :  $2.83 \times 10^{-4}$  *M*  $\text{O}_2$ ;  $40.0^\circ\text{C}$ :  $2.00 \times 10^{-4}$  *M*  $\text{O}_2$   
**13.128**(a) 89.9 g/mol (b)  $\text{C}_2\text{H}_5\text{O}$ ;  $\text{C}_4\text{H}_{10}\text{O}_2$

- 13.132**(a) 9.45 g NaF (b) 0.0017 g  $\text{F}^-$  **13.135**(a) 68 g/mol  
 (b)  $2.1 \times 10^2$  g/mol (c) The molar mass of  $\text{CaN}_2\text{O}_6$  is 164.10 g/mol.  
 This value is less than the  $2.1 \times 10^2$  g/mol calculated when the  
 compound is assumed to be a strong electrolyte and is greater than  
 the 68 g/mol calculated when the compound is assumed to be a  
 nonelectrolyte. Thus, the compound forms a nonideal solution  
 because the ions interact and therefore do not dissociate completely  
 in solution. (d)  $i = 2.4$  **13.139**(a)  $1.82 \times 10^4$  g/mol (b)  $3.41 \times 10^{-5}$   $^\circ\text{C}$   
**13.140**  $8.2 \times 10^5$  ng/L **13.144**(a) 0.02 (b)  $5 \times 10^{-3}$  atm·L/mol (c) yes  
**13.146** Weigh 3.11 g of  $\text{NaHCO}_3$  and dissolve in 247 g of water.  
**13.150**  $M = m(\text{kg solvent/L solution}) = m \times d_{\text{solution}}$ . Thus, for  
 very dilute solutions, molality  $\times$  density = molarity. For an aqueous  
 solution, the number of liters of solution is approximately the same  
 as the kg of solvent because the density of water is close to  
 1 kg/L, so  $m = M$ . **13.152**(a)  $2.5 \times 10^{-3}$  *M*  $\text{SO}_2$  (b) The base  
 reacts with the sulfur dioxide to produce calcium sulfite. This  
 removal of sulfur dioxide allows more sulfur dioxide to dissolve.  
**13.157**(a)  $7.83 \times 10^{-3}$  mol/L·atm (b)  $4 \times 10^{-5}$  *M* (c)  $3 \times 10^{-6}$  (d) 1 ppm  
**13.161**(a) 0.0212 mol/L·atm (b) 8.86 ppm (c)  $k_{\text{H}}$ :  $\text{C}_6\text{F}_{14} > \text{C}_6\text{H}_{14}$   
 $>$  ethanol  $>$  water. To dissolve oxygen in a solvent, the solvent  
 molecules must be moved apart to make room for the gas. The  
 stronger the intermolecular forces in the solvent, the more  
 difficult it is to separate solvent particles and the lower the  
 solubility of the gas. Both  $\text{C}_6\text{F}_{14}$  and  $\text{C}_6\text{H}_{14}$  have weak dispersion  
 forces, with  $\text{C}_6\text{F}_{14}$  having the weaker forces due to the electro-  
 negative fluorine atoms repelling each other. In both ethanol and  
 water, the molecules are held together by strong H bonds with  
 those bonds being stronger in water, as the boiling point indicates.  
**13.163**(a) Yes, the phases of water can still coexist at some  
 temperature and can therefore establish equilibrium. (b) The  
 triple point would occur at a lower pressure and lower tempera-  
 ture because the dissolved air would lower the vapor pressure of  
 the solvent. (c) Yes, this is possible because the gas-solid phase  
 boundary exists below the new triple point. (d) No; at both  
 temperatures, the presence of the solute lowers the vapor  
 pressure of the liquid. **13.165**(a)  $2.8 \times 10^{-4}$  g/mL (b) 81 mL

## Chapter 14

**14.1** The outermost electron is attracted by a smaller effective  
 nuclear charge in Li because of shielding by the inner electrons,  
 and it is farther from the nucleus than the electron of H is. Both  
 of these factors lead to a lower ionization energy for Li.

**14.3**(a)  $\text{NH}_3$  will hydrogen bond.

(b)  $\text{CH}_3\text{CH}_2\text{OH}$  will hydrogen bond.

**14.5**(a)  $2\text{Al}(s) + 6\text{HCl}(aq) \rightarrow 2\text{AlCl}_3(aq) + 3\text{H}_2(g)$

(b)  $\text{LiH}(s) + \text{H}_2\text{O}(l) \rightarrow \text{LiOH}(aq) + \text{H}_2(g)$

**14.7**(a)  $\text{NaBH}_4$ : +1 for Na, +3 for B, -1 for H;  $\text{Al}(\text{BH}_4)_3$ : +3 for  
 Al, +3 for B, -1 for H;  $\text{LiAlH}_4$ : +1 for Li, +3 for Al, -1 for  
 H (b) tetrahedral

**14.10** For Groups 1A(1) to 4A(14), the number of covalent bonds  
 equals the A-group number. For Groups 5A(15) to 7A(17), it  
 equals 8 minus the A-group number. There are exceptions in  
 Period 3 to Period 6 because it is possible for the 3A(13) to 7A(17)  
 elements to use *d* orbitals and form more bonds. **14.13**(a) Group  
 3A(13) or 3B(3) (b) If E is in Group 3B(3), the oxide will be  
 more basic and the fluoride will be more ionic; if E is in Group  
 3A(13), the oxide will be more acidic and the fluoride will be  
 more covalent. **14.16**(a) reducing agent (b) Alkali metals have  
 relatively low ionization energies, which means they easily lose  
 the outermost electron.

(c)  $2\text{Na}(s) + 2\text{H}_2\text{O}(l) \rightarrow 2\text{Na}^+(aq) + 2\text{OH}^-(aq) + \text{H}_2(g)$

$2\text{Na}(s) + \text{Cl}_2(g) \rightarrow 2\text{NaCl}(s)$

**14.18** Density and ionic size increase down a group; the other  
 three properties decrease down a group.

**14.20**  $2\text{Na}(s) + \text{O}_2(g) \rightarrow \text{Na}_2\text{O}_2(s)$

**14.22**  $\text{K}_2\text{CO}_3(s) + 2\text{HI}(aq) \rightarrow 2\text{KI}(aq) + \text{H}_2\text{O}(l) + \text{CO}_2(g)$

**14.26** Group 2A(2) metals have an additional valence electron to  
 increase the strength of metallic bonding, which leads to higher  
 melting points, and also higher boiling points, greater hardness,  
 and greater density.

**14.27**(a)  $\text{CaO}(s) + \text{H}_2\text{O}(l) \rightarrow \text{Ca}(\text{OH})_2(s)$

(b)  $2\text{Ca}(s) + \text{O}_2(g) \rightarrow 2\text{CaO}(s)$

**14.30**(a)  $\text{BeO}(s) + \text{H}_2\text{O}(l) \rightarrow$  no reaction

(b)  $\text{BeCl}_2(l) + 2\text{Cl}^-(\text{solvated}) \rightarrow \text{BeCl}_4^{2-}(\text{solvated})$

Be behaves like other Group 2A(2) elements in reaction (b).

**14.33** The electron removed from Group 2A(2) atoms occupies  
 the outer *s* orbital, whereas in Group 3A(13) atoms, the electron  
 occupies the outer *p* orbital. For example, the electron configura-  
 tion for Be is  $1s^2 2s^2$  and for B it is  $1s^2 2s^2 2p^1$ . It is easier to  
 remove the *p* electron of B than an *s* electron of Be, because the  
 energy of a *p* orbital is higher than that of the *s* orbital of the  
 same level. Even though atomic size decreases because of  
 increasing  $Z_{\text{eff}}$ , IE decreases from 2A(2) to 3A(13).

**14.34**(a) Most atoms form stable compounds when they complete  
 their outer shell (octet). Some compounds of Group 3A(13)  
 elements, like boron, have only six electrons around the central

atom. Having fewer than eight electrons is called *electron deficiency*.

**14.36**  $\text{In}_2\text{O}_3 < \text{Ga}_2\text{O}_3 < \text{Al}_2\text{O}_3$  **14.38** Apparent O.N., +3; actual O.N., +1.  $[\text{I}^+ - \text{I}^- - \text{I}^-]^-$  The anion  $\text{I}_3^-$  has the general formula  $\text{AX}_2\text{E}_3$  and bond angles of  $180^\circ$ .  $(\text{TI}^{3+})(\text{I}^-)_3$  does not exist because of the low strength of the  $\text{TI}-\text{I}$  bond.

(b)  $1.30 \times 10^2$  kJ (c) 5.3 kg borax **14.44** Basicity in water is greater for the oxide of a metal. Tin(IV) oxide is more basic in water than carbon dioxide because tin has more metallic character than carbon. **14.46**(a) Ionization energy generally decreases down a group. (b) The deviations (increases) from the expected trend are due to the presence of the first transition series between Si and Ge and of the lanthanides between Sn and Pb. (c) Group 3A(13) **14.49** Atomic size increases down a group. As atomic size increases, ionization energy decreases, and so it is easier to form a positive ion. An atom that is easier to ionize exhibits greater metallic character.

**14.54**(a) diamond, C (b) calcium carbonate,  $\text{CaCO}_3$  (c) carbon dioxide,  $\text{CO}_2$  (d) carbon monoxide, CO (e) silicon, Si

**14.58**(a)  $-3$  to  $+5$  (b) For a group of nonmetals, the oxidation states range from the lowest, equal to the A-group number  $-8$ , or  $5 - 8 = -3$  for Group 5A, to the highest, equal to the A-group number, or  $+5$  for Group 5A.

**14.67** trigonal bipyramidal, with axial F atoms and equatorial Cl atoms;

**14.75**(a) Boiling point and conductivity vary in similar ways down both groups. (b) Degree of metallic character and types of bonding vary in similar ways down both groups. (c) Both P and S have allotropes, and both bond covalently with almost every other non-metal. (d) Both N and O are diatomic gases at normal temperatures and pressures. (e)  $\text{O}_2$  is a reactive gas, whereas  $\text{N}_2$  is not. Nitrogen can have any of six oxidation states, whereas oxygen has two.

**14.79**(a) acidic (b) acidic (c) basic (d) amphoteric (e) basic

**14.81**  $\text{H}_2\text{O} < \text{H}_2\text{S} < \text{H}_2\text{Te}$  **14.84**(a)  $\text{O}_3$ , ozone (b)  $\text{SO}_3$ , sulfur trioxide (c)  $\text{SO}_2$ , sulfur dioxide (d)  $\text{H}_2\text{SO}_4$ , sulfuric acid

(e)  $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ , sodium thiosulfate pentahydrate

**14.86**  $\text{S}_2\text{F}_{10}(\text{g}) \longrightarrow \text{SF}_4(\text{g}) + \text{SF}_6(\text{g})$ ; O.N. of S in  $\text{S}_2\text{F}_{10}$  is  $+5$ ; O.N. of S in  $\text{SF}_4$  is  $+4$ ; O.N. of S in  $\text{SF}_6$  is  $+6$ . **14.88**(a)  $-1$ ,  $+1$ ,  $+3$ ,  $+5$ ,  $+7$  (b) The electron configuration for Cl is  $[\text{Ne}] 3s^2 3p^5$ . By gaining one electron, Cl achieves an octet. When forming covalent bonds, Cl completes or expands its valence level by maintaining electron pairs in bonds or as lone pairs. (c) Fluorine has only the  $-1$  oxidation state because its small size and absence of  $d$  orbitals prevent it from forming more than one covalent bond. **14.90**(a)  $\text{Cl}-\text{Cl}$  bond is stronger than  $\text{Br}-\text{Br}$  bond. (b)  $\text{Br}-\text{Br}$  bond is stronger than  $\text{I}-\text{I}$  bond. (c)  $\text{Cl}-\text{Cl}$  bond is stronger than  $\text{F}-\text{F}$  bond. The fluorine atoms are so small that electron-electron repulsions between the lone pairs decreases the strength of the bond.

**14.95**  $\text{HIO} < \text{HBrO} < \text{HClO} < \text{HClO}_2$  **14.99**  $\text{I}_2 < \text{Br}_2 < \text{Cl}_2$ , because  $\text{Cl}_2$  is able to oxidize Re to the  $+6$  oxidation state,  $\text{Br}_2$  only to the  $+5$  state, and  $\text{I}_2$  only to the  $+4$  state **14.100** helium; argon **14.102** Only dispersion forces hold atoms of the noble gases together. **14.106**  $\Delta H_{\text{soln}} = -411$  kJ **14.110**(a) Second ionization energies for alkali metals are so high because the electron being removed is from the next lower energy level and these are very tightly held by the nucleus. Also, the alkali metal would lose its noble gas electron configuration.

**14.112**(a) hyponitrous acid,  $\text{H}_2\text{N}_2\text{O}_2$ ; nitroxyl, HNO

(c) In both species the shape is bent about the N atoms.

**14.116** 13 t **14.118** In a disproportionation reaction, a substance acts as both a reducing agent and an oxidizing agent because atoms of an element within the substance attain both higher and lower oxidation states in the products. The disproportionation reactions are b, c, d, e, and f. **14.120**(a) Group 5A(15) (b) Group 7A(17) (c) Group 6A(16) (d) Group 1A(1) (e) Group 3A(13) (f) Group 8A(18) **14.122** 117.2 kJ

The nitronium ion ( $\text{NO}_2^+$ ) has a linear shape because the central N atom has two surrounding electron groups, which achieve minimum repulsion at  $180^\circ$ . The nitrite ion ( $\text{NO}_2^-$ ) bond angle is

more compressed than the nitrogen dioxide (NO<sub>2</sub>) bond angle because the lone pair of electrons takes up more space than the lone electron. **14.129**  $2.29 \times 10^4$  g UF<sub>6</sub> **14.133** O<sup>+</sup>, O<sup>-</sup>, and O<sup>2+</sup>  
**14.134**(a) 39.96 mass % in CuHAsO<sub>3</sub>; As, 62.42 mass % in (CH<sub>3</sub>)<sub>3</sub>As (b) 0.35 g CuHAsO<sub>3</sub>

## Chapter 15

**Answers to Boxed Reading Problems: B15.1** butane, 2 peaks;

2-methylpropane, 2 peaks; pentane, 3 peaks; 2-methylbutane, 4 peaks; 2,2-dimethylpropane, 1 peak **B15.2** 0.08 J/mol

• **15.2**(a) Carbon's electronegativity is midway between the most metallic and most nonmetallic elements of Period 2. To attain a filled outer shell, carbon forms covalent bonds to other atoms in molecules, network covalent solids, and polyatomic ions. (b) Since carbon has four valence shell electrons, it forms four covalent bonds to attain an octet. (c) To reach the He electron configuration, a carbon atom must lose four electrons, requiring too much energy to form the C<sup>4+</sup> cation. To reach the Ne electron configuration, the carbon atom must gain four electrons, also requiring too much energy to form the C<sup>4-</sup> anion. (d) Carbon is able to bond to itself extensively because its small size allows for close approach and great orbital overlap. The extensive orbital overlap results in a strong, stable bond. (e) The C—C σ bond is short enough to allow sideways overlap of unhybridized *p* orbitals of neighboring C atoms. The sideways overlap of *p* orbitals results in the π bonds that are part of double and triple bonds.

**15.3**(a) H, O, N, P, S, and halogens (b) Heteroatoms are atoms of any element other than carbon and hydrogen. (c) More electronegative than C: N, O, F, Cl, and Br; less electronegative than C: H and P. Sulfur and iodine have the same electronegativity as carbon. (d) Since carbon can bond to a wide variety of heteroatoms and to other carbon atoms, it can form many different compounds.

**15.6** The C—H and C—C bonds are unreactive because electronegativities are close and the bonds are short. The C—I bond is somewhat reactive because it is long and weak. The C=O bond is reactive because oxygen is more electronegative than carbon and the partially positive C atom attracts electron-rich atoms. The C—Li bond is also reactive because the bond polarity results in an electron-rich region around carbon and an electron-poor region around lithium. **15.7**(a) An alkane and a cycloalkane are organic compounds that consist of carbon and hydrogen and have only single bonds. A cycloalkane has a ring of carbon atoms. An alkene is a hydrocarbon with at least one double bond. An alkyne is a hydrocarbon with at least one triple bond. (b) alkane = C<sub>n</sub>H<sub>2n+2</sub>, cycloalkane = C<sub>n</sub>H<sub>2n</sub>, alkene = C<sub>n</sub>H<sub>2n</sub>, alkyne = C<sub>n</sub>H<sub>2n-2</sub> (c) Alkanes and cycloalkanes are saturated hydrocarbons. **15.10** a, c, and f

### 15.15(a)

15.17(a)  (b)  $\text{H}_2\text{C}=\text{CH}-\text{CH}_2-\text{CH}_3$

(c)  $\text{HC}\equiv\text{C}-\text{CH}-\text{CH}_3$  (d) Structure is correct.

15.19(a) 

(c) 3,4-dimethylheptane (d) 2,2-dimethylbutane

15.21(a)  $\text{CH}_3-\text{CH}_2-\text{CH}_2-\overset{\text{CH}_3}{\text{CH}}-\text{CH}_2-\text{CH}_3$   
Correct name is 3-methylhexane.

(b)  $\text{CH}_3-\text{CH}_2-\text{CH}_2-\overset{\text{CH}_2-\text{CH}_3}{\text{CH}}-\text{CH}_3$   
Correct name is 3-methylhexane.

Correct name is methylcyclohexane.

(d)  $\text{CH}_3-\text{CH}_2-\overset{\text{CH}_3}{\underset{\text{CH}_3}{\text{C}}}-\overset{\text{CH}_2-\text{CH}_3}{\text{CH}}-\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{CH}_3$

Correct name is 4-ethyl-3,3-dimethyloctane.

15.25(a) 3-Bromohexane is optically active.

(b) 3-Chloro-3-methylpentane is not optically active.

(c) 1,2-Dibromo-2-methylbutane is optically active.

*cis*-2-pentene

*trans*-2-pentene

*cis*-1-cyclohexylpropene

*trans*-1-cyclohexylpropene

(c) no geometric isomers

15.29(a) no geometric isomers

*cis*-3-hexene

*trans*-3-hexene

(c) no geometric isomers

*cis*-1,2-dichloroethene

*trans*-1,2-dichloroethene

15.31

1,2-dichlorobenzene  
(*o*-dichlorobenzene)

1,3-dichlorobenzene  
(*m*-dichlorobenzene)

1,4-dichlorobenzene  
(*p*-dichlorobenzene)

15.33

15.34

*cis*-2-methyl-3-hexene

*trans*-2-methyl-3-hexene

The compound 2-methyl-2-hexene does not have *cis-trans* isomers.

15.38  $\pi$  bond 15.40(a) elimination (b) addition

15.42(a)  $\text{CH}_3\text{CH}_2\text{CH}=\text{CHCH}_2\text{CH}_3 + \text{H}_2\text{O} \xrightarrow{\text{H}^+}$

(b)  $\text{CH}_3\text{CHBrCH}_3 + \text{CH}_3\text{CH}_2\text{OK} \longrightarrow$

(c)  $\text{CH}_3\text{CH}_3 + 2\text{Cl}_2 \xrightarrow{h\nu} \text{CHCl}_2\text{CH}_3 + 2\text{HCl}$

15.44(a) oxidation (b) reduction (c) reduction 15.46(a) oxidized

(b) oxidized 15.49(a) Methyl ethylamine is more soluble

because it has the ability to form H bonds with water molecules.

(b) 1-Butanol has a higher melting point because it can form intermolecular H bonds. (c) Propylamine has a higher boiling point because it contains N—H bonds that allow H bonding, and trimethylamine cannot form H bonds.

**15.52** Both groups react by addition to the  $\pi$  bond. The very polar  $C=O$  bond attracts the electron-rich O of water to the partially positive C. There is no such polarity in the alkene, so either C atom can be attacked, and two products result.

**15.55** Esters and acid anhydrides form through dehydration-condensation reactions, and water is the other product.

**15.57**(a) alkyl halide (b) nitrile (c) carboxylic acid (d) aldehyde

**15.73**(a) propanoic acid (b) ethylamine **15.77** addition reactions and condensation reactions **15.80** Dispersion forces are responsible for strong attractions between the long, unbranched chains of high-density polyethylene (HDPE). Low-density polyethylene (LDPE) has branching in the chains that prevents packing and weakens these attractions. **15.82** An amine and a carboxylic acid react to form a nylon; a carboxylic acid and an alcohol form a polyester.

**15.87**(a) condensation (b) addition (c) condensation (d) condensation

**15.89** The amino acid sequence in a protein determines its shape and structure, which determine its function. **15.92** The DNA base sequence determines the RNA base sequence, which determines the protein amino acid sequence.

**15.97**(a) AATCGG (b) TCTGTA **15.99** ACAATGCCT; this sequence codes for three amino acids. **15.101**(a) Both R groups are from cysteine, which can form a disulfide bond (covalent bond). (b) Lysine and aspartic acid give a salt link. (c) Asparagine and serine will hydrogen bond. (d) Valine and phenylalanine interact through dispersion forces. **15.106**(a) Perform an acid-catalyzed dehydration of the alcohol followed by addition of Br<sub>2</sub>. (b) Oxidize 1 mol of ethanol to acetic acid, then react 1 mol of acetic acid with 1 mol of ethanol to form the ester.

**15.108**

**15.109** (a)

(b) Carbon 1 is *sp*<sup>2</sup> hybridized. Carbon 2 is *sp*<sup>3</sup> hybridized.  
 Carbon 3 is *sp*<sup>3</sup> hybridized. Carbon 4 is *sp*<sup>2</sup> hybridized.  
 Carbon 5 is *sp*<sup>3</sup> hybridized. Carbons 6 and 7 are *sp*<sup>3</sup> hybridized.

(c) Carbons 2, 3, and 5 are chiral centers, as they are each bonded to four different groups. **15.113** The resonance structures show that the bond between carbon and nitrogen will have some double bond character that restricts rotation around the bond.

**15.116**(a) Hydrolysis requires the addition of water to break the peptide bonds. (b) glycine, 4; alanine, 1; valine, 3; proline, 6; serine, 7; arginine, 49 (c) 10,700 g/mol **15.117** When 2-butanone is reduced, equal amounts of both isomers are produced because the reaction does not favor the production of one over the other. The mixture is not optically active since the rotation of light to the right by one isomer cancels the rotation of light to the left by the other isomer.

**Chapter 16**

**Answers to Boxed Reading Problems:**

(b) rate =  $3 \times 10^7$  molecule/s

**B16.3** (a) Step 1 with Cl will have the higher value for the *p* factor. Since Cl is a single atom, no matter how it collides with the ozone molecule, the two particles should react, if the collision has enough energy. NO is a molecule. If the O<sub>3</sub> molecule collides with the N atom in the NO molecule, reaction can occur as a bond can form between N and O; if the O<sub>3</sub> molecule collides with the O atom in the NO molecule, reaction will not occur as the bond between N and O cannot form. The probability of a successful collision is smaller with NO. (b)  $\text{:}\ddot{\text{C}}\text{:} \cdots \cdots \ddot{\text{O}} \cdots \cdots \text{O}=\ddot{\text{O}}$

• **16.2** Reaction rate is proportional to concentration. An increase in pressure will increase the concentration of gas-phase reactants, resulting in an increased rate. **16.3** The addition of water will lower the concentrations of all dissolved solutes, and the rate will decrease. **16.5** An increase in temperature increases the rate by increasing the number of collisions between particles, but more importantly, it increases the energy of collisions. **16.8**(a) The instantaneous rate is the rate at one point in time during the reaction. The average rate is the average over a period of time. On a graph of reactant concentration vs. time, the instantaneous rate is the slope of the tangent to the curve at any point. The average rate is the slope of the line connecting two points on the curve. The closer together the two points (the shorter the time interval), the closer the average rate is to the instantaneous rate. (b) The initial rate is the instantaneous rate at the point on the graph where *t* = 0, that is, when reactants are mixed.

**16.10**

**16.12**(a) rate =  $-\left(\frac{1}{2}\right) \frac{\Delta[\text{AX}_2]}{\Delta t}$   
 $= -\left(\frac{1}{2}\right) \frac{(0.0088 \text{ mol/L} - 0.0500 \text{ mol/L})}{(20.0 \text{ s} - 0 \text{ s})}$   
 $= 0.0010 \text{ mol/L}\cdot\text{s}$

Estimated initial rate = 0.004 mol/L·s. The initial rate is higher than the average rate because the rate decreases as reactant concentration decreases.

$$16.14 \text{ rate} = -\frac{1}{2} \frac{\Delta[A]}{\Delta t} = \frac{\Delta[B]}{\Delta t} = \frac{\Delta[C]}{\Delta t}; 4 \text{ mol/L}\cdot\text{s}$$

$$16.16 \text{ rate} = -\frac{\Delta[A]}{\Delta t} = -\frac{1}{2} \frac{\Delta[B]}{\Delta t} = \frac{\Delta[C]}{\Delta t}; 0.2 \text{ mol/L}\cdot\text{s}$$

$$16.21 \text{ rate} = -\frac{\Delta[\text{N}_2]}{\Delta t} = -\frac{1}{3} \frac{\Delta[\text{H}_2]}{\Delta t} = \frac{1}{2} \frac{\Delta[\text{NH}_3]}{\Delta t}$$

$$16.22(\text{a}) \text{ rate} = -\frac{1}{3} \frac{\Delta[\text{O}_2]}{\Delta t} = \frac{1}{2} \frac{[\Delta\text{O}_3]}{\Delta t}$$

$$(\text{b}) 1.45 \times 10^{-5} \text{ mol/L}\cdot\text{s}$$

**16.23(a)**  $k$  is the rate constant, the proportionality constant in the rate law; it is specific to the reaction and that temperature at which the reaction occurs. (b)  $m$  represents the order of the reaction with respect to  $[A]$ , and  $n$  represents the order of the reaction with respect to  $[B]$ . The order of a reactant does not necessarily equal its stoichiometric coefficient in the balanced equation. (c)  $\text{L}^2/\text{mol}^2\cdot\text{min}$  **16.25(a)** Rate doubles. (b) Rate decreases by a factor of 4. (c) Rate increases by a factor of 9.

**16.26** first order in  $\text{BrO}_3^-$ ; first order in  $\text{Br}^-$ ; second order in  $\text{H}^+$ ; fourth order overall **16.28(a)** Rate doubles. (b) Rate is halved. (c) The rate increases by a factor of 16. **16.30** second order in  $\text{NO}_2$ ; first order in  $\text{Cl}_2$ ; third order overall **16.32(a)** Rate increases by a factor of 9. (b) Rate increases by a factor of 8. (c) Rate is halved.

**16.34(a)** second order in A; first order in B (b)  $\text{rate} = k[A]^2[B]$  (c)  $5.00 \times 10^3 \text{ L}^2/\text{mol}^2\cdot\text{min}$  **16.36(a)**  $\text{time}^{-1}$  (b)  $\text{L}/\text{mol}\cdot\text{time}$  (c)  $\text{L}^2/\text{mol}^2\cdot\text{time}$  (d)  $\text{L}^{3/2}/\text{mol}^{3/2}\cdot\text{time}$  **16.39** The integrated rate law can be used to plot a graph. If the plot of  $[\text{reactant}]$  versus time is linear, the order is zero. If the plot of  $\ln[\text{reactant}]$  versus time is linear, the order is first. If the plot of inverse concentration ( $1/[\text{reactant}]$ ) versus time is linear, the order is second. (a) first order (b) second order (c) zero order **16.41** 7 s **16.43** 22 minutes **16.45(a)**  $k = 0.0660 \text{ min}^{-1}$  (b) 21.0 min

16.47(a)	x-axis (time, s)	$[\text{NH}_3]$	y-axis ( $\ln [\text{NH}_3]$ )
	0	4.000 M	1.38629
	1.000	3.986 M	1.38279
	2.000	3.974 M	1.37977

$$k = 3 \times 10^{-3} \text{ s}^{-1}$$

$$(\text{b}) t_{1/2} = 2 \times 10^2 \text{ s}$$

**16.49** No, other factors that affect the rate are the energy and orientation of the collisions. **16.52** Measure the rate constant at a series of temperatures and plot  $\ln k$  versus  $1/T$ . The slope of the line equals  $-E_a/R$ . **16.55** No, reaction is reversible and will

eventually reach a state where the forward and reverse rates are equal. When this occurs, there are no concentrations equal to zero. Since some reactants are reformed from EF, the amount of EF will be less than  $4 \times 10^{-5} \text{ mol}$ . **16.56** At the same temperature, both reaction mixtures have the same average kinetic energy, but the reactant molecules do not have the same average velocity.

The trimethylamine molecule has greater mass than the ammonia molecule, so trimethylamine molecules will collide less often with HCl molecules. Moreover, the bulky groups bonded to nitrogen in trimethylamine mean that collisions with HCl having the correct orientation occur less frequently. Therefore, the rate of the reaction between  $\text{NH}_3$  and HCl is higher. **16.57** 12 unique collisions **16.59**  $2.96 \times 10^{-18}$  **16.61**  $0.033 \text{ s}^{-1}$

$$(\text{b}) 2.70 \times 10^2 \text{ kJ/mol}$$

**16.66(a)** Because the enthalpy change is positive, the reaction is endothermic.

**16.67** The rate of an overall reaction depends on the rate of the slowest step. The rate of the overall reaction will be lower than the average of the individual rates because the average includes higher rates as well. **16.71** The probability of three particles colliding with one another with the proper energy and orientation is much less than the probability of two particles doing so.

**16.72** No, the overall rate law must contain only reactants (no intermediates), and the overall rate is determined by the slow step.

(b) X and Y are intermediates.

(c) Step	Molecularity	Rate Law
$A(g) + B(g) \rightleftharpoons X(g)$	bimolecular	$\text{rate}_1 = k_1[A][B]$
$X(g) + C(g) \longrightarrow Y(g)$	bimolecular	$\text{rate}_2 = k_2[X][C]$
$Y(g) \longrightarrow D(g)$	unimolecular	$\text{rate}_3 = k_3[Y]$

(d) yes (e) yes **16.76** The proposed mechanism is valid because the individual steps are chemically reasonable, they add to give the overall equation, and the rate law for the mechanism matches the observed rate law. **16.79** No. A catalyst changes the mechanism of a reaction to one with lower activation energy. Lower activation energy means a faster reaction. An increase in temperature does not influence the activation energy, but increases the fraction of collisions with sufficient energy to equal or exceed the activation energy. **16.80**(a) No. The spark provides energy that is absorbed by the  $H_2$  and  $O_2$  molecules to achieve the activation energy. (b) Yes. The powdered metal acts as a heterogeneous catalyst, providing a surface on which the oxygen-hydrogen reaction can proceed with a lower activation energy.

**16.85**(a) Water does not appear as a reactant in the rate-determining step.  
 (b) Step 1:  $\text{rate}_1 = k_1[(CH_3)_3CBr]$   
 Step 2:  $\text{rate}_2 = k_2[(CH_3)_3C^+]$   
 Step 3:  $\text{rate}_3 = k_3[(CH_3)_3COH_2^+]$   
 (c)  $(CH_3)_3C^+$  and  $(CH_3)_3COH_2^+$   
 (d) The rate-determining step is step 1. The rate law for this step agrees with the rate law observed with  $k = k_1$ .

**16.87**  $4.61 \times 10^4 \text{ J/mol}$  **16.91**(a) Rate increases 2.5 times. (b) Rate is halved. (c) Rate decreases by a factor of 0.01. (d) Rate does not change. **16.92** second order **16.95** 57 yr **16.98**(a)  $0.21 \text{ h}^{-1}$ ; 3.3 h (b) 6.6 h (c) If the concentration of sucrose is relatively low, the concentration of water remains nearly constant even with small changes in the amount of water. This gives an apparent zero-order reaction with respect to water. Thus, the reaction is first order overall because the rate does not change with changes in the amount of water. **16.101**(a)  $0.68 \text{ M}$  (b) 0.57 **16.104** 71 kPa **16.108**  $7.3 \times 10^3 \text{ J/mol}$  **16.110**(a)  $2.4 \times 10^{-15} \text{ M}$  (b)  $2.4 \times 10^{-11} \text{ mol/L}\cdot\text{s}$  **16.113**(a) 2.8 days (b) 7.4 days (c)  $4.5 \text{ mol/m}^3$  **16.116**(a)  $\text{rate}_1 = 1.7 \times 10^{-5} \text{ M s}^{-1}$ ;  $\text{rate}_2 = 3.4 \times 10^{-5} \text{ M s}^{-1}$ ;  $\text{rate}_3 = 3.4 \times 10^{-5} \text{ M s}^{-1}$  (b) zero order with respect to  $S_2O_8^{2-}$ ; first order with respect to  $I^-$  (c)  $4.3 \times 10^{-4} \text{ s}^{-1}$  (d)  $\text{rate} = (4.3 \times 10^{-4} \text{ s}^{-1})[KI]$  **16.118**(a)  $7 \times 10^4 \text{ cells/L}$  (b) 20. min **16.121**(a) Use the Monod equation.

### Chapter 17

**Answers to Boxed Reading Problems: B17.1**(a) Enzyme 3 (b) Enzyme 6 (c) If F inhibited enzyme 1, neither branch of the pathway would occur when enough F was made and product I would be lacking. (d) If F inhibited enzyme 6, the second branch would not take place when enough F was made, and more F would build up.

• **17.1** If the change is in concentration, it results temporarily in more products and less reactants. After equilibrium is re-established,  $K_c$  remains unchanged because the ratio of products and reactants remains the same. **17.7** The equilibrium constant expression is  $K = [\text{O}_2]$ . If the temperature remains constant,  $K$  remains constant. If the initial amount of  $\text{Li}_2\text{O}_2$  present is sufficient to reach equilibrium, the amount of  $\text{O}_2$  obtained will be constant.

**17.8**(a)  $Q = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]}$

The value of  $Q$  increases as a function of time until it reaches the value of  $K$ . (b) no **17.11** Yes. If  $Q_1$  is for the formation of 1 mol  $\text{NH}_3$  from  $\text{H}_2$  and  $\text{N}_2$ , and  $Q_2$  is for the formation of  $\text{NH}_3$  from  $\text{H}_2$  and 1 mol of  $\text{N}_2$ , then  $Q_2 = Q_1^2$ .

17.52  $[\text{HI}] = 0.0152$  M;  $[\text{I}_2] = 0.00328$  M

17.54  $[\text{I}_2]_{\text{eq}} = [\text{Cl}_2]_{\text{eq}} = 0.0199$  M;  $[\text{ICl}]_{\text{eq}} = 0.0601$  M

17.56  $6.01 \times 10^{-6}$  17.59 Equilibrium position refers to the specific concentrations or pressures of reactants and products that exist at equilibrium, whereas equilibrium constant is the overall ratio of equilibrium concentrations or pressures. Equilibrium position changes as a result of a change in reactant (or product) concentration.

17.60(a) B, because the amount of product increases with temperature (b) A, because the lowest temperature will give the least product 17.64(a) shifts toward products (b) shifts toward

products (c) does not shift (d) shifts toward reactants

17.66(a) more F and less  $\text{F}_2$  (b) more  $\text{C}_2\text{H}_2$  and  $\text{H}_2$  and less  $\text{CH}_4$

17.68(a) no effect (b) less  $\text{H}_2$  and  $\text{O}_2$  and more  $\text{H}_2\text{O}$  17.70(a) no change (b) increase volume 17.72(a) amount decreases

(b) amounts increase (c) amounts increase (d) amount decreases 17.74 2.0 17.77(a) lower temperature, higher pressure (b)  $Q$  decreases; no change in  $K$  (c) Reaction rates are lower at lower temperatures, so a catalyst is used to speed up the reaction.

17.79(a)  $P_{\text{N}_2} = 31$  atm;  $P_{\text{H}_2} = 93$  atm;  $P_{\text{total}} = 174$  atm

(b)  $P_{\text{N}_2} = 18$  atm;  $P_{\text{H}_2} = 111$  atm;  $P_{\text{total}} = 179$  atm; not a valid suggestion 17.82 0.204 atm 17.85(a)  $3 \times 10^{-3}$  atm (b) high

pressure; low temperature (c)  $2 \times 10^5$  (d) No, because water condenses at a higher temperature. 17.87(a) 0.016 atm

(b)  $K_c = 5.6 \times 10^2$ ;  $P_{\text{SO}_2} = 0.16$  atm 17.89 12.5 g  $\text{CaCO}_3$

17.93 Both concentrations increased by a factor of 2.2.

17.95(a)  $3.0 \times 10^{-14}$  atm (b) 0.013 pg  $\text{CO/L}$

17.97(a) 98.0% (b) 99.0% (c)  $2.60 \times 10^5$  J/mol

17.99(a)  $2\text{CH}_4(g) + \text{O}_2(g) + 2\text{H}_2\text{O}(g) \rightleftharpoons 2\text{CO}_2(g) + 6\text{H}_2(g)$

(b)  $1.76 \times 10^{29}$  (c)  $3.19 \times 10^{23}$  (d) 48 atm 17.100(a)  $4.0 \times 10^{-21}$  atm

(b)  $5.5 \times 10^{-8}$  atm (c) 29 N atoms/L;  $4.0 \times 10^{14}$  H atoms/L

(d) The more reasonable step is  $\text{N}_2(g) + \text{H}(g) \rightarrow \text{NH}(g) + \text{N}(g)$ . With only 29 N atoms in 1.0 L, the first reaction would produce virtually no  $\text{NH}(g)$  molecules. There are orders of magnitude more  $\text{N}_2$  molecules than N atoms, so the second reaction is the more reasonable step. 17.103(a)  $P_{\text{N}_2} = 0.780$  atm;  $P_{\text{O}_2} = 0.210$  atm;  $P_{\text{NO}} = 2.67 \times 10^{-16}$  atm (b) 0.990 atm (c)  $K_c = K_p = 4.35 \times 10^{-31}$  17.105(a)  $1.26 \times 10^{-3}$  (b) 794 (c)  $-51.8$  kJ (d)  $1.2 \times 10^4$  J/mol 17.109(a) 1.52 (b) 0.9626 atm (c) 0.2000 mol  $\text{CO}$  (d) 0.01097 M

## Chapter 18

18.2 All Arrhenius acids have H in their formula and produce hydronium ion ( $\text{H}_3\text{O}^+$ ) in aqueous solution. All Arrhenius bases have OH in their formula and produce hydroxide ion ( $\text{OH}^-$ ) in aqueous solution. Neutralization occurs when each  $\text{H}_3\text{O}^+$  ion combines with an  $\text{OH}^-$  ion to form two molecules of  $\text{H}_2\text{O}$ . Chemists found the reaction of any strong base with any strong acid always had  $\Delta H = -56$  kJ/mol  $\text{H}_2\text{O}$  produced. 18.4 Strong acids and bases dissociate completely into ions when dissolved in water. Weak acids and bases dissociate only partially. The characteristic property of all weak acids is that a great majority of the acid molecules are undissociated in aqueous solution.

18.5 a, c, and d 18.7 b and d

18.9(a)  $K_a = \frac{[\text{CN}^-][\text{H}_3\text{O}^+]}{[\text{HCN}]}$

(b)  $K_a = \frac{[\text{CO}_3^{2-}][\text{H}_3\text{O}^+]}{[\text{HCO}_3^-]}$

(c)  $K_a = \frac{[\text{HCOO}^-][\text{H}_3\text{O}^+]}{[\text{HCOOH}]}$

18.11(a)  $K_a = \frac{[\text{NO}_2^-][\text{H}_3\text{O}^+]}{[\text{HNO}_2]}$

(b)  $K_a = \frac{[\text{CH}_3\text{COO}^-][\text{H}_3\text{O}^+]}{[\text{CH}_3\text{COOH}]}$

18.17(a) strong base (b) strong acid (c) weak acid (d) weak acid

18.22(a) The acid with the smaller  $K_a$  ( $4 \times 10^{-5}$ ) has the higher pH, because less dissociation yields fewer hydronium ions.

(b) The acid with the larger  $pK_a$  (3.5) has the higher pH, because it has a smaller  $K_a$  and, thus, lower  $[H_3O^+]$ . (c) The solution of lower concentration (0.01 M) contains fewer hydronium ions.

(d) A 0.1 M weak acid solution contains fewer hydronium ions.

(e) The 0.01 M base solution contains more hydroxide ions, so fewer hydronium ions. (f) The solution that has  $pOH = 6.0$  has the higher pH:  $pH = 14.0 - 6.0 = 8.0$ .

18.23(a) 12.05; basic

(b) 11.13; acidic 18.25(a) 2.212; acidic (b) -0.708; basic

18.27(a)  $[H_3O^+] = 1.4 \times 10^{-10} M$ ,  $[OH^-] = 7.1 \times 10^{-5} M$ ,  $pOH = 4.15$

(b)  $[H_3O^+] = 2.7 \times 10^{-5} M$ ,  $[OH^-] = 3.7 \times 10^{-10} M$ ,  $pH = 4.57$

18.29(a)  $[H_3O^+] = 1.7 \times 10^{-5} M$ ,  $[OH^-] = 5.9 \times 10^{-10} M$ ,  $pOH = 9.23$

18.36(a)  $2H_2O(l) + \text{heat} \rightleftharpoons H_3O^+(aq) + OH^-(aq)$ . As the temperature increases, the reaction shifts to the formation of products; rising temperature increases the value of  $K_w$ .

(b)  $K_w = 2.5 \times 10^{-14}$ ;  $pOH = 6.80$ ;  $[OH^-] = 1.6 \times 10^{-7} M$

18.37 The Brønsted-Lowry model defines acids as proton donors and bases as proton acceptors, while the Arrhenius model defines acids as species containing ionizable hydrogen atoms and bases as species containing hydroxide ions. In both definitions, an acid produces  $H_3O^+$  ions and a base produces  $OH^-$  ions when added to water. Ammonia and carbonate ion are two Brønsted-Lowry bases that are not Arrhenius bases because they do not contain  $OH^-$  ions. Brønsted-Lowry acids must contain an ionizable hydrogen atom in order to be proton donors, so a Brønsted-Lowry acid is also an Arrhenius acid. 18.40 An amphiprotic species is one that can lose a proton to act as an acid or gain a proton to act as a base. The dihydrogen phosphate ion,  $H_2PO_4^-$ , is an example.

(b) In an oxygen-deficient environment, the equilibrium shifts to the left to release oxygen. (c) A decrease in  $[\text{H}_3\text{O}^+]$  shifts the equilibrium to the right. More oxygen is absorbed, but it will be more difficult to remove the  $\text{O}_2$ .  
 (d) An increase in  $[\text{H}_3\text{O}^+]$  shifts the equilibrium to the left. Less oxygen is bound to Hb, but it will be easier to remove it. **18.183**(a) 1.012 M (b) 0.004 M (c) 0.4% **18.184**(a) 10.0 (b) The  $\text{p}K_b$  for the N in the  $3^\circ$  amine group is much smaller than that for the N in the aromatic ring; thus, the  $K_b$  for the former is significantly larger (yielding a much greater amount of  $\text{OH}^-$ ). (c) 4.7 (d) 5.1

## Chapter 19

**Answers to Boxed Reading Problems: B19.2**(a) 65 mol (b) 6.28 (c)  $4.0 \times 10^3 \text{ g HCO}_3^-$

- **19.2** The acid component neutralizes added base, and the base component neutralizes added acid, so the pH of the buffer solution remains relatively constant. The components of a buffer do not neutralize one another because they are a conjugate acid-base pair. **19.6** The buffer range, the pH range over which the buffer acts effectively, is consistent with a buffer-component concentration ratio from 10 to 0.1. This gives a pH range equal to  $\text{p}K_a \pm 1$ . **19.8**(a) Ratio and pH increase; added  $\text{OH}^-$  reacts with HA. (b) Ratio and pH decrease; added  $\text{H}^+$  reacts with  $\text{A}^-$ . (c) Ratio and pH increase; added  $\text{A}^-$  increases  $[\text{A}^-]$ . (d) Ratio and pH decrease; added HA increases  $[\text{HA}]$ . **19.10**(a) buffer 3 (b) All of the buffers have the same pH range. (c) buffer 2 **19.12**  $[\text{H}_3\text{O}^+] = 5.6 \times 10^{-6} M$ ; pH = 5.25 **19.14**  $[\text{H}_3\text{O}^+] = 5.2 \times 10^{-4} M$ ; pH = 3.28 **19.16** 3.89 **19.18** 10.03 **19.20** 9.47 **19.22**(a)  $K_{a2}$  (b) 10.55 **19.24** 3.6 **19.26** 0.20 **19.28** 3.37 **19.30** 8.82 **19.32**(a) 4.81 (b) 0.66 g KOH **19.34**(a)  $\text{HOOC}(\text{CH}_2)_4\text{COOH}/\text{HOOC}(\text{CH}_2)_4\text{COO}^-$  or  $\text{C}_6\text{H}_5\text{NH}_3^+/\text{C}_6\text{H}_5\text{NH}_2$  (b)  $\text{H}_2\text{PO}_4^-/\text{HPO}_4^{2-}$

or  $\text{H}_2\text{AsO}_4^-/\text{HAsO}_4^{2-}$  **19.36**(a)  $\text{HOCH}_2\text{CH}(\text{OH})\text{COOH}/\text{HOCH}_2\text{CH}(\text{OH})\text{COO}^-$  or  $\text{CH}_3\text{COOC}_6\text{H}_4\text{COOH}/\text{CH}_3\text{COOC}_6\text{H}_4\text{COO}^-$  (b)  $\text{C}_5\text{H}_5\text{NH}^+/\text{C}_5\text{H}_5\text{N}$  **19.39** 1.6  
**19.41**(a) initial pH: *strong acid*–*strong base* < *weak acid*–*strong base* < *weak base*–*strong acid* (b) pH at equivalence point: *weak base*–*strong acid* < *strong acid*–*strong base* < *weak acid*–*strong base* **19.43** At the midpoint of the buffer region, the concentrations of weak acid and conjugate base are equal, so the  $\text{pH} = \text{p}K_a$  of the acid. **19.45** To see a distinct color in a mixture of two colors, you need one color to have about 10 times the intensity of the other. For this to be the case, the concentration ratio  $[\text{HIn}]/[\text{In}^-]$  has to be greater than 10/1 or less than 1/10. This occurs when  $\text{pH} = \text{p}K_a - 1$  or  $\text{pH} = \text{p}K_a + 1$ , respectively, giving a pH range of about 2 units. **19.47** The equivalence point in a titration is the point at which the number of moles of base is stoichiometrically equivalent to the number of moles of acid. The end point is the point at which the indicator changes color. If an appropriate indicator is selected, the end point is close to the equivalence point, but they are not usually the same. The pH at the end point, or at the color change, may precede or follow the pH at the equivalence point, depending on the indicator chosen. **19.49**(a) 1.0000 (b) 1.6368 (c) 2.898 (d) 3.903 (e) 7.00 (f) 10.10 (g) 12.05 **19.51**(a) 2.91 (b) 4.81 (c) 5.29 (d) 6.09 (e) 7.41 (f) 8.76 (g) 10.10 (h) 12.05 **19.53**(a) 8.54 and 59.0 mL (b) 4.39 and 66.0 mL, 9.68 and total 132.1 mL **19.55**(a) 5.17 and 123 mL (b) 5.80 and 194 mL **19.57** pH range from 7.5 to 9.5 **19.59**(a) bromthymol blue (b) thymol blue or phenolphthalein **19.61**(a) methyl red (b) bromthymol blue **19.64** Fluoride ion is the conjugate base of a weak acid and reacts with  $\text{H}_2\text{O}$ :  $\text{F}^-(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{HF}(aq) + \text{OH}^-(aq)$ . As the pH increases, the equilibrium shifts to the left and  $[\text{F}^-]$  increases. As the pH decreases, the equilibrium shifts to the right and  $[\text{F}^-]$  decreases. The changes in  $[\text{F}^-]$  influence the solubility of  $\text{BaF}_2$ . Chloride ion is the conjugate base of a strong acid, so it does not react with water and its concentration is not influenced by pH. **19.66** The ionic compound precipitates. **19.67**(a)  $K_{sp} = [\text{Ag}^+]^2[\text{CO}_3^{2-}]$  (b)  $K_{sp} = [\text{Ba}^{2+}][\text{F}^-]^2$  (c)  $K_{sp} = [\text{Cu}^{2+}][\text{S}^{2-}]$  **19.69**(a)  $K_{sp} = [\text{Ca}^{2+}][\text{CrO}_4^{2-}]$  (b)  $K_{sp} = [\text{Ag}^+][\text{CN}^-]$  (c)  $K_{sp} = [\text{Ag}^+]^3[\text{PO}_4^{3-}]$  **19.71**  $1.3 \times 10^{-4}$  **19.73**  $2.8 \times 10^{-11}$  **19.75**(a)  $2.3 \times 10^{-5} M$  (b)  $4.2 \times 10^{-9} M$  **19.77**(a)  $1.7 \times 10^{-3} M$  (b)  $2.0 \times 10^{-4} M$  **19.79**(a)  $\text{Mg}(\text{OH})_2$  (b)  $\text{PbS}$  (c)  $\text{Ag}_2\text{SO}_4$  **19.81**(a)  $\text{CaSO}_4$  (b)  $\text{Mg}_3(\text{PO}_4)_2$  (c)  $\text{PbSO}_4$  **19.83**(a)  $\text{AgCl}(s) \rightleftharpoons \text{Ag}^+(aq) + \text{Cl}^-(aq)$ . The chloride ion is the anion of a strong acid, so it does not react with  $\text{H}_3\text{O}^+$ . No change with pH. (b)  $\text{SrCO}_3(s) \rightleftharpoons \text{Sr}^{2+}(aq) + \text{CO}_3^{2-}(aq)$  The strontium ion is the cation of a strong base, so pH will not affect its solubility. The carbonate ion acts as a base:  $\text{CO}_3^{2-}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{HCO}_3^-(aq) + \text{OH}^-(aq)$  also  $\text{CO}_2(g)$  forms and escapes:  $\text{CO}_3^{2-}(aq) + 2\text{H}_3\text{O}^+(aq) \rightarrow \text{CO}_2(g) + 3\text{H}_2\text{O}(l)$ . Therefore, the solubility of  $\text{SrCO}_3$  will increase with addition of  $\text{H}_3\text{O}^+$  (decreasing pH). **19.85**(a)  $\text{Fe}(\text{OH})_2(s) \rightleftharpoons \text{Fe}^{2+}(aq) + 2\text{OH}^-(aq)$  The  $\text{OH}^-$  ion reacts with added  $\text{H}_3\text{O}^+$ :  $\text{OH}^-(aq) + \text{H}_3\text{O}^+(aq) \rightarrow 2\text{H}_2\text{O}(l)$ . The added  $\text{H}_3\text{O}^+$  consumes the  $\text{OH}^-$ , driving the equilibrium toward the right to dissolve more  $\text{Fe}(\text{OH})_2$ . Solubility increases with addition of  $\text{H}_3\text{O}^+$  (decreasing pH). (b)  $\text{CuS}(s) \rightleftharpoons \text{Cu}^{2+}(aq) + \text{S}^{2-}(aq)$   $\text{S}^{2-}$  is the anion of a weak acid, so it reacts with added  $\text{H}_3\text{O}^+$ . Solubility increases with

addition of  $\text{H}_3\text{O}^+$  (decreasing pH). **19.87** yes **19.89** yes **19.92**(a)  $\text{Fe}(\text{OH})_3$  (b) The two metal ions are separated by adding just enough  $\text{NaOH}$  to precipitate iron(III) hydroxide. (c)  $2.0 \times 10^{-7} M$  **19.95** No, because it indicates that a complex ion forms between the zinc ion and hydroxide ions, such as  $\text{Zn}^{2+}(aq) + 4\text{OH}^-(aq) \rightleftharpoons \text{Zn}(\text{OH})_4^{2-}(aq)$

**19.100**  $8.1 \times 10^{-15} M$  **19.102** 0.05 M **19.104**  $1.0 \times 10^{-16} M \text{Zn}^{2+}$ ;

## Chapter 20

**Answer to Problem: B20.2**  $-12.6$  kJ/mol

• **20.2** A spontaneous process occurs by itself, whereas a nonspontaneous process requires a continuous input of energy to make it happen. It is possible to cause a nonspontaneous process to occur, but the process stops once the energy input is removed. A reaction that is nonspontaneous under one set of conditions may be spontaneous under a different set of conditions.  
**20.5** The transition from liquid to gas involves a greater increase in dispersal of energy and freedom of motion than does the transition from solid to liquid. **20.6** For an exothermic reaction,  $\Delta S_{\text{surr}} > 0$ . For an endothermic reaction,  $\Delta S_{\text{surr}} < 0$ . A chemical cold pack for injuries is an example of an application using a spontaneous endothermic process. **20.8** a, b, and c  
**20.10** a and b **20.12**(a) positive (b) negative (c) negative  
**20.14**(a) positive (b) positive (c) positive  
**20.16**(a) negative (b) negative (c) positive  
**20.18**(a) positive (b) negative (c) positive  
**20.20**(a) positive (b) negative (c) positive  
**20.22**(a) Butane; the double bond in 2-butene restricts freedom of rotation. (b) Xe(g); it has the greater molar mass. (c) CH<sub>4</sub>(g); gases have greater entropy than liquids. **20.24**(a) C<sub>2</sub>H<sub>5</sub>OH(l); it is a more complex molecule. (b) KClO<sub>3</sub>(aq); ions in solution have their energy more dispersed than ions in a solid. (c) K(s); it has a greater molar mass. **20.26**(a) Diamond < graphite < charcoal. Freedom of motion is least in the network solid, increases for graphite sheets, and is greatest in the amorphous solid. (b) Ice < liquid water < water vapor. Entropy increases as a substance changes from solid to liquid to gas. (c) O atoms < O<sub>2</sub> < O<sub>3</sub>. Entropy increases with molecular complexity. **20.28**(a) ClO<sub>4</sub><sup>-</sup>(aq) > ClO<sub>3</sub><sup>-</sup>(aq) > ClO<sub>2</sub><sup>-</sup>(aq); decreasing molecular complexity (b) NO<sub>2</sub>(g) > NO(g) > N<sub>2</sub>(g). N<sub>2</sub> has lower standard molar entropy because it consists of two of the same atoms; the other species have two different types of atoms. NO<sub>2</sub> is more complex than NO. (c) Fe<sub>3</sub>O<sub>4</sub>(s) > Fe<sub>2</sub>O<sub>3</sub>(s) > Al<sub>2</sub>O<sub>3</sub>(s). Fe<sub>3</sub>O<sub>4</sub> is more complex and more massive. Fe<sub>2</sub>O<sub>3</sub> is more massive than Al<sub>2</sub>O<sub>3</sub>. **20.31** For a system at equilibrium,  $\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = 0$ . For a system moving to equilibrium,  $\Delta S_{\text{univ}} > 0$ . **20.32**  $S_{\text{Cl}_2\text{O}(g)}^\circ = 2S_{\text{HClO}(g)}^\circ - S_{\text{H}_2\text{O}(g)}^\circ - \Delta S_{\text{rxn}}^\circ$   
**20.33**(a) negative;  $\Delta S^\circ = -172.4$  J/K (b) positive;  $\Delta S^\circ = 141.6$  J/K (c) negative;  $\Delta S^\circ = -837$  J/K  
**20.35**  $\Delta S^\circ = 93.1$  J/K; yes, the positive sign of  $\Delta S$  is expected because there is a net increase in the number of gas molecules.  
**20.37**  $\Delta S^\circ = -311$  J/K; yes, the negative entropy change matches the decrease in moles of gas. **20.39**(a)  $-75.6$  J/K; (b) 490. J/K; because  $\Delta S_{\text{univ}}$  is positive, the reaction is spontaneous at 298 K. **20.41**(a)  $-242$  J/K (b) 559 J/K; because  $\Delta S_{\text{univ}}$  is positive, the reaction is spontaneous at 298 K. **20.44**  $-97.2$  J/K **20.46** A spontaneous process has  $\Delta S_{\text{univ}} > 0$ . Since the absolute temperature is always positive,  $\Delta G_{\text{sys}}$  must be negative ( $\Delta G_{\text{sys}} < 0$ ) for a spontaneous process.

**20.48**(a)  $\Delta H_{\text{sys}}$  is negative. Bonds are being formed, which is an exothermic process. (b)  $\Delta S_{\text{sys}}$  is negative. As molecules form from atoms, the total number of particles decreases and, with it, the entropy of the system. (c) Since  $\Delta H_{\text{sys}}$  is negative, heat is released, so  $\Delta S_{\text{surr}}$  will be positive. (d) Because both  $\Delta H_{\text{sys}}$  and  $\Delta S_{\text{sys}}$  are negative, this reaction will become more spontaneous ( $\Delta G_{\text{sys}}$  will become more negative) as temperature decreases. **20.49**  $\Delta H^\circ$  is positive and  $\Delta S^\circ$  is positive. Melting is an example. **20.50** The entropy changes little within a phase. As long as a substance does not change phase, the value of  $\Delta S^\circ$  is relatively unaffected by temperature. **20.51**(a)  $-1138.0$  kJ (b)  $-1379.4$  kJ (c)  $-224$  kJ **20.53**(a)  $-1138$  kJ (b)  $-1379$  kJ (c)  $-226$  kJ **20.55**(a) Entropy decreases ( $\Delta S^\circ$  is negative) because the number of moles of gas decreases. The combustion of CO releases energy ( $\Delta H^\circ$  is negative). (b)  $-257.2$  kJ (using Equation 20.8) or  $-257.3$  kJ (using Equation 20.7). **20.57**(a)  $-0.409$  kJ/mol·K (b)  $-197$  kJ/mol **20.59**(a)  $\Delta H_{\text{rxn}}^\circ = 90.7$  kJ;  $\Delta S_{\text{rxn}}^\circ = 221$  J/K (b) At 28°C,  $\Delta G^\circ = 24.3$  kJ; at 128°C,  $\Delta G^\circ = 2.2$  kJ; at 228°C,  $\Delta G^\circ = -19.9$  kJ (c) For the substances in their standard states, the reaction is nonspontaneous at 28°C, near equilibrium at 128°C, and spontaneous at 228°C. (d) 410. K **20.61**(a)  $\Delta H_{\text{rxn}}^\circ = -241.826$  kJ,  $\Delta S_{\text{rxn}}^\circ = -44.4$  J/K,  $\Delta G_{\text{rxn}}^\circ = -228.60$  kJ (b) Yes. The reaction will become nonspontaneous at higher temperatures. (c) The reaction is spontaneous below  $5.45 \times 10^3$  K. **20.63**(a)  $\Delta G^\circ$  is a relatively large positive value. (b)  $K \gg 1$ .  $Q$  depends on initial conditions, not equilibrium conditions. **20.66** The standard free energy change,  $\Delta G^\circ$ , applies when all components of the system are in their standard states;  $\Delta G^\circ = \Delta G$  when all concentrations equal 1 M and all partial pressures equal 1 atm. **20.67**(a)  $2.0 \times 10^{-8}$  (b)  $1.27 \times 10^{21}$  **20.69**(a)  $3.46 \times 10^4$  (b)  $8.2 \times 10^{-7}$  **20.71**  $\Delta H^\circ = 30910$  J,  $\Delta S^\circ = 93.15$  J/K,  $T = 331.8$  K **20.73**  $1.7 \times 10^{-49}$   
**20.75**  $3.36 \times 10^5$  **20.77**  $2.7 \times 10^4$  J/mol; no **20.79**(a)  $2.9 \times 10^4$  J/mol (b) The reverse direction, formation of reactants, is spontaneous, so the reaction proceeds to the left. (c)  $7.0 \times 10^3$  J/mol; the reaction proceeds to the left to reach equilibrium. **20.81**(a) scene 1 (b) scene 3 > scene 1 > scene 2 **20.83**(a) no  $T$  (b) 163 kJ (c)  $1 \times 10^2$  kJ/mol **20.86**(a) spontaneous (b) + (c) + (d) - (e) -, not spontaneous (f) - **20.90**(a)  $2.3 \times 10^2$  (b) The treatment is to administer oxygen-rich air; increasing the concentration of oxygen shifts the equilibrium to the left, in the direction of Hb·O<sub>2</sub>. **20.92**  $-370.$  kJ **20.94**(a)  $2\text{N}_2\text{O}_5(\text{g}) + 6\text{F}_2(\text{g}) \longrightarrow 4\text{NF}_3(\text{g}) + 5\text{O}_2(\text{g})$  (b)  $\Delta G_{\text{rxn}}^\circ = -569$  kJ (c)  $\Delta G_{\text{rxn}}^\circ = -5.60 \times 10^2$  kJ/mol **20.96**  $\Delta H_{\text{rxn}}^\circ = -137.14$  kJ;  $\Delta S_{\text{rxn}}^\circ = -120.3$  J/K;  $\Delta G_{\text{rxn}}^\circ = -101.25$  kJ **20.104**(a)  $1.67 \times 10^3$  J/mol (b)  $7.37 \times 10^3$  J/mol (c)  $-4.04 \times 10^3$  J/mol (d) 0.19 **20.108**(a) 465 K (b)  $6.59 \times 10^{-4}$  (c) The reaction rate is higher at the higher temperature. The shorter time required (kinetics) overshadows the lower yield (thermodynamics). **20.112** 1.18 J/K **20.114** 7.63 J/K **20.116** 24.1 J/K

## Chapter 21

**Answers to Boxed Reading Problems: B21.1**(a) reduction:

• **21.1** Oxidation is the loss of electrons and results in a higher oxidation number; reduction is the gain of electrons and results

in a lower oxidation number. **21.3** No, one half-reaction cannot take place independently because there is a transfer of electrons from one substance to another. If one substance loses electrons, another substance must gain them. **21.6** To remove  $\text{H}^+$  ions from an equation, add an equal number of  $\text{OH}^-$  ions to both sides to neutralize the  $\text{H}^+$  ions and produce water. **21.8** Spontaneous reactions, for which  $\Delta G_{\text{sys}} < 0$ , take place in voltaic cells (also called galvanic cells). Nonspontaneous reactions, for which  $\Delta G_{\text{sys}} > 0$ , take place in electrolytic cells. **21.10**(a)  $\text{Cl}^-$  (b)  $\text{MnO}_4^-$  (c)  $\text{MnO}_4^-$  (d)  $\text{Cl}^-$  (e) from  $\text{Cl}^-$  to  $\text{MnO}_4^-$  (f)  $8\text{H}_2\text{SO}_4(\text{aq}) + 2\text{KMnO}_4(\text{aq}) + 10\text{KCl}(\text{aq}) \longrightarrow 2\text{MnSO}_4(\text{aq}) + 5\text{Cl}_2(\text{g}) + 8\text{H}_2\text{O}(\text{l}) + 6\text{K}_2\text{SO}_4(\text{aq})$

Oxidizing agent is  $\text{ClO}_3^-$  and reducing agent is  $\text{I}^-$ .

Oxidizing agent is  $\text{MnO}_4^-$  and reducing agent is  $\text{SO}_3^{2-}$ .

Oxidizing agent is  $\text{MnO}_4^-$  and reducing agent is  $\text{H}_2\text{O}_2$ .

Oxidizing agent is  $\text{Cr}_2\text{O}_7^{2-}$  and reducing agent is  $\text{Zn}$ .

Oxidizing agent is  $\text{MnO}_4^-$  and reducing agent is  $\text{Fe}(\text{OH})_2$ .

Oxidizing agent is  $\text{NO}_3^-$  and reducing agent is  $\text{Zn}$ .

Oxidizing agent is  $\text{NO}_3^-$  and reducing agent is  $\text{Sb}$ .

Oxidizing agent is  $\text{BiO}_3^-$  and reducing agent is  $\text{Mn}^{2+}$ .

Oxidizing agent is  $\text{Pb}(\text{OH})_3^-$  and reducing agent is  $\text{Fe}(\text{OH})_2$ .

Oxidizing agent is  $\text{MnO}_4^-$  and reducing agent is  $\text{As}_4\text{O}_6$ .

$\text{P}_4$  is both the oxidizing agent and the reducing agent.

Oxidizing agent is  $\text{MnO}_4^-$  and reducing agent is  $\text{CN}^-$ .

(b) Oxidizing agent is  $\text{NO}_3^-$  and reducing agent is  $\text{Au}$ . (c)  $\text{HCl}$  provides chloride ions that combine with the gold(III) ion to form the stable  $\text{AuCl}_4^-$  complex ion. **21.22**(a) A (b) E (c) C (d) A (e) E (f) E **21.25** An active electrode is a reactant or product in the cell reaction. An inactive electrode does not take part in the reaction and is present only to conduct a current.

Platinum and graphite are commonly used for inactive electrodes.

**21.26**(a) metal A (b) metal B (c) metal A (d) Hydrogen bubbles will form when metal A is placed in acid. Metal A is a better reducing agent than metal B, so if metal B reduces  $\text{H}^+$  in acid, then metal A will reduce it also. **21.27**(a) left to right (b) left (c) right (d) Ni (e) Fe (f) Fe (g)  $1\text{ M NiSO}_4$  (h)  $\text{K}^+$  and  $\text{NO}_3^-$  (i) neither (j) from right to left

**21.36** A negative  $E_{\text{cell}}^\circ$  indicates that the redox reaction is not spontaneous at the standard state, that is,  $\Delta G^\circ > 0$ . The reverse reaction is spontaneous with  $E_{\text{cell}}^\circ > 0$ .

**21.37** Similar to other state functions,  $E^\circ$  changes sign when a reaction is reversed. Unlike  $\Delta G^\circ$ ,  $\Delta H^\circ$ , and  $S^\circ$ ,  $E^\circ$  (the ratio of energy to charge) is an intensive property. When the coefficients in a reaction are multiplied by a factor, the values of  $\Delta G^\circ$ ,  $\Delta H^\circ$ , and  $S^\circ$  are multiplied by that factor. However,  $E^\circ$  does not change because both the energy and charge are multiplied by the factor and thus their ratio remains unchanged.

(b)  $E_{\text{anode}}^\circ = E_{\text{cathode}}^\circ - E_{\text{cell}}^\circ = -0.57\text{ V} - 0.35\text{ V} = -0.92\text{ V}$

$E_{\text{cell}}^\circ = 0.28\text{ V}$ ; spontaneous

$E_{\text{cell}}^\circ = -0.13\text{ V}$ ; not spontaneous

$$E_{\text{cell}}^{\circ} = 1.73 \text{ V; spontaneous}$$

$$E_{\text{cell}}^{\circ} = -0.12 \text{ V; not spontaneous}$$

$$E_{\text{cell}}^{\circ} = 0.867 \text{ V} - (-1.66 \text{ V}) = 2.53 \text{ V}$$

$$E_{\text{cell}}^{\circ} = 2.59 \text{ V}$$

$$E_{\text{cell}}^{\circ} = 0.06 \text{ V}$$

Oxidizing agents:  $\text{Al}^{3+} < \text{N}_2\text{O}_4 < \text{SO}_4^{2-}$

Reducing agents:  $\text{SO}_3^{2-} < \text{NO}_2^- < \text{Al}$

$$E_{\text{cell}}^{\circ} = 0.43 \text{ V}$$

$$E_{\text{cell}}^{\circ} = 1.94 \text{ V}$$

$$E_{\text{cell}}^{\circ} = 1.51 \text{ V}$$

Oxidizing agents:  $\text{PbSO}_4 < \text{Pt}^{2+} < \text{HClO}$

Reducing agents:  $\text{Cl}_2 < \text{Pt} < \text{Pb}$

**21.50(a)** yes (b)  $C > A > B$  **21.53**  $\text{A}(\text{s}) + \text{B}^+(\text{aq}) \longrightarrow \text{A}^+(\text{aq}) + \text{B}(\text{s})$  with  $Q = [\text{A}^+]/[\text{B}^+]$ . (a)  $[\text{A}^+]$  increases and  $[\text{B}^+]$  decreases.

(b)  $E_{\text{cell}}$  decreases. (c)  $E_{\text{cell}} = E_{\text{cell}}^{\circ} - (RT/nF) \ln([\text{A}^+]/[\text{B}^+])$ ;

$E_{\text{cell}} = E_{\text{cell}}^{\circ}$  when  $(RT/nF) \ln([\text{A}^+]/[\text{B}^+]) = 0$ . This occurs when

$\ln([\text{A}^+]/[\text{B}^+]) = 0$ , that is,  $[\text{A}^+]$  equals  $[\text{B}^+]$ . (d) Yes, when

$[\text{A}^+] > [\text{B}^+]$ . **21.55** In a concentration cell, the overall reaction decreases the concentration of the more concentrated electrolyte because that electrolyte is reduced in the cathode compartment.

**21.56(a)**  $3 \times 10^{35}$  (b)  $4 \times 10^{-31}$  **21.58(a)**  $1 \times 10^{-67}$  (b)  $6 \times 10^9$

**21.60(a)**  $-2.03 \times 10^5 \text{ J}$  (b)  $1.74 \times 10^5 \text{ J}$  **21.62(a)**  $3.82 \times 10^5 \text{ J}$

(b)  $-5.6 \times 10^4 \text{ J}$  **21.64**  $E_{\text{cell}}^{\circ} = 0.28 \text{ V}$ ;  $\Delta G^{\circ} = -2.7 \times 10^4 \text{ J}$

**21.66**  $E_{\text{cell}}^{\circ} = 0.054 \text{ V}$ ;  $\Delta G^{\circ} = -1.0 \times 10^4 \text{ J}$  **21.68**  $8.8 \times 10^{-5} \text{ M}$

**21.70(a)**  $0.05 \text{ V}$  (b)  $0.50 \text{ M}$  (c)  $[\text{Co}^{2+}] = 0.91 \text{ M}$ ;  $[\text{Ni}^{2+}] = 0.09 \text{ M}$

**21.72** half-cell A;  $0.083 \text{ V}$  **21.74** Electrons flow from the anode, where oxidation occurs, to the cathode, where reduction occurs.

The electrons always flow from the anode to the cathode no matter what type of battery. **21.76** A D alkaline battery is larger than an AAA one, so it contains greater amounts of the cell components. The cell potential is an intensive property and does not depend on the amounts of the cell components. The total charge, however, does depend on the amount of cell components, so the D battery produces more charge. **21.78** The Teflon spacers keep the two metals separated so that the copper cannot conduct electrons that would promote the corrosion (rusting) of the iron skeleton. **21.81** Sacrificial anodes are made of metals that have  $E^{\circ}$  less than that of iron,  $-0.44 \text{ V}$ , so they are more easily oxidized than iron. Only (b), (f), and (g) will work for iron:

(a) will form an oxide coating that prevents further oxidation; (c) will react with groundwater quickly; (d) and (e) are less easily oxidized than iron. **21.83** To reverse the reaction requires  $0.34 \text{ V}$  with the cell in its standard state. A  $1.5\text{-V}$  cell supplies more than enough potential, so the Cd metal is oxidized to  $\text{Cd}^{2+}$  and Cr

metal plates out. **21.85** The oxidation number of N in  $\text{NO}_3^-$  is +5, the maximum O.N. for N. In the nitrite ion,  $\text{NO}_2^-$ , the O.N. of N is +3, so nitrogen can be further oxidized. **21.87(a)**  $\text{Br}_2$  (b) Na **21.89**  $\text{I}_2$  gas forms at the anode; magnesium (liquid) forms at the cathode. **21.91** Bromine gas forms at the anode; calcium metal forms at the cathode.

**21.93** copper and bromine **21.95** iodine, zinc, and silver

**21.101(a)**  $3.75 \text{ mol e}^-$  (b)  $3.62 \times 10^5 \text{ C}$  (c)  $28.7 \text{ A}$

**21.103**  $0.275 \text{ g Ra}$  **21.105**  $9.20 \times 10^3 \text{ s}$  **21.107(a)** The sodium and sulfate ions conduct a current, facilitating electrolysis. Pure water, which contains very low ( $10^{-7} \text{ M}$ ) concentrations of  $\text{H}^+$  and  $\text{OH}^-$ , conducts electricity very poorly. (b) The reduction of  $\text{H}_2\text{O}$  has a more positive half-potential than does the reduction of  $\text{Na}^+$ ; the oxidation of  $\text{H}_2\text{O}$  is the only reaction possible because  $\text{SO}_4^{2-}$  cannot be oxidized. Thus, it is easier to reduce  $\text{H}_2\text{O}$  than  $\text{Na}^+$  and easier to oxidize  $\text{H}_2\text{O}$  than  $\text{SO}_4^{2-}$ . **21.109**  $62.6 \text{ g Zn}$  **21.111(a)**  $3.3 \times 10^{11} \text{ C}$

(b)  $4.8 \times 10^{11} \text{ J}$  (c)  $1.2 \times 10^4 \text{ kg}$  **21.114**  $64.3 \text{ mass \% Cu}$

**21.115(a)** 8 days (b) 32 days (c) \$940 **21.118(a)**  $2.4 \times 10^4$  days

(b)  $2.1 \text{ g}$  (c)  $6.1 \times 10^{-5}$  dollars **21.121(a)**  $\text{Pb}/\text{Pb}^{2+}$ :  $E_{\text{cell}}^{\circ} = 0.13 \text{ V}$ ;

$\text{Cu}/\text{Cu}^{2+}$ :  $E_{\text{cell}}^{\circ} = 0.34 \text{ V}$  (b) The anode (negative electrode) is Pb.

The anode in the other cell is platinum in the standard hydrogen electrode. (c) The precipitation of PbS decreases  $[\text{Pb}^{2+}]$ , which increases the potential. (d)  $-0.13 \text{ V}$  **21.124** The three steps equivalent to the overall reaction

The energy for step 3 is similar for all three elements, so the difference in energy for the overall reaction depends on the values for  $\Delta H_{\text{hydration}}$  and IE. The  $\text{Li}^+$  ion has a greater hydration energy than  $\text{Na}^+$  and  $\text{K}^+$  because it is smaller, with a larger charge density that holds the water molecules more tightly. The energy required to remove the waters surrounding  $\text{Li}^+$  offsets the lower ionization energy, making the overall energy for the reduction of  $\text{Li}^+$  ion larger than expected. **21.125** The very high and very low standard electrode potentials involve extremely reactive substances, such as  $\text{F}_2$  (a powerful oxidizer) and Li (a powerful reducer). These substances react directly with water because any aqueous cell with a voltage of more than  $1.23 \text{ V}$  has the ability to electrolyze water into hydrogen and oxygen. **21.127(a)**  $1.073 \times 10^5 \text{ s}$  (b)  $1.5 \times 10^4 \text{ kW}\cdot\text{h}$  (c)  $0.92\text{¢}$  **21.129** If metal E and a salt of metal F are mixed, the salt is reduced, producing metal F because E has the greatest reducing strength of the three metals;  $F < D < E$ .

**21.131(a)** Cell I: 4 mol electrons;  $\Delta G = -4.75 \times 10^5 \text{ J}$

Cell II: 2 mol electrons;  $\Delta G = -3.94 \times 10^5 \text{ J}$

Cell III: 2 mol electrons;  $\Delta G = -4.53 \times 10^5 \text{ J}$

- (b) Cell I:  $-13.2$  kJ/g  
 Cell II:  $-0.613$  kJ/g  
 Cell III:  $-2.63$  kJ/g  
 Cell I has the highest ratio (most energy released per gram) because the reactants have very low mass, while cell II has the lowest ratio because the reactants have large masses.

**21.135**(a)  $9.7$  g Cu (b)  $0.56$  M  $\text{Cu}^{2+}$  **21.136**  $2.94$

**21.141**(a)  $3.6 \times 10^{-9}$  M (b)  $0.3$  M

**21.143**(a) Nonstandard cell:

$$E_{\text{waste}} = E_{\text{cell}}^{\circ} - (0.0592 \text{ V/1}) \log [\text{Ag}^+]_{\text{waste}}$$

Standard cell:

$$E_{\text{standard}} = E_{\text{cell}}^{\circ} - (0.0592 \text{ V/1}) \log [\text{Ag}^+]_{\text{standard}}$$

$$(b) [\text{Ag}^+]_{\text{waste}} = \text{antilog} \left( \frac{E_{\text{standard}} - E_{\text{waste}}}{0.0592} \right) [\text{Ag}^+]_{\text{standard}}$$

$$(c) C_{\text{Ag}^+, \text{waste}} = \text{antilog} \left( \frac{E_{\text{standard}} - E_{\text{waste}}}{0.0592} \right) C_{\text{Ag}^+, \text{standard}},$$

where  $C$  is concentration in ng/L

(d)  $900$  ng/L

(e)  $[\text{Ag}^+]_{\text{waste}} =$

$$\text{antilog} \left[ \frac{(E_{\text{standard}} - E_{\text{waste}}) \frac{nF}{2.303R} + T_{\text{standard}} \log [\text{Ag}^+]_{\text{standard}}}{T_{\text{waste}}} \right]$$

**21.145**(a)  $1.08 \times 10^3$  C (b)  $0.629$  g Cd,  $1.03$  g NiO(OH),  $0.202$  g  $\text{H}_2\text{O}$ ; total mass of reactants =  $1.86$  g (c)  $10.1\%$

**21.147**  $\text{Li} > \text{Ba} > \text{Na} > \text{Al} > \text{Mn} > \text{Zn} > \text{Cr} > \text{Fe} > \text{Ni} > \text{Sn} > \text{Pb} > \text{Cu} > \text{Ag} > \text{Hg} > \text{Au}$ . Metals with potentials lower than that of water ( $-0.83$  V) can displace  $\text{H}_2$  from water: Li, Ba, Na, Al, and Mn. Metals with potentials lower than that of hydrogen ( $0.00$  V) can displace  $\text{H}_2$  from acid: Li, Ba, Na, Al, Mn, Zn, Cr, Fe, Ni, Sn, and Pb. Metals with potentials greater than that of hydrogen ( $0.00$  V) cannot displace  $\text{H}_2$ : Cu, Ag, Hg, and Au.

**21.150**(a)  $5.3 \times 10^{-11}$  (b)  $0.20$  V (c)  $0.43$  V (d)  $8.2 \times 10^{-4}$  M NaOH **21.153**(a)  $-1.18 \times 10^5$  kJ (b)  $1.20 \times 10^4$  L (c)  $9.43 \times 10^4$  s (d)  $157$  kW·h (e)  $22.0$ ¢

## Chapter 22

**22.2** Fe from  $\text{Fe}_2\text{O}_3$ ; Ca from  $\text{CaCO}_3$ ; Na from NaCl; Zn from ZnS **22.3**(a) Differentiation refers to the processes involved in the formation of Earth into regions (core, mantle, and crust) of differing composition. Substances separated according to their densities, with the more dense material in the core and the less dense in the crust. (b) O, Si, Al, and Fe (c) O **22.7** Plants produced  $\text{O}_2$ , slowly increasing the oxygen concentration in the atmosphere and creating an environment for oxidizing metals. The oxygen-free decay of plant and animal material created large fossil fuel deposits. **22.9** Fixation refers to the process of converting a substance in the atmosphere into a form more readily usable by organisms. Carbon and nitrogen; fixation of carbon dioxide gas by plants and fixation of nitrogen gas by nitrogen-fixing bacteria. **22.12** Atmospheric nitrogen is fixed by three pathways: atmospheric, industrial, and biological.

Atmospheric fixation requires high-temperature reactions (e.g., initiated by lightning) to convert  $\text{N}_2$  into NO and other oxidized species. Industrial fixation involves mainly the formation of ammonia,  $\text{NH}_3$ , from  $\text{N}_2$  and  $\text{H}_2$ . Biological fixation occurs in nitrogen-fixing bacteria that live on the roots of legumes. Human activity is an example of industrial fixation. It contributes about 17% of the fixed nitrogen. **22.14**(a) the atmosphere (b) Plants excrete acid from their roots to convert  $\text{PO}_4^{3-}$  ions into more soluble  $\text{H}_2\text{PO}_4^-$  ions, which the plant can absorb. Through excretion and decay, organisms return soluble phosphate compounds to the cycle. **22.17**(a)  $1.1 \times 10^3$  L (b)  $4.2 \times 10^2$  m<sup>3</sup> **22.18**(a) The iron(II) ions form an insoluble salt,  $\text{Fe}_3(\text{PO}_4)_2$ , that decreases the yield of phosphorus. (b)  $8.8$  t **22.20**(a) Roasting consists of heating a mineral sulfide in air at high temperatures to convert it to the oxide. (b) Smelting is the reduction of the metal oxide to the free metal using heat and a reducing agent such as coke. (c) Flotation is a separation process in which the ore is removed from the gangue by exploiting the difference in density in the presence of detergent. The gangue sinks to the bottom and the lighter ore-detergent mix is skimmed off the top. (d) Refining, using electricity or heat, is the final step in the process to yield the pure element. **22.25**(a) Slag is a byproduct of steel-making and contains the impurity  $\text{SiO}_2$ . (b) Pig iron is the impure product of iron metallurgy (containing 3–4% C and other impurities). (c) Steel refers to iron that has been alloyed with other elements to give the metal desirable properties. (d) The basic-oxygen process is used to purify pig iron and obtain carbon steel. **22.27** Iron and nickel are more easily oxidized and less easily reduced than copper. They are separated from copper in the roasting step and converted to slag. In the electrorefining process, all three metals are in solution, but only  $\text{Cu}^{2+}$  ions are reduced at the cathode to form Cu(s). **22.30** Le Châtelier's principle says that the system shifts toward formation of K as the gaseous metal leaves the cell. **22.31**(a)  $E_{\text{half-cell}}^{\circ} = -3.05$  V,  $-2.93$  V, and  $-2.71$  V for  $\text{Li}^+$ ,  $\text{K}^+$ , and  $\text{Na}^+$ , respectively. In all of these cases, it is energetically more favorable to reduce  $\text{H}_2\text{O}$  to  $\text{H}_2$  than to reduce  $\text{M}^+$  to M. (b)  $2\text{RbX} + \text{Ca} \longrightarrow \text{CaX}_2 + 2\text{Rb}$  where  $\Delta H = \text{IE}_1(\text{Ca}) + \text{IE}_2(\text{Ca}) - 2\text{IE}_1(\text{Rb}) = 929$  kJ/mol. Based on the IEs and positive  $\Delta H$  for the forward reaction, it seems more reasonable that Rb metal will reduce  $\text{Ca}^{2+}$  than the reverse. (c) If the reaction is carried out at a temperature greater than the boiling point of Rb, the product mixture will contain gaseous Rb, which can be removed from the reaction vessel; this would cause a shift in equilibrium to form more Rb as product. (d)  $2\text{CsX} + \text{Ca} \longrightarrow \text{CaX}_2 + 2\text{Cs}$ , where  $\Delta H = \text{IE}_1(\text{Ca}) + \text{IE}_2(\text{Ca}) - 2\text{IE}_1(\text{Cs}) = 983$  kJ/mol. This reaction is less favorable than for Rb, but Cs has a lower boiling point. **22.32**(a)  $4.5 \times 10^4$  L (b)  $1.30 \times 10^8$  C (c)  $1.69 \times 10^6$  s **22.35**(a)  $\text{Mg}^{2+}$  is more difficult to reduce than  $\text{H}_2\text{O}$ , so  $\text{H}_2(\text{g})$  would be produced instead of Mg metal.  $\text{Cl}_2(\text{g})$  forms at the anode due to overvoltage. (b) The  $\Delta H_f^{\circ}$  of  $\text{MgCl}_2(\text{s})$  is  $-641.6$  kJ/mol. High temperature favors the reverse (endothermic) reaction, the formation of magnesium metal and chlorine gas. **22.37**(a) Sulfur dioxide is the reducing agent and is oxidized to the +6 state ( $\text{SO}_4^{2-}$ ). (b)  $\text{HSO}_4^-(\text{aq})$  (c)  $\text{H}_2\text{SeO}_3(\text{aq}) + 2\text{SO}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{Se}(\text{s}) + 2\text{HSO}_4^-(\text{aq}) + 2\text{H}^+(\text{aq})$  **22.42**(a) O.N. for Cu: in  $\text{Cu}_2\text{S}$ , +1; in  $\text{Cu}_2\text{O}$ , +1; in Cu, 0 (b)  $\text{Cu}_2\text{S}$  is the reducing agent, and  $\text{Cu}_2\text{O}$  is the oxidizing agent.

**22.47**  $2\text{ZnS}(s) + \text{C}(\text{graphite}) \longrightarrow 2\text{Zn}(s) + \text{CS}_2(g)$ ;  $\Delta G_{\text{rxn}}^{\circ} = 463 \text{ kJ}$ . Since  $\Delta G_{\text{rxn}}^{\circ}$  is positive, this reaction is not spontaneous at standard-state conditions.  $2\text{ZnO}(s) + \text{C}(s) \longrightarrow 2\text{Zn}(s) + \text{CO}_2(g)$ ;  $\Delta G_{\text{rxn}}^{\circ} = 242.0 \text{ kJ}$ . This reaction is also not spontaneous, but is less unfavorable. **22.48** The formation of sulfur trioxide is very slow at ordinary temperatures. Increasing the temperature can speed up the reaction, but because the reaction is exothermic, increasing the temperature decreases the yield. Adding a catalyst increases the rate of the reaction, allowing a lower temperature to be used to enhance the yield. **22.51**(a)  $\text{Cl}_2$ ,  $\text{H}_2$ , and  $\text{NaOH}$  (b) The mercury-cell method yields higher purity  $\text{NaOH}$ , but releases some  $\text{Hg}$ , which is harmful in the environment.

**22.52**(a)  $\Delta G^{\circ} = -142 \text{ kJ}$ ; yes (b) The rate of the reaction is very low at  $25^{\circ}\text{C}$ . (c)  $\Delta G_{500}^{\circ} = -53 \text{ kJ}$ , so the reaction is spontaneous. (d)  $K_{25} = 7.8 \times 10^{24} > K_{500} = 3.8 \times 10^3$  (e)  $1.05 \times 10^3 \text{ K}$

**22.53**  $7 \times 10^2 \text{ lb Cl}_2$  **22.56**(a)  $\text{P}_4\text{O}_{10}(s) + 6\text{H}_2\text{O}(l) \longrightarrow 4\text{H}_3\text{PO}_4(l)$  (b) 1.52 **22.58**(a)  $9.006 \times 10^9 \text{ g CO}_2$  (b) The  $4.3 \times 10^{10} \text{ g CO}_2$  produced by automobiles is much greater than that from the blast furnace. **22.60**(a) If  $[\text{OH}^-] > 1.1 \times 10^{-4} \text{ M}$  (i.e., if  $\text{pH} > 10.04$ ),  $\text{Mg}(\text{OH})_2$  will precipitate. (b) 1 (To the correct number of significant figures, all the magnesium precipitates.)

**22.61**(a)  $K_{25}(\text{step 1}) = 1 \times 10^{168}$ ;  $K_{25}(\text{side rxn}) = 7 \times 10^{228}$  (b)  $K_{900}(\text{step 1}) = 4.5 \times 10^{49}$ ;  $K_{900}(\text{side rxn}) = 1.4 \times 10^{63}$  (c)  $8.8 \times 10^7$  dollars (d)  $6.4 \times 10^7$  dollars **22.64**(1)  $2\text{H}_2\text{O}(l) + 2\text{FeS}_2(s) + 7\text{O}_2(g) \longrightarrow 2\text{Fe}^{2+}(aq) + 4\text{SO}_4^{2-}(aq) + 4\text{H}^+(aq)$  increases acidity (2)  $4\text{H}^+(aq) + 4\text{Fe}^{2+}(aq) + \text{O}_2(g) \longrightarrow 4\text{Fe}^{3+}(aq) + 2\text{H}_2\text{O}(l)$  (3)  $\text{Fe}^{3+}(aq) + 3\text{H}_2\text{O}(l) \longrightarrow \text{Fe}(\text{OH})_3(s) + 3\text{H}^+(aq)$  increases acidity (4)  $8\text{H}_2\text{O}(l) + \text{FeS}_2(s) + 14\text{Fe}^{3+}(aq) \longrightarrow 15\text{Fe}^{2+}(aq) + 2\text{SO}_4^{2-}(aq) + 16\text{H}^+(aq)$  increases acidity

**22.65** density of ferrite:  $7.86 \text{ g/cm}^3$ ; density of austenite:  $7.55 \text{ g/cm}^3$  **22.67**(a) Cathode:  $\text{Na}^+(l) + e^- \longrightarrow \text{Na}(l)$

Anode:  $4\text{OH}^-(l) \longrightarrow \text{O}_2(g) + 2\text{H}_2\text{O}(g) + 4e^-$  (b) 50%

**22.70**(a)  $n\text{CO}_2(g) + n\text{H}_2\text{O}(l) \longrightarrow (\text{CH}_2\text{O})_n(s) + n\text{O}_2(g)$

(b) 27 L (c)  $6.7 \times 10^4 \text{ L}$  **22.71** 73 mg/L **22.72** 891 kg  $\text{Na}_3\text{AlF}_6$

**22.73**(a) 23.2 min (b) 14 effusion steps **22.75**(a) 1.890 t

$\text{Al}_2\text{O}_3$  (b) 0.3339 t C (c) 100% (d) 74% (e)  $2.813 \times 10^3$

$\text{m}^3$  **22.80** Acid rain increases the leaching of phosphate into the groundwater, due to the protonation of  $\text{PO}_4^{3-}$  to form  $\text{HPO}_4^{2-}$  and  $\text{H}_2\text{PO}_4^-$ . As shown in calculations for parts (a) and (b), solubility of  $\text{Ca}_3(\text{PO}_4)_2$  increases more than  $10^4$  from the value in pure water to the value in acidic rainwater. (a)  $6.4 \times 10^{-7} \text{ M}$  (b)  $1.1 \times 10^{-2} \text{ M}$

**22.81**(a) 1.00 mol % (b) 238.9 g/mol **22.83** density of silver =  $10.51 \text{ g/cm}^3$ ; density of sterling silver =  $10.2 \text{ g/cm}^3$

## Chapter 23

**Answers to Boxed Reading Problems B23.2** Zinc forms tetrahedral complex ions. The other ions listed form ions of other geometries ( $\text{Ni}^{2+}$  forms square planar complex ions while  $\text{Fe}^{2+}$  and  $\text{Mn}^{2+}$  form octahedral complex ions). If these ions are placed in a tetrahedral environment in place of the zinc, they cannot function as well as zinc since the enzyme catalyst would have a different shape.

• **23.2**(a)  $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^x$

(b)  $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^{10} 5p^6 6s^2 4f^{14} 5d^x$  **23.4** Five;

examples are Mn:  $[\text{Ar}] 4s^2 3d^5$  and  $\text{Fe}^{3+}$ :  $[\text{Ar}] 3d^5$ . **23.6**(a) The elements should increase in size as they increase in mass from Period 5 to Period 6. Because there are 14 inner transition elements in Period 6, the effective nuclear charge increases

significantly; so the atomic size decreases, or “contracts.” This effect is significant enough that  $\text{Zr}^{4+}$  and  $\text{Hf}^{4+}$  are almost the same size but differ greatly in atomic mass. (b) The atomic size increases from Period 4 to Period 5, but stays fairly constant from Period 5 to Period 6. (c) Atomic mass increases significantly from Period 5 to Period 6, but atomic radius (and thus volume) increases slightly, so Period 6 elements are very dense.

**23.9**(a) A paramagnetic substance is attracted to a magnetic field, while a diamagnetic substance is slightly repelled by one. (b) Ions of transition elements often have half-filled  $d$  orbitals whose unpaired electrons make the ions paramagnetic. Ions of main-group elements usually have a noble-gas configuration with no partially filled levels. (c) Some  $d$  orbitals in the transition element ions are empty, which allows an electron from one  $d$  orbital to move to a slightly higher energy one. The energy required is small and falls in the visible range, so the ion is colored. All orbitals are filled in ions of main-group elements, so enough energy would have to be added to move an electron to the next principal energy level, not just another orbital within the same energy level. This amount of energy is very large and much greater than the visible range of wavelengths.

**23.10**(a)  $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^3$  or  $[\text{Ar}] 4s^2 3d^3$

(b)  $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^1$  or  $[\text{Kr}] 5s^2 4d^1$

(c)  $[\text{Xe}] 6s^2 4f^{14} 5d^{10}$  **23.12**(a)  $[\text{Xe}] 6s^2 4f^{14} 5d^6$  (b)  $[\text{Ar}] 4s^2 3d^7$

(c)  $[\text{Kr}] 5s^1 4d^{10}$  **23.14**(a)  $[\text{Ar}]$ , no unpaired electrons

(b)  $[\text{Ar}] 3d^9$ , one unpaired electron (c)  $[\text{Ar}] 3d^5$ , five unpaired electrons (d)  $[\text{Kr}] 4d^2$ , two unpaired electrons **23.16**(a) +5

(b) +4 (c) +7 **23.18** Cr, Mo, and W **23.20** in  $\text{CrF}_2$ , because Cr is in a lower oxidation state in that compound **23.22** Atomic size increases slightly down a group of transition elements, but nuclear charge increases much more, so the first ionization energy generally increases. Since the ionization energy of Mo is higher than that of Cr, so it is more difficult to remove electrons from Mo. Also, the reduction potential for Mo is less negative, so it is more difficult to oxidize Mo than Cr. **23.24**  $\text{CrO}_3$ , with Cr in a higher oxidation state, yields a more acidic aqueous solution. **23.28**(a) seven (b) The number corresponds to a half-filled  $f$  subshell. **23.30**(a)  $[\text{Xe}] 6s^2 5d^1$  (b)  $[\text{Xe}] 4f^1$  (c)  $[\text{Rn}] 7s^2 5f^{11}$

(d)  $[\text{Rn}] 5f^2$  **23.32**(a)  $\text{Eu}^{2+}$ :  $[\text{Xe}] 4f^7$ ;  $\text{Eu}^{3+}$ :  $[\text{Xe}] 4f^6$ ;  $\text{Eu}^{4+}$ :  $[\text{Xe}] 4f^5$ . The stability of the half-filled  $f$  subshell makes  $\text{Eu}^{2+}$  most stable. (b)  $\text{Tb}^{2+}$ :  $[\text{Xe}] 4f^9$ ;  $\text{Tb}^{3+}$ :  $[\text{Xe}] 4f^8$ ;  $\text{Tb}^{4+}$ :  $[\text{Xe}] 4f^7$ . Tb should show a +4 oxidation state because that corresponds to a half-filled subshell. **23.34** Gd has the electron configuration  $[\text{Xe}] 6s^2 4f^7 5d^1$  with eight unpaired electrons.  $\text{Gd}^{3+}$  has seven unpaired electrons:  $[\text{Xe}] 4f^7$ . **23.37** The coordination number indicates the number of ligand atoms bonded to the metal ion. The oxidation number represents the number of electrons lost to form the ion. The coordination number is unrelated to the oxidation number. **23.39** 2, linear; 4, tetrahedral or square planar; 6, octahedral **23.42** The complex ion has a negative charge.

**23.45**(a) hexaaquanickel(II) chloride (b) tris(ethylenediamine) chromium(III) perchlorate (c) potassium hexacyanomanganate(II)

**23.47**(a) 2+, 6 (b) 3+, 6 (c) 2+, 6 **23.49**(a) potassium dicyanoargentate(I) (b) sodium tetrachlorocadmiate(II) (c) tetraammineaquabromocobalt(III) bromide **23.51**(a) 1+, 2 (b) 2+, 4 (c) 3+, 6 **23.53**(a)  $[\text{Zn}(\text{NH}_3)_4]\text{SO}_4$  (b)  $[\text{Cr}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$  (c)  $\text{Na}_3[\text{Ag}(\text{S}_2\text{O}_3)_2]$  **23.55**(a) 4, two ions (b) 6, three ions

- (c) 2, four ions **23.57**(a)  $[\text{Cr}(\text{H}_2\text{O})_6]_2(\text{SO}_4)_3$  (b)  $\text{Ba}[\text{FeBr}_4]_2$   
 (c)  $[\text{Pt}(\text{en})_2]\text{CO}_3$  **23.59**(a) 6, five ions (b) 4, three ions  
 (c) 4, two ions **23.61**(a) The nitrite ion forms linkage isomers because it can bind to the metal ion through the lone pair on the N atom or any lone pair on either O atom.  $[\text{:}\ddot{\text{O}}-\ddot{\text{N}}=\ddot{\text{O}}\text{:}]^-$   
 (b) Sulfur dioxide molecules form linkage isomers because the lone pair on the S atom or any lone pair on either O atom can bind the central metal ion.  $\ddot{\text{O}}=\ddot{\text{S}}=\ddot{\text{O}}$  (c) Nitrate ions have an N atom with no lone pair and three O atoms, all with lone pairs that can bind to the metal ion. But all of the O atoms are equivalent, so these ions do not form linkage isomers.  $[\text{:}\ddot{\text{O}}-\text{N}(\ddot{\text{O}})=\ddot{\text{O}}\text{:}]^-$

**23.63**(a) geometric isomerism

(b) geometric isomerism

(c) geometric isomerism

**23.65**(a) geometric isomerism

(b) linkage isomerism

(c) geometric isomerism

**23.67** The compound with the traditional formula is  $\text{CrCl}_3 \cdot 4\text{NH}_3$ ; the modern formula is  $[\text{Cr}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}$ . **23.69**(a)  $\text{K}[\text{Pd}(\text{NH}_3)\text{Cl}_3]$   
 (b)  $[\text{PdCl}_2(\text{NH}_3)_2]$  (c)  $\text{K}_2[\text{PdCl}_6]$  (d)  $[\text{Pd}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}_2$

**23.71**(a)  $dsp^2$  (b)  $sp^3$  **23.74** Absorption of orange light or absorption of all colors of light except blue will give a solution a blue color. **23.75**(a) The crystal field splitting energy ( $\Delta$ ) is the energy difference between the two sets of  $d$  orbitals that result from electrostatic effects of ligands on a central transition metal atom. (b) In an octahedral field of ligands, the ligands approach along the  $x$ ,  $y$ , and  $z$  axes. The  $d_{x^2-y^2}$  and  $d_z^2$  orbitals are located along the  $x$ ,  $y$ , and  $z$  axes, so ligand interactions there are higher

in energy. The other ligand interactions are lower in energy because the  $d_{xy}$ ,  $d_{yz}$ , and  $d_{xz}$  orbitals are located *between* the  $x$ ,  $y$ , and  $z$  axes. (c) In a tetrahedral field of *ligands*, the ligands do not approach along the  $x$ ,  $y$ , and  $z$  axes. The ligand interaction is greater for the  $d_{xy}$ ,  $d_{yz}$ , and  $d_{xz}$  orbitals and lesser for the  $d_{x^2-y^2}$  and  $d_z^2$  orbitals. Therefore, the crystal field splitting is *reversed*, and the  $d_{xy}$ ,  $d_{yz}$ , and  $d_{xz}$  orbitals are higher in energy than the  $d_{x^2-y^2}$  and  $d_z^2$  orbitals. **23.78** If  $\Delta$  is greater than  $E_{\text{pairing}}$ , electrons will pair their spins in the lower energy set of  $d$  orbitals before entering the higher energy set of  $d$  orbitals as unpaired electrons. If  $\Delta$  is less than  $E_{\text{pairing}}$ , electrons will occupy the higher energy set of  $d$  orbitals as unpaired electrons before pairing in the lower energy set of  $d$  orbitals. **23.80**(a) no  $d$  electrons (b) eight  $d$  electrons (c) six  $d$  electrons **23.82**(a) five (b) ten (c) seven

**23.84**

In an octahedral field of ligands, the ligands approach along the  $x$ ,  $y$ , and  $z$  axes. The lobes of the  $d_{x^2-y^2}$  orbital lie *along* the  $x$  and  $y$  axes, so ligand interaction is greater. The lobes of the  $d_{xy}$  orbital lie *between* the  $x$  and  $y$  axes, so ligand interaction is less. The greater interaction of the  $d_{x^2-y^2}$  orbital results in its higher energy. **23.86** a and d

**23.88**(a)

(b)

(c)

**23.90**(a)

(b)

(c)

**23.92**  $[\text{Cr}(\text{H}_2\text{O})_6]^{3+} < [\text{Cr}(\text{NH}_3)_6]^{3+} < [\text{Cr}(\text{NO}_2)_6]^{3-}$

**23.94** A violet complex absorbs yellow-green light. The light absorbed by a complex with a weaker field ligand would have a lower energy and a higher wavelength. Light of lower energy than yellow-green light is yellow, orange, or red. The color observed would be blue or green. **23.97**  $\text{H}_2\text{O}$  is a weak-field ligand, somewhat weaker than  $\text{NH}_3$ . A weak-field ligand results in a lower splitting energy, and the complex absorbs visible light of lower energy. The hexaqua complex appears green because it absorbs red light. The hexammine complex appears violet because it absorbs yellow light, which has higher energy (shorter  $\lambda$ ) than red light. **23.101**  $\text{Hg}^+$  is  $[\text{Xe}] 6s^1 4f^{14} 5d^{10}$  and  $\text{Cu}^+$  is  $[\text{Ar}] 3d^{10}$ . The mercury(I) ion has one electron in the  $6s$  orbital that can form a covalent bond with the electron in the  $6s$  orbital of another mercury(I) ion. In the copper(I) ion there are no electrons in the  $s$  orbital, so these ions cannot bond with one another. **23.102**(a) 6 (b) +3 (c) two (d) 1 mol

**23.109** geometric (*cis-trans*) and linkage isomerism**23.110**  $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Cl}]^{2+}$ 

tetraammineaquachlorocobalt(III) ion

 $[\text{Cr}(\text{H}_2\text{O})_3\text{Br}_2\text{Cl}]$   
triquadribromochlorochromium(III)

3 geometric isomers

 $[\text{Cr}(\text{NH}_3)_2(\text{H}_2\text{O})_2\text{Br}_2]^+$   
diamminediaquadibromochromium(III) ion

6 isomers (5 geometric)

**23.115(a)** no optical isomers (b) no optical isomers

(c) no optical isomers (d) no optical isomers (e) optical isomers

**23.116**  $\text{Pt}[\text{P}(\text{C}_2\text{H}_5)_3]_2\text{Cl}_2$ 

**23.118(a)** The first reaction shows no change in the number of particles. In the second reaction, the number of reactant particles is greater than the number of product particles. A decrease in the number of particles means a decrease in entropy. Based on entropy change only, the first reaction is favored. (b) The ethylenediamine complex will be more stable with respect to ligand exchange in water because the entropy change for that exchange is unfavorable (negative).

**Chapter 24**

**Answers to Boxed Reading Problems: B24.1** In the *s*-process, a nucleus captures a neutron at some point over a long period of time. Then the nucleus emits a  $\beta^-$  particle to form another element. The stable isotopes of most heavy elements up to  $^{209}\text{Bi}$  form by the *s*-process. The *r*-process very quickly forms less stable isotopes and those with *A* greater than 230 by multiple neutron captures, followed by multiple  $\beta^-$  decays. **B24.3** The simultaneous fusion of three nuclei is a termolecular process. Termolecular processes have a very low probability of occurring. The bimolecular fusion of  $^8\text{Be}$  with  $^4\text{He}$  is more likely.

**B24.4**  $^{210}_{83}\text{Bi} \rightarrow ^0_{-1}\beta + ^{210}_{84}\text{Po}$  (nuclide A);  $^{210}_{84}\text{Po} \rightarrow ^4_2\alpha + ^{206}_{82}\text{Pb}$  (nuclide B);  $^{206}_{82}\text{Pb} + 3^1_0\text{n} \rightarrow ^{209}_{82}\text{Pb}$  (nuclide C);  $^{209}_{82}\text{Pb} \rightarrow ^0_{-1}\beta + ^{209}_{83}\text{Bi}$  (nuclide D)

• **24.1(a)** Chemical reactions are accompanied by relatively small changes in energy; nuclear reactions are accompanied by relatively large changes in energy. (b) Increasing temperature increases the rate of a chemical reaction but has no effect on a nuclear reaction. (c) Chemical reaction rates increase with higher reactant concentrations, while nuclear reaction rates increase with increasing number of nuclei. (d) If the reactant is limiting in a chemical reaction, then more reactant produces more product and the yield increases. The presence of more radioactive reactant results in more decay product, so a higher reactant concentration increases the yield. **24.2(a)** 95.02% (b) The atomic mass is larger than the isotopic mass of  $^{32}\text{S}$ . Sulfur-32 is the lightest isotope. **24.4(a)** *Z* down by 2, *N* down by 2 (b) *Z* up by 1, *N* down by 1 (c) no change in *Z* or *N* (d) *Z* down by 1, *N* up by 1 (e) *Z* down by 1, *N* up by 1. A different element is produced in all cases except (c). **24.6** A neutron-rich nuclide decays by  $\beta^-$  decay. A neutron-poor nuclide undergoes positron decay or electron capture. **24.8(a)**  $^{234}_{92}\text{U} \rightarrow ^4_2\alpha + ^{230}_{90}\text{Th}$  (b)  $^{232}_{93}\text{Np} + ^0_{-1}\text{e} \rightarrow ^{232}_{92}\text{U}$  (c)  $^{12}_7\text{N} \rightarrow ^0_1\beta + ^{12}_6\text{C}$  **24.10(a)**  $^{27}_{12}\text{Mg} \rightarrow ^0_{-1}\beta + ^{27}_{13}\text{Al}$  (b)  $^{23}_{12}\text{Mg} \rightarrow ^0_1\beta + ^{23}_{11}\text{Na}$  (c)  $^{103}_{46}\text{Pd} + ^0_{-1}\text{e} \rightarrow ^{103}_{45}\text{Rh}$  **24.12(a)**  $^{48}_{23}\text{V} \rightarrow ^{48}_{22}\text{Ti} + ^0_1\beta$  (b)  $^{107}_{48}\text{Cd} + ^0_{-1}\text{e} \rightarrow ^{107}_{47}\text{Ag}$  (c)  $^{210}_{86}\text{Rn} \rightarrow ^{206}_{84}\text{Po} + ^4_2\alpha$

**24.14**(a)  ${}^{186}_{78}\text{Pt} + {}^0_{-1}\text{e} \longrightarrow {}^{186}_{77}\text{Ir}$  (b)  ${}^{225}_{89}\text{Ac} \longrightarrow {}^{221}_{87}\text{Fr} + {}^4_2\alpha$   
 (c)  ${}^{129}_{52}\text{Te} \longrightarrow {}^{129}_{53}\text{I} + {}^0_{-1}\beta$  **24.16**(a) Appears stable because its  $N$  and  $Z$  values are both magic numbers, but its  $N/Z$  ratio (1.50) is too high; it is unstable. (b) Appears unstable because its  $Z$  value is an odd number, but its  $N/Z$  ratio (1.19) is in the band of stability, so it is stable. (c) Unstable because its  $N/Z$  ratio is too high. **24.18**(a) The  $N/Z$  ratio for  ${}^{127}\text{I}$  is 1.4; it is stable. (b) The  $N/Z$  ratio for  ${}^{106}\text{Sn}$  is 1.1; it is unstable because this ratio is too low. (c) The  $N/Z$  ratio is 1.1 for  ${}^{68}\text{As}$ . The ratio is within the range of stability, but the nuclide is most likely unstable because there are odd numbers of both protons and neutrons.  
**24.20**(a) alpha decay (b) positron decay or electron capture (c) positron decay or electron capture **24.22**(a)  $\beta^-$  decay (b) positron decay or electron capture (c) alpha decay  
**24.24** Stability results from a favorable  $N/Z$  ratio, even  $N$  and/or  $Z$ , and the occurrence of magic numbers. The  $N/Z$  ratio of  ${}^{52}\text{Cr}$  is 1.17, which is within the band of stability. The fact that  $Z$  is even does not account for the variation in stability because all isotopes of chromium have the same  $Z$ . However,  ${}^{52}\text{Cr}$  has 28 neutrons, so  $N$  is both an even number and a magic number for this isotope only. **24.28** seven alpha emissions and four  $\beta^-$  emissions  
**24.31** No, it is not valid to conclude that  $t_{1/2}$  equals 1 min because the number of nuclei is so small. Decay rate is an average rate and is only meaningful when the sample is macroscopic and contains a large number of nuclei. For the sample containing  $6 \times 10^{12}$  nuclei, the conclusion is valid. **24.33**  $2.56 \times 10^{-2}$  Ci/g  
**24.35**  $1.4 \times 10^8$  Bq/g **24.37**  $1 \times 10^{-12}$  day $^{-1}$  **24.39**  $2.31 \times 10^{-7}$  yr $^{-1}$   
**24.41** 1.49 mg **24.43**  $2.2 \times 10^9$  yr **24.45** 30 d/min **24.47**  $1.0 \times 10^6$  yr  
**24.50** Neither  $\gamma$  radiation nor neutron beams have charge, so neither is deflected by a magnetic or electric field. Neutron beams differ from  $\gamma$  radiation in that a neutron has a mass approximately equal to that of a proton. It was observed that a neutron beam induces the emission of protons from a substance;  $\gamma$  radiation does not cause such emission. **24.52** Protons are repelled from the target nuclei due to interaction with like (positive) charges. Higher energy is required to overcome the repulsion. **24.53**(a)  ${}^{10}_5\text{B} + {}^4_2\alpha \longrightarrow {}^1_0\text{n} + {}^{13}_7\text{N}$  (b)  ${}^{28}_{14}\text{Si} + {}^2_1\text{H} \longrightarrow {}^1_0\text{n} + {}^{29}_{15}\text{P}$  (c)  ${}^{242}_{96}\text{Cm} + {}^4_2\alpha \longrightarrow {}^1_0\text{n} + {}^{244}_{98}\text{Cf}$  **24.58** Ionizing radiation is more dangerous to children because they have rapidly dividing cells, so there is more chance for radiation to cause cell damage or mutation. **24.60**(a)  $5.4 \times 10^{-7}$  rad (b)  $5.4 \times 10^{-9}$  Gy  
**24.62**(a)  $7.5 \times 10^{-10}$  Gy (b)  $7.5 \times 10^{-5}$  mrem (c)  $7.5 \times 10^{-10}$  Sv  
**24.65**  $1.86 \times 10^{-3}$  rad **24.67** NAA does not destroy the sample, while chemical analyses do. Neutrons bombard a nonradioactive

sample, inducing some atoms within the sample to be radioactive. The radioisotopes decay by emitting radiation characteristic of each isotope. **24.73** Energy is released when a nucleus forms from nucleons. The nuclear binding energy is the quantity of energy holding 1 mol of nuclei together. This energy must be absorbed to break up the nucleus into nucleons and is released when nucleons come together. **24.75**(a)  $1.861 \times 10^4$  eV (b)  $2.981 \times 10^{-15}$  J  
**24.77**  $7.6 \times 10^{11}$  J **24.79**(a) 7.976 MeV/nucleon (b) 127.6 MeV/atom (c)  $1.231 \times 10^{10}$  kJ/mol **24.81**(a) 8.768 MeV/nucleon (b) 517.3 MeV/atom (c)  $4.99 \times 10^{10}$  kJ/mol  
**24.85** Radioactive decay is a spontaneous process in which unstable nuclei emit radioactive particles and energy. Fission occurs as the result of high-energy bombardment of nuclei that cause them to break into smaller nuclei, radioactive particles, and energy. All fission events are not the same. The nuclei split in a number of ways to produce several different products.  
**24.88** The water serves to slow the neutrons so that they are better able to cause a fission reaction. Heavy water is a better moderator because it does not absorb neutrons as well as light water does; thus, more neutrons are available to initiate the fission process. However,  $\text{D}_2\text{O}$  does not occur naturally in great abundance, so its production adds to the cost of a heavy-water reactor. **24.93**(a)  $1.1 \times 10^{-29}$  kg (b)  $9.9 \times 10^{-13}$  J (c)  $5.9 \times 10^8$  kJ/mol; this is approximately 1 million times larger than a typical heat of reaction. **24.95**  $8.0 \times 10^3$  yr  
**24.98**  $1.35 \times 10^{-5}$  M **24.100**  $6.2 \times 10^{-2}$  **24.102**(a) 5.99 h (b) 21% **24.104**(a) 0.999 (b) 0.298 (c)  $5.58 \times 10^{-6}$  (d) Radiocarbon dating is more reliable for the fraction in part (b) because a significant amount of  ${}^{14}\text{C}$  has decayed and a significant amount remains. Therefore, a change in the amount of  ${}^{14}\text{C}$  will be noticeable. For the fraction in part (a), very little  ${}^{14}\text{C}$  has decayed, and for (c) very little  ${}^{14}\text{C}$  remains. In either case, it will be more difficult to measure the change, so the error will be relatively large. **24.106** 6.58 h **24.110**  $4.904 \times 10^{-9}$  L/h **24.113** 81 yr  
**24.115**(a) 0.15 Bq/L (b) 0.27 Bq/L (c) 3.3 days; for a total of 12.8 days **24.118** 7.4 s **24.121** 1926 **24.124**  $6.27 \times 10^5$  eV/ reaction,  $6.05 \times 10^7$  kJ/mol reaction **24.127**(a)  $2.07 \times 10^{-17}$  J (b)  $1.45 \times 10^7$  H atoms (c)  $1.4960 \times 10^{-5}$  J (d)  $1.4959 \times 10^{-5}$  J (e) No, the captain should continue using the current technology. **24.130**(a) 0.043 MeV,  $2.9 \times 10^{-11}$  m (b) 4.713 MeV  
**24.134**(a)  $3.26 \times 10^3$  days (b)  $3.2 \times 10^{-3}$  s (c)  $2.78 \times 10^{11}$  yr  
**24.136**(a)  $1.80 \times 10^{17}$  J (b)  $6.15 \times 10^{16}$  kJ (c) The procedure in part (b) produces more energy per kilogram of antihydrogen.  
**24.137**  $9.316 \times 10^2$  MeV **24.141** 7.81 days

## A

**absolute scale** (See *Kelvin scale*.)

**absorption spectrum** The spectrum produced when atoms absorb specific wavelengths of incoming light and become excited from lower to higher energy levels.

**abundance** The amount of an element in a particular region of the natural world.

**accuracy** The closeness of a measurement to the actual value.

**acid** In common laboratory terms, any species that produces  $H^+$  ions when dissolved in water. (See also *Arrhenius*, *Brønsted-Lowry*, and *Lewis acid-base* definitions.)

**acid anhydride** A compound, usually formed by a dehydration-condensation reaction of an oxoacid, that yields two molecules of the acid when it reacts with water.

**acid-base buffer** (also *buffer*) A solution that resists changes in pH when a small amount of either strong acid or strong base is added.

**acid-base indicator** An organic molecule whose color is different in acid and in base; the color is used to monitor the equivalence point of a titration or the pH of a solution.

**acid-base reaction** Any reaction between an acid and a base. (See also *neutralization reaction*.)

**acid-base titration curve** A plot of the pH of a solution of acid (or base) versus the volume of base (or acid) added to the solution.

**acid-dissociation (acid-ionization) constant ( $K_a$ )** An equilibrium constant for the dissociation of an acid (HA) in  $H_2O$  to yield the conjugate base ( $A^-$ ) and  $H_3O^+$ :

$$K_a = \frac{[H_3O^+][A^-]}{[HA]}$$

**actinides** The Period 7 elements that constitute the second inner transition series (5f block), which includes thorium (Th;  $Z = 90$ ) through lawrencium (Lr;  $Z = 103$ ).

**activated complex** (See *transition state*.)

**activation energy ( $E_a$ )** The minimum energy with which molecules must collide to react.

**active site** The region of an enzyme formed by specific amino acid side chains at which catalysis occurs.

**activity ( $\mathcal{A}$ )** (also *decay rate*) The change in number of nuclei ( $\mathcal{N}$ ) of a radioactive sample divided by the change in time ( $t$ ).

**activity series of the metals** A listing of metals arranged in order of decreasing strength of the metal as a reducing agent in aqueous reactions.

**actual yield** The amount of product actually obtained in a chemical reaction.

**addition polymer** (also *chain-reaction*, or *chain-growth, polymer*) A polymer formed when monomers (usually containing  $C=C$ ) combine through an addition reaction.

**addition reaction** A type of organic reaction in which atoms linked by a multiple bond become bonded to more atoms.

**adduct** The product of a Lewis acid-base reaction, a species that contains a new covalent bond.

**adenosine triphosphate (ATP)** A high-energy molecule that serves most commonly as a store and source of energy in organisms.

**alcohol** An organic compound (ending, *-ol*) that contains a

**aldehyde** An organic compound (ending, *-al*) that contains the carbonyl functional group ( $C=\ddot{O}$ ) in which the carbonyl C is also bonded to H.

**alkane** A hydrocarbon that contains only single bonds (general formula,  $C_nH_{2n+2}$ ).

**alkene** A hydrocarbon that contains at least one  $C=C$  bond (general formula,  $C_nH_{2n}$ ).

**alkyl group** A saturated hydrocarbon chain with one bond available.

**alkyl halide** (See *haloalkane*.)

**alkyne** A hydrocarbon that contains at least one  $C\equiv C$  bond (general formula,  $C_nH_{2n-2}$ ).

**allotrope** One of two or more crystalline or molecular forms of an element. In general, one allotrope is more stable than another at a particular pressure and temperature.

**alloy** A mixture with metallic properties that consists of solid phases of two or more pure elements, a solid-solid solution, or distinct intermediate phases.

**alpha ( $\alpha$ ) decay** A radioactive process in which an alpha particle is emitted from a nucleus.

**alpha particle ( $\alpha$ ,  ${}^4_2\alpha$ , or  ${}^4_2\text{He}^{2+}$ )** A positively charged particle, identical to a helium-4 nucleus, that is one of the common types of radioactive emissions.

**amide** An organic compound that contains the  $\begin{array}{c} \text{:O:} \\ || \\ -C-\ddot{N}- \\ | \end{array}$  functional group.

**amine** An organic compound (general formula,  $\begin{array}{c} | \\ -C-\ddot{N}- \\ | \end{array}$ ) derived structurally by replacing one or more H atoms of ammonia with organic groups; a weak organic base.

**amino acid** An organic compound [general formula,  $H_2N-CH(R)-COOH$ ] with at least one carboxyl and one amine group on the same molecule; the monomer unit of a protein.

**amorphous solid** A solid that has a poorly defined shape because its particles do not have an orderly arrangement throughout a sample.

**ampere (A)** The SI unit of electric current; 1 ampere of current results when 1 coulomb of charge flows through a conductor in 1 second.

**amphoteric** Able to act as either an acid or a base.

**amplitude** The height of the crest (or depth of the trough) of a wave; related to the intensity of the energy (brightness of the light).

**angular momentum quantum number ( $l$ )** An integer from 0 to  $n - 1$  that is related to the shape of an atomic orbital.

**anion** A negatively charged ion.

**anode** The electrode at which oxidation occurs in an electrochemical cell. Electrons are given up by the reducing agent and leave the cell at the anode.

**antibonding MO** A molecular orbital formed when wave functions are subtracted from each other, which decreases electron density between the nuclei and leaves a node. Electrons occupying such an orbital destabilize the molecule.

**apatite** A compound of general formula  $Ca_5(PO_4)_3X$ , where X is generally F, Cl, or OH; a source of phosphorus.

**aqueous solution** A solution in which water is the solvent.

**aromatic hydrocarbon** A compound of C and H with one or more rings of C atoms (often drawn with alternating C—C and C=C bonds), in which there is extensive delocalization of  $\pi$  electrons.

**Arrhenius acid-base definition** A model of acid-base behavior in which an acid is a substance that has H in its formula and dissociates in water to yield  $\text{H}_3\text{O}^+$ , and a base is a substance that has OH in its formula and produces  $\text{OH}^-$  in water.

**Arrhenius equation** An equation that expresses the exponential relationship between temperature and the rate constant:  $k = Ae^{-E_a/RT}$ .

**atmosphere** The mixture of gases that extends from a planet's surface and eventually merges with outer space; the gaseous region of Earth's crust. (For the unit, see *standard atmosphere*.)

**atom** The smallest unit of an element that retains the chemical nature of the element. A neutral, spherical entity composed of a positively charged central nucleus surrounded by one or more negatively charged electrons.

**atomic mass** (also *atomic weight*) The average of the masses of the naturally occurring isotopes of an element weighted according to their abundances.

**atomic mass unit (amu)** (also *dalton, Da*) A mass exactly equal to  $\frac{1}{12}$  the mass of a carbon-12 atom.

**atomic number (Z)** The unique number of protons in the nucleus of each atom of an element (equal to the number of electrons in the neutral atom). An integer that expresses the positive charge of a nucleus or subatomic particle in multiples of the electronic charge.

**atomic orbital** A wave function for an electron that describes the region of space in which there is a high probability of finding the electron.

**atomic size** A measure of how closely one atom lies next to another, atomic size is determined from the distances between nuclei of adjacent atoms. (See also *metallic radius* and *covalent radius*.)

**atomic solid** A solid consisting of individual atoms held together by dispersion forces; the frozen noble gases are the only examples.

**atomic symbol** (also *element symbol*) A one- or two-letter abbreviation for the English, Latin, or Greek name of an element.

**aufbau principle** The conceptual approach for building up atoms by adding one proton at a time to the nucleus and one electron to the lowest energy sublevel that is available, to obtain the ground-state electron configurations of the elements.

**autoionization** (also *self-ionization*) A reaction in which two molecules of a substance react to give ions. The most important example is for water:  $2\text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{OH}^-(aq)$

**average rate** The change in concentration of reactants (or products) divided by a finite time period.

**Avogadro's law** The gas law stating that, at fixed temperature and pressure, equal volumes of any ideal gas contain equal numbers of particles, and, therefore, the volume of a gas is directly proportional to its amount (mol):  $V \propto n$ .

**Avogadro's number** A number ( $6.022 \times 10^{23}$  to four significant figures) equal to the number of atoms in exactly 12 g of carbon-12; the number of atoms, molecules, or formula units in one mole of an element or compound.

**axial group** An atom (or group) that lies above or below the trigonal plane of a trigonal bipyramidal molecule, or a similar structural feature in a molecule.

## B

**background radiation** Natural ionizing radiation, the most important form of which is cosmic radiation.

**balancing coefficient** (also *stoichiometric coefficient*) A numerical multiplier of all the atoms in the formula immediately following it in a balanced chemical equation.

**band of stability** The band of stable nuclides that appears on a plot of number of neutrons vs. number of protons for all nuclides.

**band theory** An extension of molecular orbital (MO) theory that explains many properties of metals and other solids, in particular, the differences in conductivity of metals, metalloids, and nonmetals.

**barometer** A device used to measure atmospheric pressure. Most commonly, a tube open at one end, which is filled with mercury and inverted into a dish of mercury.

**base** In common laboratory terms, any species that produces  $\text{OH}^-$  ions when dissolved in water. (See also *Arrhenius*, *Brønsted-Lowry*, and *Lewis acid-base* definitions.)

**base pair** Two complementary mononucleotide bases that are H bonded to each other; guanine (G) always pairs with cytosine (C), and adenine (A) always pairs with thymine (T) (or uracil, U, in RNA).

**base unit** (also *fundamental unit*) A unit that defines the standard for one of the seven physical quantities in the International System of Units (SI).

**base-dissociation (base-ionization) constant ( $K_b$ )** An equilibrium constant for the reaction of a base (B) with  $\text{H}_2\text{O}$  to yield the conjugate acid ( $\text{BH}^+$ ) and  $\text{OH}^-$ :

$$K_b = \frac{[\text{BH}^+][\text{OH}^-]}{[\text{B}]}$$

**basic-oxygen process** The method used to convert pig iron to steel, in which  $\text{O}_2$  is blown over and through molten pig iron to oxidize impurities and decrease the content of carbon.

**battery** A group of voltaic cells arranged in series; primary and secondary types are self-contained, but flow batteries are not.

**becquerel (Bq)** The SI unit of radioactivity; 1 Bq = 1 d/s (disintegration per second).

**bent shape** (also *V shape*) A molecular shape that arises when a central atom is bonded to two other atoms and has one or two lone pairs; occurs as the  $\text{AX}_2\text{E}$  shape class (bond angle  $< 120^\circ$ ) in the trigonal planar arrangement and as the  $\text{AX}_2\text{E}_2$  shape class (bond angle  $< 109.5^\circ$ ) in the tetrahedral arrangement.

**beta ( $\beta$ ) decay** A radioactive change that encompasses any of three specific processes:  $\beta^-$  decay,  $\beta^+$  emission, or  $e^-$  capture.

**beta particle ( $\beta$ ,  $\beta^-$ , or  ${}_{-1}^0\beta$ )** A negatively charged particle, identified as a high-speed electron, that is one of the common types of radioactive emissions.

**bimolecular reaction** An elementary reaction involving the collision of two reactant species.

**binary covalent compound** A compound that consists of atoms of two elements, typically nonmetals, in which bonding occurs primarily through electron sharing.

**binary ionic compound** A compound that consists of the oppositely charged ions of two elements.

**biomass conversion** The process of applying chemical and biological methods to convert plant or animal matter into fuels.

**biosphere** The living systems that inhabit Earth.

**blast furnace** A tower-shaped furnace made of brick material in which intense heat and blasts of air are used to convert iron ore and coke to iron metal and carbon dioxide.

**body-centered cubic unit cell** A unit cell in which a particle lies at each corner and in the center of a cube.

**boiling point (bp or  $T_b$ )** The temperature at which the vapor pressure inside bubbles forming in a liquid equals the external (atmospheric) pressure.

**boiling point elevation ( $\Delta T_b$ )** The increase in the boiling point of a solvent caused by the presence of dissolved solute.

**bond angle** The angle formed by the bonds joining the nuclei of two surrounding atoms to the nucleus of the central atom, which is at the vertex.

**bond energy (BE)** (also *bond enthalpy* or *bond strength*) The standard enthalpy change (always  $> 0$ ) accompanying the breakage of a given bond in 1 mol of gaseous molecules.

**bond length** The distance between the nuclei of two bonded atoms.

**bond order** The number of electron pairs shared by two bonded atoms.

**bonding MO** A molecular orbital formed when wave functions are added to each other, which increases electron density between the nuclei. Electrons occupying such an orbital stabilize the molecule.

**bonding pair** (also *shared pair*) An electron pair shared by two nuclei; the mutual attraction between the nuclei and the electron pair forms a covalent bond.

**Born-Haber cycle** A series of hypothetical steps and their enthalpy changes that converts elements to an ionic compound; it is used to calculate the lattice energy.

**Boyle's law** The gas law stating that, at constant temperature and amount of gas, the volume occupied by a gas is inversely proportional to the applied (external) pressure:  $V \propto 1/P$ .

**branch** A side chain appended to a polymer backbone or to the longest sequence of atoms in an organic compound.

**bridge bond** (also *three-center, two-electron bond*) A covalent bond in which three atoms are held together by two electrons.

**Brønsted-Lowry acid-base definition** A model of acid-base behavior based on proton transfer, in which an acid and a base are defined, respectively, as a species that donates a proton and one that accepts a proton.

**buffer** (See *acid-base buffer*.)

**buffer capacity** A measure of the ability of a buffer to resist a change in pH; related to the total concentrations and relative proportions of buffer components.

**buffer range** The pH range over which a buffer acts effectively.

## C

**calibration** The process of correcting for systematic error of a measuring device by comparing it to a known standard.

**calorie (cal)** A unit of energy defined as exactly 4.184 joules; originally defined as the heat needed to raise the temperature of 1 g of water 1°C (from 14.5°C to 15.5°C).

**calorimeter** A device used to measure the heat released or absorbed by a physical or chemical process taking place within it.

**capillarity** (or *capillary action*) The rising of a liquid through a narrow space against the pull of gravity.

**carbon steel** The steel that is produced by the basic-oxygen process, contains about 1% to 1.5% C and other impurities, and is alloyed with metals that prevent corrosion and increase strength or flexibility.

**carbonyl group** The C=O grouping of atoms.

**carboxylic acid** An organic compound (ending, *-oic acid*) that

contains the  $\begin{array}{c} \text{:O:} \\ \parallel \\ \text{—C—}\ddot{\text{O}}\text{H} \end{array}$  group.

**catalyst** A substance or mixture that increases the rate of a reaction without being used up in the process.

**catenation** The process by which atoms of an element bond to each other in chains; most common with carbon in organic compounds but also occurs with boron, silicon, sulfur, and several other elements.

**cathode** The electrode at which reduction occurs in an electrochemical cell. Electrons enter the cell and are acquired by the oxidizing agent at the cathode.

**cathode ray** The ray of light emitted by the cathode (negative electrode) in a gas discharge tube; travels in a straight line, unless deflected by magnetic or electric fields.

**cation** A positively charged ion.

**cell potential ( $E_{\text{cell}}$ )** (also *electromotive force*, or *emf*; *cell voltage*) The difference in electrical potential between the two electrodes of an electrochemical cell.

**Celsius scale** (formerly *centigrade scale*) A temperature scale in which the freezing and boiling points of water are defined as 0°C and 100°C, respectively.

**ceramic** A nonmetallic, nonpolymeric solid that is hardened by heating it to high temperatures and, in most cases, consists of silicate microcrystals suspended in a glassy cementing medium.

**chain reaction** In nuclear fission, a self-sustaining process in which neutrons released by splitting of one nucleus cause other nuclei to split, which releases more neutrons, and so on.

**change in enthalpy ( $\Delta H$ )** The change in the system's internal energy plus the product of the constant pressure and the change in volume:  $\Delta H = \Delta E + P\Delta V$ ; alternatively, the heat lost or gained at constant pressure:  $\Delta H = q_p$ .

**charge density** The ratio of the charge of an ion to its volume.

**Charles's law** The gas law stating that at constant pressure, the volume occupied by a fixed amount of gas is directly proportional to its absolute temperature:  $V \propto T$ .

**chelate** A complex ion in which the metal ion is bonded to a bidentate or polydentate ligand.

**chemical bond** The force that holds two atoms together in a molecule (or formula unit).

**chemical change** (also *chemical reaction*) A change in which one or more substances are converted into one or more substances with different composition and properties.

**chemical equation** A statement that uses chemical formulas to express the identities and quantities of the substances involved in a chemical or physical change.

**chemical formula** A notation of atomic symbols and numerical subscripts that shows the type and number of each atom in a molecule or formula unit of a substance.

**chemical kinetics** The study of the rates of reactions and the factors that affect them.

**chemical property** A characteristic of a substance that appears as it interacts with, or transforms into, other substances.

**chemical reaction** (See *chemical change*.)

**chemistry** The scientific study of matter and its properties, the changes it undergoes, and the energy associated with those changes.

**chiral molecule** One that is not superimposable on its mirror image; an optically active molecule. In organic compounds, a chiral molecule typically contains a C atom bonded to four different groups (an asymmetric carbon).

**chlor-alkali process** An industrial method that electrolyzes concentrated aqueous NaCl and produces  $\text{Cl}_2$ ,  $\text{H}_2$ , and NaOH.

**chromatography** A separation technique in which a mixture is dissolved in a fluid (gas or liquid), and the components are separated through differences in adsorption to (or solubility in) a solid surface (or viscous liquid).

**cis-trans isomers** (See *geometric isomers*.)

**Clausius-Clapeyron equation** An equation that expresses the linear relationship between vapor pressure  $P$  of a liquid and temperature  $T$ ; in two-point form, it is

$$\ln \frac{P_2}{P_1} = \frac{-\Delta H_{\text{vap}}}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right)$$

**coal gasification** An industrial process for altering the large molecules in coal to sulfur-free gaseous fuels.

**colligative property** A property of a solution that depends on the number, not the identity, of solute particles. (See also *boiling point elevation*, *freezing point depression*, *osmotic pressure*, and *vapor pressure lowering*.)

**collision frequency** The average number of collisions per second that a particle undergoes.

**collision theory** A model that explains reaction rate as based on the number, energy, and orientation of colliding particles.

**colloid** A heterogeneous mixture in which a dispersed (solute-like) substance is distributed throughout a dispersive (solvent-like) substance.

**combustion** The process of burning in air, often with release of heat and light.

**combustion analysis** A method for determining the formula of a compound from the amounts of its combustion products; used commonly for organic compounds.

**common-ion effect** The shift in the position of an ionic equilibrium away from an ion involved in the process that is caused by the addition or presence of that ion.

**complex** (See *coordination compound*.)

**complex ion** An ion consisting of a central metal ion covalently bonded to two or more anions or molecules, called ligands.

**composition** The types and amounts of simpler substances that make up a sample of matter.

**compound** A substance composed of two or more elements that are chemically combined in fixed proportions.

**concentration** A measure of the quantity of solute dissolved in a given quantity of solution (or of solvent).

**concentration cell** A voltaic cell in which both compartments contain the same components but at different concentrations.

**condensation** The process of a gas changing into a liquid.

**condensation polymer** A polymer formed from monomers with two functional groups that are linked together in a dehydration-condensation reaction.

**conduction band** In band theory, the empty, higher energy portion of the band of molecular orbitals into which electrons move when conducting heat and electricity.

**conductor** A substance (usually a metal) that conducts an electric current well.

**conjugate acid-base pair** Two species related to each other through the gain or loss of a proton; the acid has one more proton than its conjugate base.

**constitutional isomers** (also *structural isomers*) Compounds with the same molecular formula but different arrangements of atoms.

**contact process** An industrial process for the manufacture of sulfuric acid based on the catalyzed oxidation of  $\text{SO}_2$ .

**controlled experiment** An experiment that measures the effect of one variable at a time by keeping other variables constant.

**conversion factor** A ratio of equivalent quantities that is equal to 1 and used to express a quantity in different units.

**coordinate covalent bond** A covalent bond formed when one atom donates both electrons to provide the shared pair; once formed, this bond is identical to any covalent single bond.

**coordination compound** (also *complex*) A substance containing at least one complex ion and counter ion(s).

**coordination isomers** Two or more coordination compounds with the same composition in which the complex ions have different ligand arrangements.

**coordination number** In a crystal, the number of nearest neighbors surrounding a particle. In a complex ion, the number of ligand atoms bonded to the central metal ion.

**copolymer** A polymer that consists of two or more types of monomer.

**core** The dense, innermost region of Earth.

**core electrons** (See *inner electrons*.)

**corrosion** The natural redox process that results in unwanted oxidation of a metal.

**coulomb (C)** The SI unit of electric charge. One coulomb is the charge of  $6.242 \times 10^{18}$  electrons; one electron possesses a charge of  $1.602 \times 10^{-19}$  C.

**Coulomb's law** A law stating that the electrostatic energy between particles A and B is directly proportional to the product of their charges and inversely proportional to the distance between them:

$$\text{electrostatic energy} \propto \frac{\text{charge A} \times \text{charge B}}{\text{distance}}$$

**counter ion** A simple ion associated with a complex ion in a coordination compound.

**coupling of reactions** The pairing of reactions of which one releases enough free energy for the other to occur.

**covalent bond** A type of bond in which atoms are bonded through the sharing of electrons; the mutual attraction of the nuclei and an electron pair that holds atoms together in a molecule.

**covalent bonding** The idealized bonding type that is based on localized electron-pair sharing between two atoms with little difference in their tendencies to lose or gain electrons (most commonly nonmetals).

**covalent compound** A compound that consists of atoms bonded together by shared electron pairs.

**covalent radius** One-half the shortest distance between nuclei of identical covalently bonded atoms.

**critical mass** The minimum mass of a fissionable substance needed to achieve a chain reaction.

**critical point** The point on a phase diagram above which the vapor cannot be condensed to a liquid; the end of the liquid-gas curve.

**crosslink** A branch that covalently joins one polymer chain to another.

**crust** The thin, light, heterogeneous outer layer of Earth, which consists of gaseous, liquid, and solid regions.

**crystal defect** Any of a variety of disruptions in the regularity of a crystal structure.

**crystal field splitting energy ( $\Delta$ )** The difference in energy between two sets of metal-ion  $d$  orbitals that results from electrostatic interactions with the surrounding ligands.

**crystal field theory** A model that explains the color and magnetism of complex ions and their coordination compounds based on the effects of ligands on metal-ion  $d$ -orbital energies.

**crystalline solid** Solid with a well-defined shape because of the orderly arrangement of the atoms, molecules, or ions.

**crystallization** A technique used to separate and purify the components of a mixture through differences in solubility, resulting in a component coming out of solution as crystals.

**cubic closest packing** A crystal structure based on the face-centered cubic unit cell in which the layers have an *abcabc...* pattern.

**cubic meter (m<sup>3</sup>)** The derived SI unit of volume.

**curie (Ci)** The most common unit of radioactivity, originally defined as the number of nuclei disintegrating each second in 1 g of radium-226; now a fixed quantity, 1 Ci = 3.70×10<sup>10</sup> d/s (disintegrations per second).

**cyclic hydrocarbon** A hydrocarbon with one or more rings in its structure.

## D

**d orbital** An atomic orbital with *l* = 2.

**dalton (Da)** A unit of mass identical to *atomic mass unit (amu)*.

**Dalton's law of partial pressures** A gas law stating that, in a mixture of unreacting gases, the total pressure is the sum of the partial pressures of the individual gases:  $P_{\text{total}} = P_1 + P_2 + P_3 + \dots$

**data** Pieces of quantitative information obtained by observation.

**de Broglie wavelength** The wavelength of a moving particle obtained from the de Broglie equation:  $\lambda = h/mv$ .

**decay constant** The rate constant *k* for radioactive decay.

**decay series** (also *disintegration series*) The succession of steps a parent nuclide undergoes as it decays into a stable daughter nuclide.

**degree of polymerization (n)** The number of repeat units in a polymer chain.

**dehydration-condensation reaction** A reaction in which an H<sub>2</sub>O molecule is lost for every pair of groups that join.

**delocalization** (See *electron-pair delocalization*.)

**density (d)** An intensive physical property of a substance at a given temperature and pressure, defined as the ratio of the mass to the volume:  $d = m/V$ .

**deposition** The process of changing directly from a gas to a solid.

**derived unit** Any of various combinations of the seven SI base units.

**desalination** A process used to remove large amounts of ions from seawater, usually by reverse osmosis.

**deuterons** Nuclei of the stable hydrogen isotope deuterium, <sup>2</sup>H.

**diagonal relationship** Physical and chemical similarities between a Period 2 element and one located diagonally down and to the right in Period 3.

**diamagnetism** The tendency of a species not to be attracted (or to be slightly repelled) by a magnetic field as a result of its electrons being paired.

**diastereomers** (See *geometric isomers*.)

**differentiation** The geochemical process by which regions in Earth were formed based on differences in composition and density.

**diffraction** The phenomenon in which a wave striking the edge of an object bends around it. A wave passing through a slit as wide as its wavelength forms a circular wave.

**diffusion** The movement of one fluid through another.

**dimensional analysis** (also *factor-label method*) A calculation method in which arithmetic steps are accompanied by canceling units that represent physical dimensions.

**dipole moment (μ)** A measure of molecular polarity; the magnitude of the partial charges on the ends of a molecule (in coulombs) times the distance between them (in meters).

**dipole-dipole force** The intermolecular attraction between oppositely charged poles of nearby polar molecules.

**dipole-induced dipole force** The intermolecular attraction between a polar molecule and the oppositely charged pole it induces in a nearby molecule.

**disaccharide** An organic compound formed by a dehydration-condensation reaction between two simple sugars (monosaccharides).

**disintegration series** (See *decay series*.)

**dispersion force** (also *London force*) The intermolecular attraction between all particles as a result of instantaneous polarizations of their electron clouds; the intermolecular force primarily responsible for the condensed states of nonpolar substances.

**disproportionation reaction** A redox reaction in which one substance acts as both the oxidizing and reducing agents.

**distillation** A separation technique in which a more volatile component of a mixture vaporizes and condenses separately from the less volatile components.

**donor atom** An atom that donates a lone pair of electrons to form a covalent bond, usually from ligand to metal ion in a complex ion.

**doping** Adding small amounts of other elements into the crystal structure of a semiconductor to enhance a specific property, usually conductivity.

**double bond** A covalent bond that consists of two bonding pairs; two atoms sharing four electrons in the form of one  $\sigma$  and one  $\pi$  bond.

**double helix** The two intertwined polynucleotide strands held together by H bonds that form the structure of DNA (deoxyribonucleic acid).

**Downs cell** An industrial apparatus that electrolyzes molten NaCl to produce sodium and chlorine.

**dynamic equilibrium** The condition at which the forward and reverse reactions are taking place at the same rate, so there is no net change in the amounts of reactants or products.

## E

**effective collision** A collision in which the particles meet with sufficient energy and an orientation that allows them to react.

**effective nuclear charge (Z<sub>eff</sub>)** The nuclear charge an electron actually experiences as a result of shielding effects due to the presence of other electrons.

**effusion** The process by which a gas escapes from its container through a tiny hole into an evacuated space.

**e<sub>g</sub> orbitals** The set of orbitals (composed of  $d_{x^2-y^2}$  and  $d_{z^2}$ ) that results when the energies of the metal-ion *d* orbitals are split by a ligand field. This set is higher in energy than the other (*t<sub>2g</sub>*) set in an octahedral field of ligands and lower in energy in a tetrahedral field.

**elastomer** A polymeric material that can be stretched and springs back to its original shape when released.

**electrochemical cell** A system that incorporates a redox reaction to produce or use electrical energy.

**electrochemistry** The study of the relationship between chemical change and electrical work.

**electrode** The part of an electrochemical cell that conducts the electricity between the cell and the surroundings.

**electrolysis** The nonspontaneous lysing (splitting) of a substance, often to its component elements, by the input of electrical energy.

**electrolyte** A substance that conducts a current when it dissolves in water. A mixture of ions, in which the electrodes of an electrochemical cell are immersed, that conducts a current.

**electrolytic cell** An electrochemical system that uses electrical energy to drive a nonspontaneous chemical reaction ( $\Delta G > 0$ ).

**electromagnetic radiation** (also *electromagnetic energy* or *radiant energy*) Oscillating, perpendicular electric and magnetic fields moving simultaneously through space as waves and manifested as visible light, x-rays, microwaves, radio waves, and so on.

**electromagnetic spectrum** The continuum of radiant energy arranged in order of increasing wavelength.

**electromotive force (emf)** (See *cell potential*.)

**electron ( $e^-$ ) capture (EC)** A type of radioactive decay in which a nucleus draws in an orbital electron, usually one from the lowest energy level, and releases energy.

**electron ( $e^-$ )** A subatomic particle that possesses a unit negative charge ( $-1.60218 \times 10^{-19}$  C) and occupies the space around the atomic nucleus.

**electron affinity (EA)** The energy change (in kJ) accompanying the addition of 1 mol of electrons to 1 mol of gaseous atoms or ions.

**electron cloud depiction** An imaginary representation of an electron's rapidly changing position around the nucleus over time.

**electron configuration** The distribution of electrons within the levels and sublevels of the atoms of an element; also the notation for such a distribution.

**electron deficient** Referring to a bonded atom, such as Be or B, that has fewer than eight valence electrons.

**electron density diagram** (also *electron probability density diagram*) The pictorial representation for a given energy sublevel of the quantity  $\psi^2$  (the probability density of the electron lying within a particular tiny volume) as a function of  $r$  (distance from the nucleus).

**electron volt (eV)** The energy (in joules, J) that an electron acquires when it moves through a potential difference of 1 volt;  $1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}$ .

**electron-pair delocalization** (also *delocalization*) The process by which electron density is spread over several atoms rather than remaining between two.

**electron-sea model** A qualitative description of metallic bonding proposing that metal atoms pool their valence electrons in a delocalized "sea" of electrons in which the metal ions (nuclei and core electrons) are submerged in an orderly array.

**electronegativity (EN)** The relative ability of a bonded atom to attract shared electrons.

**electronegativity difference ( $\Delta \text{EN}$ )** The difference in electronegativities between two bonded atoms.

**electrorefining** An industrial, electrolytic purification process in which a sample of impure metal acts as the anode and a sample of the pure metal acts as the cathode.

**element** The simplest type of substance with unique physical and chemical properties. An element consists of only one kind of atom, so it cannot be broken down into simpler substances.

**element symbol** (See *atomic symbol*.)

**elementary reaction** (also *elementary step*) A simple reaction that describes a single molecular event in a proposed reaction mechanism.

**elimination reaction** A type of organic reaction in which C atoms are bonded to fewer atoms in the product than in the reactant, which creates a multiple bond between the C atoms.

**emission spectrum** The line spectrum produced when excited atoms return to lower energy levels and emit photons characteristic of the element.

**empirical formula** A chemical formula that shows the lowest relative number of atoms of each element in a compound.

**enantiomers** (See *optical isomers*.)

**end point** The point in a titration at which the indicator changes color permanently.

**endothermic process** A process that occurs with an absorption of heat from the surroundings and therefore an increase in the enthalpy of the system ( $\Delta H > 0$ ).

**energy** The ability to do work, that is, to move matter. [See also *kinetic energy* ( $E_k$ ) and *potential energy* ( $E_p$ ).]

**enthalpy ( $H$ )** A thermodynamic quantity that is equal to the system's internal energy plus the product of the pressure and volume.

**enthalpy diagram** A graphic depiction of the enthalpy change of a system.

**Enthalpy of formation ( $\Delta H_f^\circ$ )** (also *heat of formation*) The enthalpy change occurring when 1 mol of a compound forms from its elements. When all components are in their standard states, this is called the standard enthalpy of formation ( $\Delta H_f^\circ$ ).

**Enthalpy of fusion** (See *heat of fusion*.)

**Enthalpy of hydration** (See *heat of hydration*.)

**Enthalpy of reaction ( $\Delta H_{\text{rxn}}$ )** (also *heat of reaction*) The enthalpy change that occurs during a reaction. When all components are in their standard states, this is called the *standard enthalpy of reaction* ( $\Delta H_{\text{rxn}}^\circ$ ).

**Enthalpy of solution** (See *heat of solution*.)

**Enthalpy of sublimation** (See *heat of sublimation*.)

**Enthalpy of vaporization** (See *heat of vaporization*.)

**entropy ( $S$ )** A thermodynamic quantity related to the number of ways the energy of a system can be dispersed through the motions of its particles.

**environmental cycle** The physical, chemical, and biological paths through which the atoms of an element move within Earth's crust.

**enzyme** A biological macromolecule (usually a protein) that acts as a catalyst.

**enzyme-substrate complex (ES)** The intermediate in an enzyme-catalyzed reaction, which consists of enzyme and substrate(s) and whose concentration determines the rate of product formation.

**equatorial group** An atom (or group) that lies in the trigonal plane of a trigonal bipyramidal molecule, or a similar structural feature in a molecule.

**equilibrium constant ( $K$ )** The value obtained when equilibrium concentrations are substituted into the reaction quotient.

**equilibrium vapor pressure** (See *vapor pressure*.)

**equivalence point** The point in a titration when the number of moles of the added species is stoichiometrically equivalent to the original number of moles of the other species.

**ester** An organic compound that contains the  group.

**exact number** A quantity, usually obtained by counting or based on a unit definition, that has no uncertainty associated with it and, therefore, contains as many significant figures as a calculation requires.

**exchange reaction** (See *metathesis reaction*.)

**excited state** Any electron configuration of an atom (or ion or molecule) other than the lowest energy (ground) state.

**exclusion principle** A principle developed by Wolfgang Pauli stating that no two electrons in an atom can have the same set of four quantum numbers. The principle arises from the fact that an orbital has a maximum occupancy of two electrons and their spins are paired.

**exothermic process** A process that occurs with a release of heat to the surroundings and therefore a decrease in the enthalpy of the system ( $\Delta H < 0$ ).

**expanded valence shell** A valence level that can accommodate more than eight electrons by using available  $d$  orbitals; occurs only with central nonmetal atoms from Period 3 or higher.

**experiment** A set of procedural steps that tests a hypothesis.

**extensive property** A property, such as mass, that depends on the quantity of substance present.

## F

**f orbital** An atomic orbital with  $l = 3$ .

**face-centered cubic unit cell** A unit cell in which a particle occurs at each corner and in the center of each face of a cube.

**Faraday constant ( $F$ )** The physical constant representing the charge of 1 mol of electrons:  $F = 96,485 \text{ C/mol e}^-$ .

**fatty acid** A carboxylic acid that has a long hydrocarbon chain and is derived from a natural source.

**filtration** A method of separating the components of a mixture on the basis of differences in particle size.

**first law of thermodynamics** (See *law of conservation of energy*.)

**fission** The process by which a heavier nucleus splits into two much lighter nuclei, with the release of a large quantity of energy.

**fixation** A chemical or biochemical process that converts a gaseous substance in the environment into a condensed form that can be used by organisms.

**flame test** A procedure for identifying the presence of metal ions in which a granule of a compound or a drop of its solution is placed in a flame to observe a characteristic color.

**flotation** A metallurgical process in which an oil-detergent mixture is stirred with pulverized ore in water to create a slurry, followed by rapid mixing of the slurry with air to produce an oily, mineral-rich froth that floats, separating the mineral from the gangue.

**formal charge** The hypothetical charge on an atom in a molecule or ion, equal to the number of valence electrons minus the sum of all the unshared and half the shared valence electrons.

**formation constant ( $K_f$ )** An equilibrium constant for the formation of a complex ion from the hydrated metal ion and ligands.

**formation equation** An equation in which 1 mole of a compound forms from its elements.

**formula mass** The sum (in amu) of the atomic masses of a formula unit of a (usually ionic) compound.

**formula unit** The chemical unit of a compound that contains the relative numbers of the types of atoms or ions expressed in the chemical formula.

**fossil fuel** Any fuel, including coal, petroleum, and natural gas, derived from the products of the decay of dead organisms.

**fraction by mass** (also *mass fraction*) The portion of a compound's mass contributed by an element; the mass of an element in a compound divided by the mass of the compound.

**fractional distillation** A physical process involving numerous vaporization-condensation steps used to separate two or more volatile components.

**free energy ( $G$ )** A thermodynamic quantity that is the difference between the system's enthalpy and the product of the absolute temperature and the system's entropy:  $G = H - TS$ .

**free energy change ( $\Delta G$ )** The change in free energy that occurs during a reaction.

**free radical** A molecular or atomic species with one or more unpaired electrons, which typically make it very reactive.

**freezing** The process of cooling a liquid until it solidifies.

**freezing point depression ( $\Delta T_f$ )** The lowering of the freezing point of a solvent caused by the presence of dissolved solute particles.

**frequency ( $\nu$ )** The number of complete waves, or cycles, that pass a given point per second, expressed in units of 1/second, or  $\text{s}^{-1}$  [also called *hertz* (Hz)]; related inversely to wavelength.

**frequency factor ( $A$ )** The product of the collision frequency  $Z$  and an orientation probability factor  $p$  that is specific for a reaction.

**fuel cell** (also *flow battery*) A battery that is not self-contained and in which electricity is generated by the controlled oxidation of a fuel.

**functional group** A specific combination of bonded atoms, typically containing a carbon-carbon multiple bond and/or a carbon-heteroatom bond, that reacts in a characteristic way no matter what molecule it occurs in.

**fundamental unit** (See *base unit*.)

**fusion** (See *melting*.)

**fusion (nuclear)** The process by which light nuclei combine to form a heavier nucleus with the release of energy.

## G

**galvanic cell** (See *voltaic cell*.)

**gamma emission** The type of radioactive decay in which gamma rays are emitted from an excited nucleus.

**gamma ray ( $\gamma$ )** A very high-energy photon.

**gangue** In an ore, the debris, such as sand, rock, and clay, attached to the mineral.

**gas** One of the three states of matter. A gas fills its container regardless of the shape because its particles are far apart.

**Geiger-Müller counter** An ionization counter that detects radioactive emissions through their ionization of gas atoms within the instrument.

**genetic code** The set of three-base sequences that is translated into specific amino acids during the process of protein synthesis.

**geometric isomers** (also *cis-trans isomers* or *diastereomers*) Stereoisomers in which the molecules have the same connections between atoms but differ in the spatial arrangements of the atoms. The *cis* isomer has identical groups on the same side of a double bond (or of a central metal atom); the *trans* isomer has them on opposite sides.

**Graham's law of effusion** A gas law stating that the rate of effusion of a gas is inversely proportional to the square root of its density (or molar mass):

$$\text{rate} \propto \frac{1}{\sqrt{M}}$$

**gray (Gy)** The SI unit of absorbed radiation dose;  $1 \text{ Gy} = 1 \text{ J/kg tissue}$ .

**green chemistry** Field that is focused on developing methods to synthesize compounds efficiently and reduce or prevent the release of harmful products into the environment.

**ground state** The electron configuration of an atom (or ion or molecule) that is lowest in energy.

**group** A vertical column in the periodic table; elements in a group usually have the same outer electron configuration and, thus, similar chemical behavior.

## H

**H bond** (See *hydrogen bond*.)

**Haber process** An industrial process used to form ammonia from its elements.

**half-cell** A portion of an electrochemical cell in which a half-reaction takes place.

**half-life ( $t_{1/2}$ )** In chemical processes, the time required for the reactant concentration to reach half of its initial value. In nuclear processes, the time required for half the initial number of nuclei in a sample to decay.

**half-reaction method** A method of balancing redox reactions by treating the oxidation and reduction half-reactions separately.

**haloalkane** (also *alkyl halide*) A hydrocarbon with one or more halogen atoms (X) in place of H; contains a  $\text{—}\overset{\text{H}}{\underset{\text{H}}{\text{C}}}\text{—}\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{X}}}$  group.

**hard water** Water that contains large amounts of divalent cations, especially  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ .

**heat ( $q$ )** (also *thermal energy*) The energy transferred between objects because of a difference in their temperatures only.

**heat capacity ( $C$ )** The quantity of heat required to change the temperature of an object by 1 K.

**heat of formation** (See *enthalpy of formation*.)

**heat of fusion ( $\Delta H_{\text{fus}}^{\circ}$ )** (also *enthalpy of fusion*) The enthalpy change occurring when 1 mol of a solid substance melts; designated ( $\Delta H_{\text{fus}}^{\circ}$ ) at the standard state.

**heat of hydration ( $\Delta H_{\text{hydr}}$ )** (also *enthalpy of hydration*) The enthalpy change occurring when 1 mol of a gaseous species (often an ion) is hydrated. The sum of the enthalpies from separating water molecules and mixing the gaseous species with them; designated  $\Delta H_{\text{hydr}}^{\circ}$  at the standard state.

**heat of reaction ( $\Delta H_{\text{rxn}}$ )** (See *enthalpy of reaction*.)

**heat of solution ( $\Delta H_{\text{soln}}$ )** (also *enthalpy of hydration*) The enthalpy change occurring when a solution forms from solute and solvent. The sum of the enthalpies from separating solute and solvent substances and mixing them; designated ( $\Delta H_{\text{soln}}^{\circ}$ ) at the standard state.

**heat of sublimation ( $\Delta H_{\text{subl}}^{\circ}$ )** (also *enthalpy of sublimation*) The enthalpy change occurring when 1 mol of a solid substance changes directly to a gas. The sum of the heats of fusion and vaporization; designated at the standard state.

**heat of vaporization ( $\Delta H_{\text{vap}}^{\circ}$ )** (also *enthalpy of vaporization*) The enthalpy change occurring when 1 mol of a liquid substance vaporizes; designated ( $\Delta H_{\text{vap}}^{\circ}$ ) at the standard state.

**heating-cooling curve** A plot of temperature vs. time for a sample when heat is absorbed or released at a constant rate.

**Henderson-Hasselbalch equation** An equation for calculating the pH of a buffer system:

$$\text{pH} = \text{p}K_{\text{a}} + \log \left( \frac{[\text{base}]}{[\text{acid}]} \right)$$

**Henry's law** A law stating that the solubility of a gas in a liquid is directly proportional to the partial pressure of the gas above the liquid:  $S_{\text{gas}} = k_{\text{H}} \times P_{\text{gas}}$ .

**Hess's law** A law stating that the enthalpy change of an overall process is the sum of the enthalpy changes of the individual steps.

**heteroatom** Any atom in an organic compound other than C or H.

**heterogeneous catalyst** A catalyst that occurs in a different phase from the reactants, usually a solid interacting with gaseous or liquid reactants.

**heterogeneous mixture** A mixture that has one or more visible boundaries among its components.

**hexagonal closest packing** A crystal structure based on the hexagonal unit cell in which the layers have an *abab...* pattern.

**high-spin complex** Complex ion that has the same number of unpaired electrons as in the isolated metal ion; contains weak-field ligands.

**homogeneous catalyst** A catalyst (gas, liquid, or soluble solid) that exists in the same phase as the reactants.

**homogeneous mixture** (also *solution*) A mixture that has no visible boundaries among its components.

**homologous series** A series of organic compounds in which each member differs from the next by a  $-\text{CH}_2-$  (methylene) group.

**homonuclear diatomic molecule** A molecule composed of two identical atoms.

**Hund's rule** A principle stating that when orbitals of equal energy are available, the electron configuration of lowest energy has the maximum number of unpaired electrons with parallel spins.

**hybrid orbital** An atomic orbital postulated to form during bonding by the mathematical mixing of specific combinations of non-equivalent orbitals in a given atom.

**hybridization** A postulated process of orbital mixing to form hybrid orbitals.

**hydrate** A compound in which a specific number of water molecules are associated with each formula unit.

**hydration** Solvation in water.

**hydration shell** The oriented cluster of water molecules that surrounds an ion in aqueous solution.

**hydrocarbon** An organic compound that contains only H and C atoms.

**hydrogen bond (H bond)** A type of dipole-dipole force that arises between molecules that have an H atom bonded to a small, highly electronegative atom with lone pairs, usually N, O, or F.

**hydrogenation** The addition of hydrogen to a carbon-carbon multiple bond to form a carbon-carbon single bond.

**hydrolysis** Cleaving a molecule by reaction with water; one part of the molecule bonds to water's  $-\text{OH}$  and the other to water's other H.

**hydronium ion ( $\text{H}_3\text{O}^+$ )** A proton covalently bonded to a water molecule.

**hydrosphere** The liquid region of Earth's crust.

**hypothesis** A testable proposal made to explain an observation. If inconsistent with experimental results, a hypothesis is revised or discarded.

**ideal gas** A hypothetical gas that exhibits linear relationships among volume, pressure, temperature, and amount (mol) at all conditions; approximated by simple gases at ordinary conditions.

**ideal gas law** (also *ideal gas equation*) An equation that expresses the relationships among volume, pressure, temperature, and amount (mol) of an ideal gas:  $PV = nRT$ .

**ideal solution** A solution that follows Raoult's law at any concentration.

**indicator** (See *acid-base indicator*.)

**induced-fit model** A model of enzyme action that pictures the binding of the substrate as inducing the active site to change its shape and become catalytically active.

**infrared (IR)** The region of the electromagnetic spectrum between the microwave and visible regions.

**infrared (IR) spectroscopy** An instrumental technique for determining the types of bonds in a covalent molecule by measuring the absorption of IR radiation.

**initial rate** The instantaneous rate at the moment the reactants are mixed, that is, at  $t = 0$ .

**inner electrons** (also *core electrons*) Electrons that fill all the energy levels of an atom except the valence level; electrons also present in atoms of the previous noble gas and any completed transition series.

**inner transition elements** The elements of the periodic table in which the seven inner *f* orbitals are being filled; the lanthanides and the actinides.

**instantaneous rate** The reaction rate at a particular time, given by the slope of a tangent to a plot of reactant concentration vs. time.

**insulator** A substance (usually a nonmetal) that does not conduct an electric current.

**integrated rate law** A mathematical expression for reactant concentration as a function of time.

**intensive property** A property, such as density, that does not depend on the quantity of substance present.

**interhalogen compound** A compound consisting entirely of halogens.

**intermolecular forces** (also *interparticle forces*) The attractive and repulsive forces among the particles—molecules, atoms, or ions—in a sample of matter.

**internal energy ( $E$ )** The sum of the kinetic and potential energies of all the particles in a system.

**ion** A charged particle that forms from an atom (or covalently bonded group of atoms) when it gains or loses one or more electrons.

**ion exchange** A process of softening water by exchanging one type of ion (usually  $\text{Ca}^{2+}$ ) for another (usually  $\text{Na}^+$ ) by binding the ions on a specially designed resin.

**ion pair** A gaseous ionic molecule, formed when an ionic compound vaporizes.

**ion-dipole force** The intermolecular attractive force between an ion and a polar molecule (dipole).

**ion-product constant for water ( $K_w$ )** The equilibrium constant for the autoionization of water; equal to  $1.0 \times 10^{-14}$  at 298 K.  $K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$

**ionic atmosphere** A cluster of ions of net opposite charge surrounding a given ion in solution.

**ionic bonding** The idealized type of bonding based on the attraction of oppositely charged ions that arise through electron transfer between atoms with large differences in their tendencies to lose or gain electrons (typically metals and nonmetals).

**ionic compound** A compound that consists of oppositely charged ions.

**ionic radius** The size of an ion as measured by the distance between the nuclei of adjacent ions in a crystalline ionic compound.

**ionic solid** A solid whose unit cell contains cations and anions.

**ionization** In nuclear chemistry, the process by which an atom absorbs energy from a high-energy radioactive particle and loses an electron to become ionized.

**ionization energy (IE)** The energy (in kJ) required for complete removal of 1 mol of electrons from 1 mol of gaseous atoms or ions.

**ionizing radiation** The high-energy radiation from natural and artificial sources that forms ions in a substance by causing electron loss.

**ion-induced dipole force** The attractive force between an ion and the dipole it induces in the electron cloud of a nearby nonpolar molecule.

**isoelectronic** Having the same number and configuration of electrons as another species.

**isomer** One of two or more compounds with the same molecular formula but different properties, often as a result of different arrangements of atoms.

**isothermal process** A process that takes place at constant temperature.

**isotopes** Atoms of a given atomic number (that is, of a specific element) that have different numbers of neutrons and therefore different mass numbers.

**isotopic mass** The mass (in amu) of an isotope relative to the mass of carbon-12.

## J

**joule (J)** The SI unit of energy;  $1 \text{ J} = 1 \text{ kg}\cdot\text{m}^2/\text{s}^2$ .

## K

**kelvin (K)** The SI base unit of temperature. The kelvin is the same size as the Celsius degree.

**Kelvin scale** (also *absolute scale*) The preferred temperature scale in scientific work, which has absolute zero (0 K, or  $-273.15^\circ\text{C}$ ) as the lowest temperature.

**ketone** An organic compound (ending, *-one*) that contains a car-

**kilogram (kg)** The SI base unit of mass.

**kinetic energy ( $E_k$ )** The energy an object has because of its motion.

**kinetic-molecular theory** The model that explains macroscopic gas behavior in terms of particles in random motion whose volumes and interactions are negligible.

## L

**lanthanide contraction** The additional decrease in atomic and ionic size, beyond the expected trend, caused by the poor shielding of the increasing nuclear charge by  $f$  electrons in the elements following the lanthanides.

**lanthanides** (also *rare earth elements*) The Period 6 ( $4f$ ) series of inner transition elements, which includes cerium (Ce;  $Z = 58$ ) through lutetium (Lu;  $Z = 71$ ).

**lattice** The three-dimensional arrangement of points created by choosing each point to be at the same location within each particle of a crystal; thus, the lattice consists of all points with identical surroundings.

**lattice energy ( $\Delta H_{\text{lattice}}^\circ$ )** The enthalpy change (always positive) that accompanies the separation of 1 mol of a solid ionic compound into gaseous ions.

**law** (See *natural law*.)

**law of chemical equilibrium** (also *law of mass action*) The law stating that when a system reaches equilibrium at a given temperature, the ratio of quantities that make up the reaction quotient has a constant numerical value.

**law of conservation of energy** (also *first law of thermodynamics*) A basic observation that the total energy of the universe is constant; thus,  $\Delta E_{\text{universe}} = \Delta E_{\text{system}} + \Delta E_{\text{surroundings}} = 0$ .

**law of definite (or constant) composition** A mass law stating that, no matter what its source, a particular compound is composed of the same elements in the same parts (fractions) by mass.

**law of mass action** (See *law of chemical equilibrium*.)

**law of mass conservation** A mass law stating that the total mass of substances does not change during a chemical reaction.

**law of multiple proportions** A mass law stating that if elements A and B react to form two or more compounds, the different masses of B that combine with a fixed mass of A can be expressed as a ratio of small whole numbers.

**Le Châtelier's principle** A principle stating that if a system in a state of equilibrium is disturbed, it will undergo a change that shifts its equilibrium position in a direction that reduces the effect of the disturbance.

**leaching** A hydrometallurgical process that extracts a metal selectively, usually through formation of a complex ion.

**level** (also *shell*) A specific energy state of an atom given by the principal quantum number  $n$ .

**leveling effect** The inability of a solvent to distinguish the strength of an acid (or base) that is stronger than the conjugate acid (or conjugate base) of the solvent.

**Lewis acid-base definition** A model of acid-base behavior in which acids and bases are defined, respectively, as species that accept and donate an electron pair.

**Lewis electron-dot symbol** A notation in which the element symbol represents the nucleus and inner electrons and surrounding dots represent the valence electrons.

**Lewis structure** (also *Lewis formula*) A structural formula consisting of electron-dot symbols, with lines as bonding pairs and dots as lone pairs.

**ligand** A molecule or anion bonded to a central metal ion in a complex ion.

**like-dissolves-like rule** An empirical observation stating that substances having similar kinds of intermolecular forces dissolve in each other.

**like-dissolves-like rule** An empirical observation stating that substances having similar kinds of intermolecular forces dissolve in each other.

**limiting reactant** (also *limiting reagent*) The reactant that is consumed when a reaction occurs and, therefore, the one that determines the maximum amount of product that can form.

**line spectrum** A series of separated lines of different colors representing photons whose wavelengths are characteristic of an element. (See also *emission spectrum*.)

**linear arrangement** The geometric arrangement obtained when two electron groups maximize their separation around a central atom.

**linear shape** A molecular shape formed by three atoms lying in a straight line, with a bond angle of  $180^\circ$  (shape class  $AX_2$  or  $AX_2E_3$ ).

**linkage isomers** Coordination compounds in which the complex ions have the same composition but with different ligand donor atoms linked to the central metal ion.

**lipid** Any of a class of biomolecules, including fats, that are soluble in nonpolar solvents and not soluble in water.

**lipid bilayer** An extended sheetlike double layer of phospholipid molecules that forms in water and has the charged heads of the molecules on the surfaces of the bilayer and the nonpolar tails within the interior.

**liquid** One of the three states of matter. A liquid fills a container to the extent of its own volume and thus forms a surface.

**liquid crystal** A substance that flows like a liquid but packs like a crystalline solid at the molecular level.

**liter (L)** A non-SI unit of volume equivalent to 1 cubic decimeter ( $0.001 \text{ m}^3$ ).

**lithosphere** The solid region of Earth's crust.

**lock-and-key model** A model of enzyme function that pictures the enzyme active site and the substrate as rigid shapes that fit together as a lock and key, respectively.

**London force** (See *dispersion force*.)

**lone pair** (also *unshared pair*) An electron pair that is part of an atom's valence level but not involved in covalent bonding.

**low-spin complex** Complex ion that has fewer unpaired electrons than in the free metal ion because of the presence of strong-field ligands.

## M

**macromolecule** (See *polymer*.)

**magnetic quantum number ( $m_l$ )** An integer from  $-l$  through 0 to  $+l$  that specifies the orientation of an atomic orbital in the three-dimensional space about the nucleus.

**manometer** A device used to measure the pressure of a gas in a laboratory experiment.

**mantle** A thick homogeneous layer of Earth's internal structure that lies between the core and the crust.

**mass** The quantity of matter an object contains. Balances are designed to measure mass.

**mass-action expression** (See *reaction quotient*.)

**mass fraction** (See *fraction by mass*.)

**mass number ( $A$ )** The total number of protons and neutrons in the nucleus of an atom.

**mass percent** (also *mass %* or *percent by mass*) The fraction by mass expressed as a percentage. (45) A concentration term [% (w/w)]

expressed as the mass of solute dissolved in 100. parts by mass of solution.

**mass spectrometry** An instrumental method for measuring the relative masses of particles in a sample by creating charged particles and separating them according to their mass/charge ratios.

**matter** Anything that possesses mass and occupies volume.

**mean free path** The average distance a particle travels between collisions at a given temperature and pressure.

**melting** (also *fusion*) The change of a substance from a solid to a liquid.

**melting point (mp or  $T_f$ )** The temperature at which the solid and liquid forms of a substance are at equilibrium.

**metabolic pathway** A biochemical reaction sequence that flows in one direction, with each reaction catalyzed by an enzyme.

**metal** A substance or mixture that is relatively shiny and malleable and is a good conductor of heat and electricity. In reactions, metals tend to transfer electrons to nonmetals and form ionic compounds.

**metallic bonding** An idealized type of bonding based on the attraction between metal ions and their delocalized valence electrons. (See also *electron-sea model*.)

**metallic radius** One-half the shortest distance between the nuclei of adjacent individual atoms in a crystal of an element.

**metallic solid** A solid whose individual atoms are held together by metallic bonding.

**metalloid** (also *semimetal*) An element with properties between those of metals and nonmetals.

**metallurgy** The branch of materials science concerned with the extraction and utilization of metals.

**metathesis reaction** (also *double-displacement reaction*) A reaction in which atoms or ions of two compounds exchange bonding partners. Precipitation and acid-base reactions are examples.

**meter (m)** The SI base unit of length. The distance light travels in a vacuum in  $1/299,792,458$  second.

**methanogenesis** The process of producing methane by anaerobic biodegradation of plant and animal waste.

**Michaelis constant ( $K_M$ )** A combination of rate constants in enzyme kinetics.

**Michaelis-Menten equation** An equation that describes the kinetics of an enzyme-catalyzed reaction in terms of the initial concentrations of enzyme and substrate.

$$\text{Rate} = \frac{k_2[E]_0[S]}{K_M + [S]}$$

**microstate** An instantaneous, quantized state of a system of particles throughout which the total energy of the system is dispersed.

**milliliter (mL)** A volume (0.001 L) equivalent to  $1 \text{ cm}^3$ .

**millimeter of mercury (mmHg)** A unit of pressure based on the difference in the heights of mercury in a barometer or manometer. Renamed the *torr* in honor of Torricelli.

**mineral** The portion of an ore that contains the element of interest; a naturally occurring, homogeneous, crystalline inorganic solid, with a well-defined composition.

**miscible** Soluble in any proportion.

**mixture** Two or more elements and/or compounds that are physically intermingled but not chemically combined.

**MO bond order** One-half the difference between the number of electrons in bonding MOs and the number in antibonding MOs.

**model** (also *theory*) A simplified conceptual picture based on experiment that explains how a natural phenomenon occurs.

**molality ( $m$ )** A concentration term expressed as number of moles of solute dissolved in 1000 g (1 kg) of solvent.

**molar heat capacity ( $C_m$ )** The quantity of heat required to change the temperature of 1 mol of a substance by 1 K.

**molar mass ( $\mathcal{M}$ )** The mass of 1 mol of entities (atoms, molecules, or formula units) of a substance, in units of g/mol.

**molarity ( $M$ )** A unit of concentration expressed as the moles of solute dissolved in 1 L of solution.

**mole (mol)** The SI base unit for amount of a substance. The amount that contains a number of entities equal to the number of atoms in exactly 12 g of carbon-12 (which is  $6.022 \times 10^{23}$ ).

**mole fraction ( $X$ )** A concentration term expressed as the ratio of number of moles of solute to the total number of moles (solute plus solvent).

**molecular equation** A chemical equation showing a reaction in solution in which reactants and products appear as intact, undissociated compounds.

**molecular formula** A formula that shows the actual number of atoms of each element in a molecule of a compound.

**molecular mass** (also *molecular weight*) The sum (in amu) of the atomic masses of the elements in a molecule (or formula unit) of a compound.

**molecular orbital (MO)** An orbital of given energy and shape that extends over a molecule and can be occupied by no more than two paired electrons.

**molecular orbital (MO) diagram** A depiction of the relative energy and number of electrons in each MO, as well as the atomic orbitals from which the MOs form.

**molecular orbital (MO) theory** A model that describes a molecule as a collection of nuclei and electrons in which the electrons occupy orbitals that extend over the entire molecule.

**molecular polarity** The overall distribution of electronic charge in a molecule, determined by its shape and bond polarities.

**molecular shape** The three-dimensional arrangement of the atomic nuclei in a molecule.

**molecular solid** A solid held together by intermolecular forces between individual molecules.

**molecular weight** (See *molecular mass*.)

**molecularity** The number of reactant particles involved in an elementary step.

**molecule** A structure consisting of two or more atoms that are bound chemically and behave as an independent unit.

**monatomic ion** An ion derived from a single atom.

**monomer** A small molecule, linked covalently to others of the same or similar type to form a polymer; the repeat unit of the polymer.

**mononucleotide** A monomer unit of a nucleic acid, consisting of an N-containing base, a sugar, and a phosphate group.

**monosaccharide** A simple sugar; a polyhydroxy ketone or aldehyde with three to nine C atoms.

## N

**nanotechnology** The science and engineering of nanoscale systems (size range of 1–100 nm).

**natural law** (also *law*) A summary, often in mathematical form, of a universal observation.

**Nernst equation** An equation stating that the voltage of an electrochemical cell under any conditions depends on the standard cell voltage and the concentrations of the cell components:

$$E_{\text{cell}} = E_{\text{cell}}^{\circ} - \frac{RT}{nF} \ln Q$$

**net ionic equation** A chemical equation of a reaction in solution in which spectator ions have been eliminated to show the actual chemical change.

**network covalent solid** A solid in which all the atoms are bonded covalently so that individual molecules are not present.

**neutralization** Process that occurs when an  $\text{H}^+$  ion from an acid combines with an  $\text{OH}^-$  ion from a base to form  $\text{H}_2\text{O}$ .

**neutralization reaction** An acid-base reaction that yields water and a solution of a salt; when the  $\text{H}^+$  ions of a strong acid react with an equivalent amount of the  $\text{OH}^-$  ions of a strong base, the solution is neutral.

**neutron ( $n^0$ )** An uncharged subatomic particle found in the nucleus, with a mass slightly greater than that of a proton.

**nitride** An organic compound containing the  $-\text{C}\equiv\text{N}:$  group.

**node** A point at which a wave function passes through zero (has zero amplitude). The probability of finding the electron at a node is zero.

**nonbonding MO** A molecular orbital that is not involved in bonding.

**nonelectrolyte** A substance whose aqueous solution does not conduct an electric current.

**nonmetal** An element that lacks metallic properties. In reactions, nonmetals tend to share electrons with each other to form covalent compounds or accept electrons from metals to form ionic compounds.

**nonpolar covalent bond** A covalent bond between identical atoms in which the bonding pair is shared equally.

**nuclear binding energy** The energy required to break 1 mol of nuclei of an element into individual nucleons.

**nuclear magnetic resonance (NMR) spectroscopy** An instrumental technique used to determine the molecular environment of a given type of nucleus, most often  $^1\text{H}$ , from its absorption of radio waves in a magnetic field.

**nuclear transmutation** The induced conversion of one nucleus into another by bombardment with a particle.

**nucleic acid** An unbranched polymer of mononucleotides that occurs as two types, DNA and RNA (deoxyribonucleic and ribonucleic acids), which differ chemically in the nature of the sugar portion of their mononucleotides.

**nucleon** An elementary particle found in the nucleus of an atom; a proton or neutron.

**nucleus** The tiny central region of the atom that contains all the positive charge and essentially all the mass.

**nuclide** A nuclear species with specific numbers of protons and neutrons.

## O

**observation** A fact obtained with the senses, often with the aid of instruments. Quantitative observations provide data that can be compared.

**occurrence** (also *source*) The form(s) in which an element exists in nature.

**octahedral arrangement** The geometric arrangement obtained when six electron groups maximize their space around a central atom; when all six groups are bonding groups, the molecular shape is octahedral ( $\text{AX}_6$ ; ideal bond angle =  $90^\circ$ ).

**octet rule** The observation that when atoms bond, they often lose, gain, or share electrons to attain a filled outer level of eight electrons (or two for H and Li).

**optical isomers** (also *enantiomers*) A pair of stereoisomers consisting of a molecule and its mirror image that cannot be superimposed on each other.

**optically active** Able to rotate the plane of polarized light.

**orbital diagram** A depiction of orbital occupancy in terms of electron number and spin shown by means of arrows in a series of small boxes or on a series of short lines.

**ore** A naturally occurring compound or mixture of compounds from which an element can be profitably extracted.

**organic compound** A compound in which carbon is nearly always bonded to one or more other carbons and to hydrogen, and often to other elements.

**organometallic compound** An organic compound in which a carbon (in an R group) has a polar covalent bond to a metal atom.

**osmosis** The process by which solvent flows through a semipermeable membrane from a dilute to a concentrated solution.

**osmotic pressure (II)** The pressure that results from the ability of solvent, but not solute, particles to cross a semipermeable membrane. The pressure required to prevent the net movement of solvent across the membrane.

**outer electrons** Electrons that occupy the highest energy level (highest  $n$  value) and are, on average, farthest from the nucleus.

**overall (net) equation** A chemical equation that is the sum of two or more balanced sequential equations in which a product of one becomes a reactant for the next.

**overvoltage** The additional voltage, usually associated with gaseous products forming at an electrode, that is required above the standard cell voltage to accomplish electrolysis.

**oxidation** The loss of electrons by a species, accompanied by an increase in oxidation number.

**oxidation number (O.N.)** (also *oxidation state*) A number equal to the magnitude of the charge an atom would have if its shared electrons were transferred to the atom that attracts them more strongly.

**oxidation-reduction reaction** (also *redox reaction*) A process in which there is a net movement of electrons from one reactant (reducing agent) to another (oxidizing agent).

**oxidation state** (See *oxidation number*.)

**oxidizing agent** The substance that accepts electrons in a reaction and undergoes a decrease in oxidation number.

**oxoanion** An anion in which an element, usually a nonmetal, is bonded to one or more oxygen atoms.

## P

**$p$  orbital** An atomic orbital with  $l = 1$ .

**packing efficiency** The percentage of the total volume occupied by atoms, ions, or molecules in a unit cell.

**paramagnetism** The tendency of a species with unpaired electrons to be attracted by an external magnetic field.

**partial ionic character** An estimate of the actual charge separation in a bond (caused by the electronegativity difference of the bonded atoms) relative to complete separation.

**partial pressure** The portion of the total pressure contributed by a gas in a mixture of gases.

**particle accelerator** A device used to impart high kinetic energies to nuclear particles.

**pascal (Pa)** The SI unit of pressure;  $1 \text{ Pa} = 1 \text{ N/m}^2$ .

**penetration** The phenomenon in which an outer electron moves through the region occupied by the core electrons to spend part of its time closer to the nucleus; penetration increases the average effective nuclear charge for that electron.

**percent by mass (mass %)** (also *mass percent*) The fraction by mass expressed as a percentage.

**percent yield (% yield)** The actual yield of a reaction expressed as a percentage of the theoretical yield.

**period** A horizontal row of the periodic table.

**periodic law** A law stating that when the elements are arranged by atomic mass, they exhibit a periodic recurrence of properties.

**periodic table of the elements** A table in which the elements are arranged by atomic number into columns (groups) and rows (periods).

**pH** The negative of the common logarithm of  $[\text{H}_3\text{O}^+]$ .

**phase** A physically distinct and homogeneous part of a system.

**phase change** A physical change from one phase to another, usually referring to a change in physical state.

**phase diagram** A diagram used to describe the stable phases and phase changes of a substance as a function of temperature and pressure.

**photoelectric effect** The observation that when monochromatic light of sufficient frequency shines on a metal, an electric current is produced.

**photon** A quantum of electromagnetic radiation.

**photovoltaic cell** A device capable of converting light directly into electricity.

**physical change** A change in which the physical form (or state) of a substance, but not its composition, is altered.

**physical property** A characteristic shown by a substance itself, without interacting with or changing into other substances.

**pi ( $\pi$ ) bond** A covalent bond formed by sideways overlap of two atomic orbitals that has two regions of electron density, one above and one below the internuclear axis.

**pi ( $\pi$ ) MO** A molecular orbital formed by combination of two atomic (usually  $p$ ) orbitals whose orientations are perpendicular to the internuclear axis.

**Planck's constant ( $h$ )** A proportionality constant relating the energy and frequency of a photon, equal to  $6.626 \times 10^{-34} \text{ J}\cdot\text{s}$ .

**plastic** A material that, when deformed, retains its new shape.

**polar covalent bond** A covalent bond in which the electron pair is shared unequally, so the bond has partially negative and partially positive poles.

**polar molecule** A molecule with an unequal distribution of charge as a result of its polar bonds and shape.

**polarimeter** A device used to measure the rotation of plane-polarized light by an optically active compound.

**polarizability** The ease with which a particle's electron cloud can be distorted.

**polyatomic ion** An ion in which two or more atoms are bonded covalently.

**polymer** (also *macromolecule*) An extremely large molecule that results from the covalent linking of many simpler molecular units (monomers).

**polyprotic acid** An acid with more than one ionizable proton.

**polysaccharide** A macromolecule composed of many monosaccharides linked covalently.

**positron ( $\beta^+$ )** The antiparticle of an electron.

**positron emission** A type of radioactive decay in which a positron is emitted from a nucleus.

**potential energy ( $E_p$ )** The energy an object has as a result of its position relative to other objects or because of its composition.

**precipitate** The insoluble product of a precipitation reaction.

**precipitation reaction** A reaction in which two soluble ionic compounds form an insoluble product, a precipitate.

**precision** (also *reproducibility*) The closeness of a measurement to other measurements of the same phenomenon in a series of experiments.

**pressure ( $P$ )** The force exerted per unit of surface area.

**pressure-volume work ( $PV$  work)** A type of mechanical work done when a volume change occurs against an external pressure.

**principal quantum number ( $n$ )** A positive integer that specifies the energy and relative size of an atomic orbital; a number that specifies an energy level in an atom.

**probability contour** A shape that defines the volume around an atomic nucleus within which an electron spends a given percentage of its time.

**product** A substance formed in a chemical reaction.

**property** A characteristic that gives a substance its unique identity.

**protein** A natural, unbranched polymer composed of any of about 20 types of amino acid monomers linked together by peptide bonds.

**proton ( $p^+$ )** A subatomic particle found in the nucleus that has a unit positive charge ( $1.60218 \times 10^{-19}$  C).

**proton acceptor** A species that accepts an  $H^+$  ion; a Brønsted-Lowry base.

**proton donor** A species that donates an  $H^+$  ion; a Brønsted-Lowry acid.

**pseudo-first-order** A reaction with a rate law that appears to be first-order because all reactants except one are present in such large concentrations.

**pseudo-noble gas configuration** The  $(n-1)d^{10}$  configuration of a  $p$ -block metal ion that has an empty outer energy level.

## Q

**quantum** A packet of energy equal to  $h\nu$ . The smallest quantity of energy that can be emitted or absorbed.

**quantum mechanics** The branch of physics that examines the wave nature of objects on the atomic scale.

**quantum number** A number that specifies a property of an orbital or an electron.

## R

**rad (radiation-absorbed dose)** The quantity of radiation that results in 0.01 J of energy being absorbed per kilogram of tissue;  $1 \text{ rad} = 0.01 \text{ J/kg tissue} = 10^{-2} \text{ Gy}$ .

**radial probability distribution plot** The graphic depiction of the total probability distribution (sum of  $\psi^2$ ) of an electron in the region near the nucleus.

**radioactivity** The emissions resulting from the spontaneous disintegration of an unstable nucleus.

**radioisotope** An isotope with an unstable nucleus that decays through radioactive emissions.

**radioisotopic dating** A method for determining the age of an object based on the rate of decay of a particular radioactive nuclide relative to a stable nuclide.

**radius of gyration ( $R_g$ )** A measure of the size of a coiled polymer chain, expressed as the average distance from the center of mass of the chain to its outside edge.

**random coil** The shape adopted by most polymer chains and caused by random rotation about the bonds joining the repeat units.

**random error** Error that occurs in all measurements (with its size depending on the measurer's skill and the instrument's precision) and results in values *both* higher and lower than the actual value.

**Raoult's law** A law stating that the vapor pressure of solvent above a solution equals the mole fraction of solvent times the vapor pressure of pure solvent:  $P_{\text{solvent}} = X_{\text{solvent}} \times P^{\circ}_{\text{solvent}}$ .

**rare earths** (See *lanthanides*.)

**rate constant ( $k$ )** The proportionality constant that relates reaction rate to reactant (and product) concentrations.

**rate law (also rate equation)** An equation that expresses the rate of a reaction as a function of reactant (and product) concentrations and temperature.

**rate-determining step (also rate-limiting step)** The slowest step in a reaction mechanism and therefore the step that limits the overall rate.

**reactant** A starting substance in a chemical reaction.

**reaction energy diagram** A graph that shows the potential energy of a reacting system as it progresses from reactants to products.

**reaction intermediate** A substance that is formed and used up during the overall reaction and therefore does not appear in the overall equation.

**reaction mechanism** A series of elementary steps that sum to the overall reaction and is consistent with the rate law.

**reaction order** The exponent of a reactant concentration in a rate law that shows how the rate is affected by changes in that concentration.

**reaction quotient ( $Q$ ) (also mass-action expression)** A ratio of terms for a given reaction consisting of product concentrations multiplied together and divided by reactant concentrations multiplied together, with each concentration raised to the power of its balancing coefficient. The value of  $Q$  changes until the system reaches equilibrium, at which point it equals  $K$ .

**reaction rate** The change in the concentrations of reactants (or products) with time.

**reactor core** The part of a nuclear reactor that contains the fuel rods and generates heat from fission.

**redox reaction** (See *oxidation-reduction reaction*.)

**reducing agent** The substance that donates electrons in a redox reaction and undergoes an increase in oxidation number.

**reduction** The gain of electrons by a species, accompanied by a decrease in oxidation number.

**refraction** A phenomenon in which a wave changes its speed and therefore its direction as it passes through a phase boundary into a different medium.

**rem (roentgen equivalent for man)** The unit of radiation dosage for a human based on the product of the number of rads and a factor related to the biological tissue;  $1 \text{ rem} = 10^{-2} \text{ Sv}$ .

**reproducibility** (See *precision*.)

**resonance hybrid** The weighted average of the resonance structures for a species.

**resonance structure (also resonance form)** One of two or more Lewis structures for a species that cannot be adequately depicted by a single structure. Resonance structures differ only in the position of bonding and lone electron pairs.

**reverse osmosis** A process for preparing drinkable water that uses an applied pressure greater than the osmotic pressure to remove ions from an aqueous solution, typically seawater.

**reversible process** A process that occurs in such tiny increments that the system remains at equilibrium and the direction of the change can be reversed by an infinitesimal reversal of conditions.

**rms (root-mean-square) speed ( $u_{\text{rms}}$ )** The speed of a molecule having the average kinetic energy; very close to the most probable speed.

**roasting** A pyrometallurgical process in which metal sulfides are converted to oxides.

**round off** The process of removing digits based on a series of rules to obtain an answer with the proper number of significant figures (or decimal places).

## S

**s orbital** An atomic orbital with  $l = 0$ .

**salt** An ionic compound that results from an acid-base reaction after solvent is removed.

**salt bridge** An inverted U tube containing a solution of nonreacting ions that connects the compartments of a voltaic cell and maintains neutrality by allowing ions to flow between compartments.

**saturated hydrocarbon** A hydrocarbon in which each C is bonded to four other atoms.

**saturated solution** A solution that contains the maximum amount of dissolved solute at a given temperature (prepared with undissolved solute present).

**scanning tunneling microscopy** An instrumental technique that uses electrons moving across a minute gap to observe the topography of a surface on the atomic scale.

**Schrödinger equation** An equation that describes how the electron matter-wave changes in space around the nucleus. Solutions of the equation provide energy states associated with the atomic orbitals.

**scientific method** A process of creative proposals and testing aimed at objective, verifiable discoveries of the causes of natural events.

**scintillation counter** A device used to detect radioactive emissions through their excitation of atoms, which subsequently emit light.

**screening** (See *shielding*.)

**second (s)** The SI base unit of time.

**second law of thermodynamics** A law stating that a process occurs spontaneously in the direction that increases the entropy of the universe.

**seesaw shape** A molecular shape caused by the presence of one equatorial lone pair in a trigonal bipyramidal arrangement ( $AX_4E$ ).

**selective precipitation** The process of separating ions through differences in the solubility of their compounds with a given precipitating ion.

**self-ionization** (See *autoionization*.)

**semiconductor** A substance whose electrical conductivity is poor at room temperature but increases significantly with rising temperature.

**semimetal** (See *metalloid*.)

**semipermeable membrane** A membrane that allows solvent, but not solute, to pass through.

**shared pair** (See *bonding pair*.)

**shell** (See *level*.)

**shielding** (also *screening*) The ability of other electrons, especially those occupying inner orbitals, to lessen the nuclear attraction for an outer electron.

**SI unit** A unit composed of one or more of the base units of the *Système International d'Unités*, a revised form of the metric system.

**side reaction** An undesired chemical reaction that consumes some of the reactant and reduces the overall yield of the desired product.

**sievert (Sv)** The SI unit of human radiation dosage; 1 Sv = 100 rem.

**sigma ( $\sigma$ ) bond** A type of covalent bond that arises through end-to-end orbital overlap and has most of its electron density along an imaginary line joining the nuclei.

**sigma ( $\sigma$ ) MO** A molecular orbital that is cylindrically symmetrical about an imaginary line that runs through the nuclei of the component atoms.

**significant figures** The digits obtained in a measurement. The greater the number of significant figures, the greater the certainty of the measurement.

**silicate** A type of compound found throughout rocks and soil and consisting of repeating  $—Si—O—$  groupings and, in most cases, metal cations.

**silicone** A type of synthetic polymer containing  $—Si—O$  repeat units, with organic groups and crosslinks.

**simple cubic unit cell** A unit cell in which a particle occupies each corner of a cube.

**single bond** A bond that consists of one electron pair.

**slag** A molten waste product formed in a blast furnace by the reaction of acidic silica with a basic metal oxide.

**smelting** Heating an oxide form of a mineral with a reducing agent, such as coke, to obtain a metal.

**soap** The salt formed in a reaction between a fatty acid and a strong base, usually a Group 1A(1) or 2A(2) hydroxide.

**solid** One of the three states of matter. A solid has a fixed shape that does not conform to the container shape.

**solubility (S)** The maximum amount of solute that dissolves in a fixed quantity of a particular solvent at a specified temperature.

**solubility-product constant ( $K_{sp}$ )** An equilibrium constant for a slightly soluble ionic compound dissolving in water.

**solute** The substance that dissolves in the solvent.

**solution** (See *homogeneous mixture*.)

**solvated** Surrounded closely by solvent molecules.

**solvation** The process of surrounding a solute particle with solvent particles.

**solvent** The substance in which one or more solutes dissolve.

**source** (See *occurrence*.)

**sp hybrid orbital** An orbital formed by the mixing of one *s* and one *p* orbital of a central atom.

**sp<sup>2</sup> hybrid orbital** An orbital formed by the mixing of one *s* and two *p* orbitals of a central atom.

**sp<sup>3</sup> hybrid orbital** An orbital formed by the mixing of one *s* and three *p* orbitals of a central atom.

**sp<sup>3</sup>d hybrid orbital** An orbital formed by the mixing of one *s*, three *p*, and one *d* orbital of a central atom.

**sp<sup>3</sup>d<sup>2</sup> hybrid orbital** An orbital formed by the mixing of one *s*, three *p*, and two *d* orbitals of a central atom.

**specific heat capacity (c)** The quantity of heat required to change the temperature of 1 gram of a substance or material by 1 K.

**spectator ion** An ion that is present as part of a reactant but is not involved in the chemical change.

**spectrochemical series** A ranking of ligands in terms of their ability to split *d*-orbital energies.

**spectrometry** Any instrumental technique that uses a portion of the electromagnetic spectrum to measure the atomic and molecular energy levels of a substance.

**speed of light (c)** A fundamental constant giving the speed at which electromagnetic radiation travels in a vacuum:  $c = 2.99792458 \times 10^8$  m/s.

**spin quantum number ( $m_s$ )** A number, either  $+\frac{1}{2}$  or  $-\frac{1}{2}$ , that indicates the direction of electron spin.

**spontaneous change** A change that occurs under specified conditions without an ongoing input of external energy.

**square planar shape** A molecular shape ( $AX_4E_2$ ) caused by the presence of two lone pairs at opposite vertices in an octahedral electron-group arrangement.

**square pyramidal shape** A molecular shape ( $AX_5E$ ) caused by the presence of one lone pair in an octahedral electron-group arrangement.

**standard atmosphere (atm)** The average atmospheric pressure measured at sea level and 0°C, defined as  $1.01325 \times 10^5$  Pa.

**standard cell potential ( $E^\circ_{cell}$ )** The potential of a cell measured with all components in their standard states and no current flowing.

**standard electrode potential ( $E^\circ_{half-cell}$ )** (also *standard half-cell potential*) The standard potential of a half-cell, with the half-reaction written as a reduction.

**standard enthalpy of formation ( $\Delta H^\circ_f$ )** (also *standard heat of formation*) The enthalpy change occurring when 1 mol of a compound forms from its elements with all components in their standard states.

**standard enthalpy of reaction ( $\Delta H^\circ_{rxn}$ )** (also *standard heat of reaction*) The enthalpy change that occurs during a reaction when all components are in their standard states.

**standard entropy of reaction ( $\Delta S^\circ_{rxn}$ )** The entropy change that occurs when all components are in their standard states.

**standard free energy change ( $\Delta G^\circ$ )** The free energy change that occurs when all components of a system are in their standard states.

**standard free energy of formation ( $\Delta G_f^\circ$ )** The standard free energy change that occurs when 1 mol of a compound is made from its elements with all components in their standard states.

**standard half-cell potential** (See *standard electrode potential*.)

**standard heat of formation** (See *standard enthalpy of formation*.)

**standard heat of reaction** (See *standard enthalpy of reaction*.)

**standard hydrogen electrode** (See *standard reference half-cell*.)

**standard molar entropy ( $S^\circ$ )** The entropy of 1 mol of a substance in its standard state.

**standard molar volume** The volume of 1 mol of an ideal gas at standard temperature and pressure: 22.4141 L.

**standard reference half-cell** (also *standard hydrogen electrode*) A specially prepared platinum electrode immersed in 1 M  $H^+(aq)$  through which  $H_2$  gas at 1 atm is bubbled.  $E^\circ_{\text{half-cell}}$  is defined as 0 V.

**standard state** A set of specific conditions used to compare thermodynamic data: 1 atm for gases behaving ideally, 1 M for dissolved species, or the pure substance for liquids and solids.

**standard temperature and pressure (STP)** The reference conditions for a gas: 0°C (273.15 K) and 1 atm (760 torr)

**state function** A property of a system determined only by the system's current state, regardless of how it arrived at that state.

**state of matter** One of the three physical forms of matter: solid, liquid, or gas.

**stationary state** In the Bohr model, one of the allowable energy levels of the atom in which it does not release or absorb energy.

**steady-state approximation** The approximation that the concentrations of reaction intermediates remain constant during reaction because the net rate of formation = 0.

**steel** An alloy of iron with small amounts of carbon and usually other metals.

**stellar nucleosynthesis** The process by which elements are formed in the stars through nuclear fusion.

**stereoisomers** Molecules with the same arrangement of atoms but different orientations of groups in space. (See also *geometric isomers* and *optical isomers*.)

**stoichiometric coefficient** (See *balancing coefficient*.)

**stoichiometry** The study of the mass-mole-number relationships of chemical formulas and reactions.

**strong force** An attractive force that exists between all nucleons and is many times stronger than the electrostatic repulsive force.

**strong-field ligand** A ligand that causes larger crystal field splitting energy and therefore is part of a low-spin complex.

**structural formula** A formula that shows the actual number of atoms, their relative placement, and the bonds between them.

**structural isomers** (See *constitutional isomers*.)

**sublevel** (also *subshell*) An energy substate of an atom within a level. Given by the  $n$  and  $l$  values, the sublevel designates the size and shape of the atomic orbitals.

**sublimation** The process by which a solid changes directly into a gas.

**substance** A type of matter, either an element or a compound, that has a fixed composition.

**substitution reaction** An organic reaction that occurs when an atom (or group) from one reactant substitutes for one attached to a carbon in another reactant.

**substrate** A reactant that binds to the active site in an enzyme-catalyzed reaction.

**superconductivity** The ability to conduct a current with no loss of energy to resistive heating.

**supersaturated solution** An unstable solution in which more solute is dissolved than in a saturated solution.

**surface tension** The energy required to increase the surface area of a liquid by a given amount.

**surroundings** All parts of the universe other than the system being considered.

**suspension** A heterogeneous mixture containing particles that are visibly distinct from the surrounding fluid.

**synthetic natural gas (SNG)** A gaseous fuel mixture, mostly methane, formed from coal.

**system** The defined part of the universe under study.

**systematic error** A type of error producing values that are all either higher or lower than the actual value, often caused by faulty equipment or a consistent flaw in technique.

## T

**T shape** A molecular shape caused by the presence of two equatorial lone pairs in a trigonal bipyramidal arrangement ( $AX_3E_2$ ).

**$t_{2g}$  orbitals** The set of orbitals (composed of  $d_{xy}$ ,  $d_{yz}$ , and  $d_{xz}$ ) that results when the energies of the metal-ion  $d$  orbitals are split by a ligand field. This set is lower in energy than the other ( $e_g$ ) set in an octahedral field and higher in energy in a tetrahedral field.

**temperature ( $T$ )** A measure of how hot or cold a substance is relative to another substance. A measure of the average kinetic energy of the particles in a sample.

**tetrahedral arrangement** The geometric arrangement formed when four electron groups maximize their separation around a central atom; when all four groups are bonding groups, the molecular shape is tetrahedral ( $AX_4$ ; ideal bond angle 109.5°).

**theoretical yield** The amount of product predicted by the stoichiometrically equivalent molar ratio in the balanced equation.

**theory** (See *model*.)

**thermochemical equation** A balanced chemical equation that includes the enthalpy change for the reaction.

**thermochemistry** The branch of thermodynamics that focuses on the heat involved in chemical and physical change.

**thermodynamics** The study of energy and its transformations.

**thermometer** A device for measuring temperature that contains a fluid that expands or contracts within a graduated tube.

**third law of thermodynamics** A law stating that the entropy of a perfect crystal is zero at 0 K.

**titration** A method of determining the concentration of a solution by monitoring the amount of a solution of known concentration needed to react with it.

**torr** A unit of pressure identical to 1 mmHg.

**total ionic equation** An equation for an aqueous reaction that shows all the soluble ionic substances dissociated into ions.

**tracer** A radioisotope that signals the presence of the species of interest via radioactive emissions.

**transcription** The process of producing messenger RNA from DNA.

**transition element** An element that occupies the  $d$  block or the  $f$  block (inner transition element) of the periodic table.

**transition state** (also *activated complex*) An unstable species formed in an effective collision of reactants that exists momentarily when the system is highest in energy and that can either form products or re-form reactants.

**transition state theory** A model that explains how the energy of reactant collisions is used to form a high-energy transitional species that can change to reactant or product.

**translation** The process by which messenger RNA specifies the sequence of amino acids to synthesize a protein.

**transuranium element** An element with atomic number higher than that of uranium ( $Z = 92$ ).

**trigonal bipyramidal arrangement** The geometric arrangement formed when five electron groups maximize their separation around a central atom. When all five groups are bonding groups, the molecular shape is trigonal bipyramidal ( $AX_5$ ; ideal bond angles, axial-center-equatorial  $90^\circ$  and equatorial-center-equatorial  $120^\circ$ ).

**trigonal planar arrangement** The geometric arrangement formed when three electron groups maximize their separation around a central atom. When all three groups are bonding groups, the molecular shape is trigonal planar ( $AX_3$ ; ideal bond angle  $120^\circ$ ).

**trigonal pyramidal shape** A molecular shape ( $AX_3E$ ) caused by the presence of one lone pair in a tetrahedral arrangement.

**triple bond** A covalent bond that consists of three bonding pairs, two atoms sharing six electrons; one  $\pi$  and two  $\sigma$  bonds.

**triple point** The pressure and temperature at which three phases of a substance are in equilibrium. In a phase diagram, the point at which three phase-transition curves meet.

**Trouton's Rule** The observation that most liquids have an entropy of vaporization value near  $88 \text{ J/mol}\cdot\text{K}$ .

**Tyndall effect** The scattering of light by a colloid.

## U

**ultraviolet (UV)** Radiation in the region of the electromagnetic spectrum between the visible and the x-ray regions.

**uncertainty** A characteristic of every measurement that results from the inexactness of the measuring device and the need to estimate when taking a reading.

**uncertainty principle** The principle stated by Heisenberg that it is impossible to know simultaneously the exact position and velocity of a particle; the principle becomes important only for particles of very small mass.

**unimolecular reaction** An elementary reaction that involves the decomposition or rearrangement of a single particle.

**unit cell** The smallest portion of a crystal that, if repeated in all three directions, yields the crystal.

**universal gas constant (R)** A proportionality constant that relates the energy, amount of substance, and temperature of a system;  $R = 0.0820578 \text{ atm}\cdot\text{L/mol}\cdot\text{K} = 8.31447 \text{ J/mol}\cdot\text{K}$ .

**unsaturated hydrocarbon** A hydrocarbon with at least one carbon-carbon multiple bond; one in which at least two C atoms are bonded to fewer than four atoms.

**unsaturated solution** A solution in which more solute can be dissolved at a given temperature.

**unshared pair** (See *lone pair*.)

## V

**V shape** (See *bent shape*.)

**valence band** In band theory, the lower energy portion of the band of molecular orbitals, which is filled with valence electrons.

**valence bond (VB) theory** A model that attempts to reconcile the shapes of molecules with those of atomic orbitals through the concepts of orbital overlap and hybridization.

**valence electrons** The electrons involved in compound formation; in main-group elements, the electrons in the valence (outer) level.

**valence-shell electron-pair repulsion (VSEPR) theory** A model explaining that the shapes of molecules and ions result from minimizing electron-pair repulsions around a central atom.

**van der Waals constants** Experimentally determined positive numbers used in the van der Waals equation to account for the interparticle attractions and particle volume of real gases.

**van der Waals equation** An equation that accounts for the behavior of real gases.

**van der Waals radius** One-half of the closest distance between the nuclei of identical nonbonded atoms.

**vapor pressure** (also *equilibrium vapor pressure*) The pressure exerted by a vapor at equilibrium with its liquid in a closed system.

**vapor pressure lowering ( $\Delta P$ )** The lowering of the vapor pressure of a solvent caused by the presence of dissolved solute particles.

**vaporization** The process of changing from a liquid to a gas.

**variable** A quantity that can have more than a single value. (See also *controlled experiment*.)

**viscosity** A measure of the resistance of a fluid to flow.

**volatility** The tendency of a substance to become a gas.

**volt (V)** The SI unit of electric potential:  $1 \text{ V} = 1 \text{ J/C}$ .

**voltage** (See *cell potential*.)

**voltaic cell** (also *galvanic cell*) An electrochemical cell that uses a spontaneous redox reaction to generate electric energy.

**volume (V)** The amount of space occupied by a sample of matter.

**volume percent [% (v/v)]** A concentration term defined as the volume of solute in 100 volumes of solution.

## W

**wastewater** Used water, usually containing industrial and/or residential waste, that is treated before being returned to the environment.

**water softening** The process of replacing the hard-water ions  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  with  $\text{Na}^+$  ions.

**wave function** A mathematical expression that describes the motion of the electron's matter-wave in terms of time and position in the region of the nucleus. The term is used qualitatively to mean the region of space in which there is a high probability of finding the electron.

**wave function** A mathematical description of the electron's matter-wave in three dimensions.

**wave-particle duality** The principle stating that both matter and energy have wavelike and particle-like properties.

**wavelength ( $\lambda$ )** The distance between any point on a wave and the corresponding point on the next wave, that is, the distance a wave travels during one cycle.

**weak-field ligand** A ligand that causes smaller crystal field splitting energy and therefore is part of a high-spin complex.

**weight** The force that is exerted by a gravitational field on an object and is directly proportional to the object's mass.

**work (w)** The energy transferred when an object is moved by a force.

## X

**x-ray diffraction analysis** An instrumental technique used to determine dimensions of a crystal structure by measuring the diffraction patterns caused by x-rays impinging on the crystal.

## Z

**zone refining** A process used to purify metals and metalloids in which impurities are removed from a bar of the element by concentrating them in a thin molten zone.

**$\beta^-$  decay** (also *negatron emission*) A radioactive process in which a high-speed electron is emitted from a nucleus.

Page numbers followed by *f* indicate figures; *mn*, marginal notes; *n*, footnotes; and *t*, tables. Page numbers preceded by "A-" indicate pages in the *Appendix*. Page numbers preceded by "G-" indicate pages in the *Glossary*.

 Actinium, 342  
 Activated complex, 719  
 Activated state, 717, 717*f*  
 Activation energy  
   calculating, 718, 718*f*, 718*t*  
   catalysis and, 730, 730*f*, 731, 735  
   defined, 716, G-1  
   importance of, 716–717  
   transition state theory and, 719–722  
 Active metals  
   activity series of metals, 184–186, 958–959, G-1  
   displacing hydrogen from water, 184, 185*f*  
   reactivity of, 958  
   reduction with, 1011, 1011*f*  
 Active site, 732–733, 733*f*; 781, 781*f*; G-1  
 Activity in radioactive decay, 1084, G-1  
 Activity series of halogens, 186, 186*f*  
 Activity series of metals, 184–186, 958–959, G-1  
 Actual yield, 128, G-1  
 Addition, significant figures and, 30–31  
 Addition polymers, 668, 668*f*, 669*t*, G-1  
 Addition reactions  
   with benzene, 660  
   defined, 651, G-1  
   organic, 651, 660, 668  
   polymers in, 668  
 Adduct, 828–829, G-1  
 Adenine, 657*f*, 675  
 Adenosine triphosphate (ATP)  
   defined, G-1  
   production of, 611, 982–983  
   universal role of, 925–926  
 Adhesive forces, 489–490, 490*f*  
 Adhesives, 518  
 Adipic acid, A-8  
 Advanced materials, 507–520  
   ceramic materials, 512–513, 512*t*, 513*f*  
   electronic materials, 507–509, 508*f*  
   liquid crystals, 509–511  
   nanotechnology and, 519–520  
   polymeric materials, 514–518, 514*t*, 515–517*f*, 518*t*  
 Aerosol, 568*t*  
 Air bags, 205  
 Air composition, 205, 207, 239, 239*t*  
 Airplane de-icers, 566  
 Air pollution  
   acid rain (*See* Acid rain)  
   automobile exhaust and, 276–277  
   chlorofluorocarbons and, 602, 602*f*, 735  
   smog and, 224, 414, 609, 609*mn*  
   thermal pollution, 550, 551*f*, 1108–1109  
 Alanine, 643, 643*f*, 644, 672*f*  
 Alchemy, 10, 10*f*, 50  
 Alcohols  
   defined, 654, G-1  
   as functional group, 654, 654*f*, 655*t*, 656  
   grain alcohol density, 24*t*  
   solubility of, 535–536, 536*f*, 536*t*

- Aldehydes, 655*t*, 660–661, 660*f*, G-1  
 Alizarin, 861*f*  
 Alizarin yellow R, 861*f*  
 Alkali metals. *See also* Halides

 types of, 568, 568*t*  
 in water purification, 570–571
- Color, 1056–1057, 1056*f*, 1057*t*, 1058–1059
- Column chromatography, 83, 83*f*
- Combination reactions, 181–182, 182*f*
- Combined gas law, 214
- Combustion. *See also* Fuels  
 biodiesel from, 281–282  
 calculating heat of reaction, 272–273  
 of coal, 281  
 defined, 11, 186, G-4  
 of gasoline, 114–115, 262, 919–920  
 of hydrogen, 281–282, 697–698  
 Lavoisier's theory of, 11, 13  
 mass conservation and, 46  
 of methane, 387–388, 388*f*  
 of octane, 114–115, 263, 263*f*; 919–920  
 phlogiston theory and, 11  
 of propane, 117, 117*t*, 911–912  
 respiration and, 187, 914  
 spontaneous change and, 897
- Combustion analysis, 108–109, 108*f*, G-4
- Combustion reactions, 186–187
- Common-ion effect, 844, 868–869, 868*f*, G-4
- Compact fluorescent lamps (CFLs), 285
- Complementary color, 1056
- Complex ions  
 amphoteric hydroxides, 881–882, 882*f*  
 calculating concentration of, 878–879  
 in coordination compounds, 1046–1054, 1046*f*, 1047*t*  
 defined, 877, 1046, G-4  
 formation of, 877–878, 878*f*; 878*t*  
 geometry of, 1047, 1047*t*  
 isomerism and, 1051–1054  
 names and formulas for, 1048–1051, 1050*t*  
 octahedral complexes and, 1055, 1055*f*  
 solubility of precipitates and, 879–881  
 square planar complexes and, 1055, 1056*f*  
 structure of, 877, 877*f*  
 table of formation constants, A-12  
 tetrahedral complexes and, 1056, 1056*f*  
 valence bond theory for, 1055–1056
- Composition of matter, 4, G-4
- Compounds  
 amount-mass-number conversions of, 100–102, 100*f*  
 atomic-scale view of, 44, 44*f*  
 bonding, 64–67  
 calculating molecular mass of, 76–78  
 comparison with mixtures, 45, 81, 81*f*  
 covalent (*See* Covalent compounds)  
 defined, 44, G-4  
 determining formula of unknown compounds, 104–111  
 elemental mass in, 48–49  
 fixed ratio, 44  
 formulas, names, and masses, 68–79  
 inorganic, 602–603, 659, 662  
 ionic (*See* Ionic compounds)  
 law of definite composition and, 47–48, 48*f*; 50  
 law of multiple proportions and, 49–51  
 mass fraction and, 47–48  
 mass of elements in, 104  
 mass percent and, 47–48, 48*f*, 102–103  
 molar mass of, 97  
 molecular mass and, 76–78  
 molecules of, 44, 44*f*  
 organic (*See* Organic compounds)  
 properties of, 44  
 specific heat capacity of, 268*t*  
 standard state for, 277
- Compton, Arthur, 312
- Computer-aided magnetic resonance imaging, 649–650, 650*f*
- Concentration  
 acid dissociation and, 811–813  
 of buffer components, 845–846, 845*f*; 848, 848*f*  
 cell potential and, 961–967  
 defined, 552, 553*t*, G-4  
 dilution, 152–154, 153*f*  
 effect of change on equilibrium, 770–773, 772*t*, 777*t*  
 equilibrium constant and, 756–757  
 expressing as molarity, 150  
 as intensive property, 150  
 interconverting terms, 556–557  
 mass percent and, 554  
 molality and, 553–554, 553*t*  
 molarity and, 552–553, 553*t*  
 mole fraction and, 553*t*, 554–555  
 parts by mass, 553*t*, 554, 555  
 parts by volume, 553*t*, 554, 555  
 reaction rate and, 692, 696–698, 696*f*  
 redox titration for finding, 180  
 visualizing changes in, 154–155  
 volume percent and, 554  
 weak-acid equilibria problem solving and, 809–813
- Concentration cells  
 action of, 965, 965*f*  
 applications of, 966–967, 967*f*  
 calculating potential of, 964–966  
 defined, 964, G-4
- Condensation. *See also* Dehydration-condensation reactions  
 defined, 471, G-4  
 as exothermic and spontaneous process, 896  
 liquid-gas equilibria and, 476–477, 476*f*  
 process of, 474
- Condensation polymers, 669–670, 670*f*, G-4
- Condensed electron configuration, 338*t*, 339, 340*t*
- Condensed formula, 639, 640*f*
- Condensed states, 469
- Conduction bands, 505, 505–506*f*, 506, G-4
- Conductivity. *See* Electrical conductivity
- Conductometric methods for reaction rate measurement, 699
- Conductors, 397, 506, 506*f*, G-4
- Conjugate acid-base pairs  
 acid-base buffers and, 844, 844*f*; 851  
 Brønsted-Lowry acid-base definition and, 804, 805*t*  
 defined, 804, G-4  
 identifying, 805  
 ranking, 806–807  
 relation between acid- and base-dissociation constants, 821–822  
 strength of, 805–808, 806*f*
- Conservation of energy, 9, 261, 284–285, 896, 896*n*

- Constant-volume calorimetry, 271–273, 272*f*
- Constant-volume molar heat capacity, 904
- Constitutional (structural) isomers  
 in alkanes, 641–642, 642*t*  
 in coordination compounds, 1051–1052, 1052*f*, 1054*f*  
 defined, 1051, G-4  
 properties of, 110–111, 110*t*
- Constructive interference, 443
- Contact process, 1025–1026, G-4
- Controlled experiments, 12, G-4
- Controlled orientation, in polymers, 519
- Control rods, 1107
- Convective mixing, 240
- Conversion factors  
 Avogadro's number as, 98–102, 98*f*, 100*f*  
 choosing, 18–19  
 constructing, 18  
 converting between unit systems, 19  
 defined, 18, G-4  
 interconverting wavelength and frequency, 297–298, 301–302  
 for units raised to a power, 23
- Coordinate covalent bond, 1055, G-4
- Coordination compounds  
 bidentate ligands and, 1047, 1048*t*  
 chelate and, 1047, 1047*f*  
 complex ions in, 1046–1054, 1046*f*, 1047*t*  
 components of, 1046, 1046*f*  
 constitutional isomers in, 1051–1052, 1052*f*, 1054*f*  
 coordination isomers in, 1051  
 coordination numbers and, 1046, 1047*t*, 1049  
 counter ions in, 1046, 1049, 1050  
 crystal field theory and, 160–1062*f*, 1056–1059*f*, 1056–1062, 1057*t*  
 defined, 1046, G-4  
 donor atoms and, 1047  
 formulas and names of, 1048–1051, 1050*t*  
 geometric isomers and, 1052–1053, 1052*f*  
 isomerism in, 1051–1054  
 ligands and, 1046, 1047–1048, 1048*t*  
 linkage isomers in, 1052, 1052*f*  
 magnetic properties of, 1060–1061  
 monodentate ligands and, 1047, 1048*t*  
 optical isomers and, 1053–1054, 1053*f*  
 polydentate ligands and, 1047, 1048*t*  
 stereoisomers and, 1052–1054*f*  
 valence bond theory and, 1055–1056
- Coordination isomers, 1051, G-4
- Coordination number  
 in coordination compounds, 1046, 1047*t*, 1049  
 in crystalline solids, 494, 495–496, 495*f*  
 defined, G-4
- Copernicium, 1092
- Copolymers, 518, 669, G-4
- Copper  
 abundance of, 1000, 1001*t*  
 alloys, 1013, 1013*f*; 1013*t*  
 appearance of, 1039*f*  
 in concentration cells, 965, 965*f*  
 conductivity of, 397, 538  
 copper(I) and copper(II), 71*t*, 72, 72*f*  
 cubic crystal structure of, 499, 503*f*  
 as dietary trace element, 1064*t*  
 in displacement reactions, 185, 185*f*  
 in electrolytic cells, 974, 975*f*  
 electron configuration, 339–340, 340*t*, 358, 1039, 1039*t*  
 electrorefining, 1018, 1018*f*  
 flame tests with, 308*f*  
 isolation of, 1010, 1017  
 metallurgy of, 1017–1018, 1018*f*  
 oxidation state, 1042, 1042*t*  
 properties of, 6, 7*t*  
 roasting, 118–120  
 sources of, 118  
 specific heat capacity of, 268*t*  
 in voltaic cells, 945–946*f*; 945–949, 953, 963–964, 964*f*
- Copper(II) chloride, 874
- Copper(II) hydroxide, 874
- Copper(II) sulfate pentahydrate, 1043*f*
- Copper indium gallium selenide (CIGS) cells, 284
- Copper(I) oxide, 118, 120, 121, 923–924

 trace, 1063–1064, 1064t

Element symbol, 56, 57f

Elimination reactions, 651–652, G-6

Emission of photons, 304, 304f

Emission spectrum, 308, 308f, G-6

Empirical formulas

defined, 104, G-6

determination of, 105–106

different compounds with same formula, 110, 110t

of ionic compounds, 370

molecular formulas obtained from, 106–108

Emulsions, 568t, 569

EN. *See* Electronegativity

Enantiomers. *See* Optical isomers

Endothermic processes

bond energy, 381, 387

defined, 266, G-6

enthalpy and, 266–267, 266f

entropy change in surroundings, 912–913

phase changes, 471

solution process, 544, 545f

spontaneous reactions, 896–897, 897f, 915–916, 915f

End point, 173, 173f, 179, 179f, 861, G-6

End-product feedback inhibition, 781, 781f

End-to-end overlap, 452

Energy

activation (*See* Activation energy)

of atoms, 301, 305–307, 305f

from blackbody radiation, 299–300, 300f, 300n

of collisions, 693, 693f, 717–718, 717f, 718t

common quantities of, 262f

conservation of, 9, 261, 284–285, 896, 896n

conversion of mass into, 47

conversion of potential energy to kinetic energy, 9–10, 9f

crystal-field splitting, 1058, 1059–1060

defined, 8, G-6

dispersal of, 897–898, 912–913

distinction from matter, 298–299

electromagnetic, 295–297

as extensive property, 28

flow to and from a system, 258–260

forms and interconversion, 257–264

free (*See* Free energy)

future use of, 281–285

heat, 258, 259, 260f

importance in study of matter, 8–10

interconversion of mass and, 1101–1104

internal, 258–260, 262, 896

ionization (*See* Ionization energy (IE))

kinetic (*See* Kinetic energy)

lattice (*See* Lattice energy)

levels of, 320–321

nuclear, 284 (*See also* Nuclear fission; Nuclear fusion)

nuclear binding energy, 1102–1104, 1104f

potential (*See* Potential energy)

quantization of, 898

quantum theory of, 299–300

radiant, 295–297

renewable, 281

solar, 284

as state functions, 262–263

of systems, 258–260, 306m

thermal, 258

units of, 261–262

wave-particle duality of, 310–313, 310f

work, 258, 259–260, 260f

Energy efficiency, 920

Energy-level diagrams, 717f

Energy-level splitting, 333–335

Energy threshold, 716

Energy transfer

as heat, 258, 259, 260f

path independence of, 262–263, 263f

sign conventions, 261t

as work, 259–260, 260f

-ene (suffix), 644, 655t

English unit system, 14, 15t, 19

Enthalpy

defined, 265, G-6

endothermic processes and, 266–267, 266f

exothermic processes and, 266, 266f

Hess's law of heat summation and, 275–277

- lattice energy and, 373–376  
as state function, 266
- Enthalpy change  
comparison with energy change, 265–266  
defined, 265, G-3  
free energy change and, 920–924, 921*t*, 924*f*  
Hess's law of heat summation and, 275–277  
phase changes and, 470–472  
in solution process, 544, 545–546*f*, 548–549, 548*f*  
spontaneous, 896–897  
standard enthalpy of formation and, 277–280, 278*t*, 279*f*  
standard enthalpy of reaction and, 277–280  
in thermochemical equations, 273–274  
thermodynamic variables in, 900–905  
using to find amount of substances, 274
- Enthalpy diagrams, 266, 266*f*, 267, 546, 546*f*, G-6
- Enthalpy of formation, 277–280, 278*t*, 279*f*
- Enthalpy of hydration. *See* Heat of hydration
- Enthalpy of reaction, 386–390, 388*f*
- Enthalpy of solution. *See* Heat of solution
- Enthalpy of sublimation. *See* Heat of sublimation
- Enthalpy of vaporization. *See* Heat of vaporization
- Entropy  
defined, 898, G-6  
as extensive property, 906  
number of microstates and, 898–900  
second law of thermodynamics and, 905  
standard molar entropy, 905–910  
as state function, 898–899
- Entropy change  
with atomic size or molecular complexity, 909, 909*f*  
calculating in reactions, 910–916  
equilibrium state and, 914–915  
with gases dissolved in liquids, 908, 908*f*  
gas expansion and, 899–901  
during isothermal process, 900–902  
phase changes and, 547, 898–899, 902–904, 903*t*,  
906–907, 907*f*  
predicting relative values, 909–910  
quantitative meaning of, 899–905  
signs of, 911, 920–924, 921*t*, 924*f*  
with solids and liquids dissolved in water, 908, 908*f*  
in solution process, 547–549  
spontaneous, 913–916, 915*f*  
standard entropy of reaction, 910–912  
in surroundings, 912–914  
temperature and, 904–906, 907*f*
- Environmental cycles, 1002–1008  
carbon, 1002–1004, 1003*f*  
defined, 1002, G-6  
nitrogen, 1004–1005, 1004*f*  
phosphorus, 1005–1008, 1006*f*
- Environmental issues  
acid rain (*See* Acid rain)  
chlorofluorocarbons, 602, 602*f*, 735  
fuels and, 281–285  
global warming, 282–283, 384, 1004  
greenhouse effect, 282–283, 1004  
ozone depletion, 735, 735*f*  
phosphates and pollution, 1008  
pollution (*See* Pollution)  
polychlorinated biphenyls and, 602  
smog, 224, 414, 609, 609*mm*
- Enzymes  
as catalysts, 732–734, 733*f*, 734*f*  
defined, 732, G-6  
hydrogen bonding in, 485  
mechanisms of action, 734  
in metabolic pathways, 781, 781*f*  
molecular shape of, 431, 432*f*  
optical isomers and, 644, 644*f*
- Enzyme-substrate complex (ES), 733–734, 733*f*, G-6
- Epinephrine, molecular structure of, 657*f*
- Epsom salt, 72, 593
- Equations. *See* Chemical equations
- Equatorial groups, in VSEPR theory, 421, G-6
- Equilibrium, 746–781  
comparison with kinetics, 747  
concentration changes and, 770–773, 772*t*, 777*t*  
dynamic, 188–190, 477  
entropy change and, 914–915  
expressing with pressure terms, 756–757  
free energy change and, 926–932  
heterogeneous, 752, 752*f*  
homogeneous, 752  
lack of catalysts and, 777, 777*t*  
law of chemical equilibrium, 750  
Le Châtelier's principle and, 770–780  
liquid-gas equilibria, 476–478, 476*f*  
macroscopic view of, 748, 748*f*  
in metabolic pathways, 781  
molecular view of, 748, 748*f*  
phase changes and, 476–479  
pressure changes and, 773–775, 774*f*, 777*t*  
problem solving involving, 760–769, 770*f*  
quantitative view of, 748–749  
reaction direction and, 753, 757–760, 758*f*, 768–769  
reaction quotient and, 750–755  
reversible reactions and, 188–190  
simultaneous, 874–875  
solid-gas equilibria, 479  
solid-liquid equilibria, 479  
solubility and, 549–552  
state of, 188–190, 189*f*  
temperature changes and, 775–777, 777*t*
- Equilibrium constant  
concentration and, 756–757  
defined, 749, G-6  
free energy change and, 926–932, 928*t*, 959–961, 960*f*  
as measure of reaction extent, 749  
pressure and, 756–757  
problem solving involving, 760–769, 770*f*  
range of, 749, 749*f*  
reaction direction and, 753, 757–760, 758*f*, 768–769  
reaction quotient and, 750–755, 926–927, 926*t*  
standard cell potential and, 959–961, 960*f*  
tables of, A-8–A-13  
as unitless number, 751  
in van't Hoff equation, 776–777
- Equilibrium vapor pressure. *See* Vapor pressure

energy levels of, 305–307, 305*f*, 325, 325*f*  
ionization energy of, 348  
line spectra of, 302–303, 303*f*, 304–305, 305*f*  
quantum number, 332–333, 336  
Schrödinger equation for, 317–318  
stationary states of, 304  
Hydrogen bisulfate ions, 616  
Hydrogen bonds  
in biological systems, 485  
boiling point and, 484–485, 484*f*  
defined, 484, G-8  
in DNA, 543–544, 543*f*  
intermolecular forces, 483*t*, 484–485, 484*f*  
in proteins, 540, 540*f*  
significance of, 484–485  
in solutions, 534, 534*f*  
surface tension and, 489, 489*t*  
in water, 491, 491*f*  
Hydrogen bromide, 165, 699  
Hydrogen carbonate ions, 72*t*  
Hydrogen chloride  
in acid-base reactions, 167–170  
formation of, 175, 175*f*, 619  
reaction with ethene, 651  
in stomach, 171, 172  
titration of, 853*f*, 854, 859–860, 859*f*  
uses of, 620  
in water, 804, 804*f*  
Hydrogen fluoride  
bonding pair in, 380  
bond polarity of, 392, 392*f*  
covalent bonding in, 66–67  
electronegativity of, 390  
formation of, 111, 112*f*, 386, 387, 388*f*  
molecular orbitals of, 462–463, 462*f*  
orbital overlap, 443*f*, 444  
orientation in electric field, 428*f*  
polarity of, 428, 428*f*  
properties of, 619  
Hydrogen halides, 619–620, 762  
Hydrogen iodide, 696*f*, 697, 760–762  
Hydrogen ions  
in acids, 165  
concentration measurement of, 966–967, 967*f*  
formula for, 69*t*  
number in solution, 166  
release in neutralization, 794–795  
Hydrogen peroxide  
concentration calculations, 556  
decomposition of, 699, 731, 731*f*  
disproportionation of, 614  
empirical formula of, 104–105  
molecular formula for, 105, 106  
structural formula for, 105  
uses of, 614  
Hydrogen phosphate ions, 72*t*  
Hydrogen “skin” on carbon skeletons, 636, 637, 637*f*  
Hydrogen sulfate ions, 72*t*, 616, 801*t*  
Hydrogen sulfide  
acid rain and, 876  
ammonia and, 804  
formation of, 614  
on Io (Jupiter’s moon), 7  
mole fraction in air at sea level, 239*t*  
removal from coal and natural gas, 772–773  
simultaneous equilibria and, 874–875  
VSEPR theory and, 451  
Hydrogen sulfide ions, 804, 874–875  
Hydrohalic acids, 619–620, 797  
Hydrolases, 734  
Hydrolysis, 664, 732–733, G-8

 Nitrogen dioxide  
   atmospheric concentration of, 609  
   carbon monoxide and, 705–706, 724–725  
   equilibrium with dinitrogen tetroxide, 748–751, 748*f*, 750*t*, 751*f*, 759–760  
   fluorine and, 725, 728, 729*f*  
   formation of, 115–116, 609  
   formula and model, 80*t*  
   Lewis structure of, 414  
   mass-number conversion of, 100–101  
   mass of oxygen in, 104  
   mole fraction in air at sea level, 239*t*  
   structures and properties of, 608*t*, 609  
 Nitrogen family elements  
   acid-base behavior of, 354–355, 354*f*  
   comparison with oxygen family, 612, 614–615

halides, 605, 607  
 heat of fusion of, 598*t*  
 oxides, 606–607  
 oxoacids, 605  
 properties of, 604–611  
 reactivity of, 605, 606–607  
 tendency to lose or gain electrons, 353–354, 353*f*  
 Nitrogen fixation, 605, 779, 1004*f*, 1005  
 Nitrogen gas, 537*t*, 551  
 Nitrogen monoxide. *See* Nitric oxide  
 Nitrogen oxides, 608–609, 608*t*, 875, 908*f*, 909  
 Nitrogen trifluoride, 406–407  
 Nitrous acid, 609*f*, 610, 797*t*, 801*t*, 823, A-10  
 Nitrous oxide, 276–277, 608, 608*t*  
 NMR (nuclear magnetic resonance) spectroscopy, 649–650, G-11  
 Noble gases  
   atomic radius of, 348*f*  
   as atomic solids, 502  
   electron affinity of, 352  
   electron configuration, 343  
   electron configuration of, 355–356, 355*f*  
   ion formation and, 65–66, 66*f*  
   ionization energy of, 349*f*, 352  
   in periodic table, 63  
   properties of, 622–624  
   reactivity of, 624  
   sources of, 1001  
 Nodes, 314, 324, G-11  
 Nomenclature  
   acids, 74  
   alkanes, 76, 76*t*, 639, 639–640*t*, 646–647  
   alkenes, 644, 646–647  
   aromatic hydrocarbons, 647–648  
   binary covalent compounds, 74–76  
   binary ionic compounds, 68–71  
   coordination compounds, 1050–1051, 1050*t*  
   hydrates, 72, 73*t*  
   ionic compounds, 68–73  
   metals forming more than one ion, 70, 71*t*  
   numerical roots, 639, 639–640*t*  
   organic compounds, 76, 76*t*, 639, 639–640*t*  
   oxoanions, 72, 72*f*  
   Roman numerals for metal ions, 70, 71*t*  
   transuranium elements, 1092, 1092*t*  
 Nonane, 76*t*, 641*f*  
 Nona- (prefix), 73*t*  
 Nonbonding MOs, 462, G-11  
 Nonelectrolytes  
   colligative properties of, 557, 557*f*; 558–566  
   defined, 150, G-11  
   non-conductivity of, 557, 557*f*  
   nonvolatile solutions, 558–563  
   volatile solutions, 564  
 Nonmetal hydrides, acid strength of, 816, 816*f*  
 Nonmetals  
   comparison with metals, 370–371  
   covalent bonding in, 181, 370, 370*f*  
   covalent radius for, 345, 345*f*  
   defined, G-11  
   electron affinity of, 352  
   electronegativity of, 390, 394  
   examples of, 63*f*  
   as insulators, 506  
   ionic bonding in, 181, 370, 370*f*  
   ionization energy of, 352  
   Lewis electron-dot symbols for, 371  
   oxides of, 355  
   oxoacids, esters, and amides of, 666, 666*f*  
   in periodic table, 62, 62*f*  
   properties of, 62, 353  
 Non- (numerical root), 639*t*  
 Nonpolar covalent bonds, 392, 392*f*; G-11  
 Nonrechargeable batteries, 968–969  
 Nonstandard half-cell potentials, 977–978  
 Nonvolatile nonelectrolyte solutions, 558–563  
 Northern lights, 53, 53*mm*  
 n-type semiconductors, 508–509, 508*f*  
 Nuclear atom model, 52–55  
 Nuclear binding energy, 1102–1104, 1104*f*; G-11  
 Nuclear charge, effect on sublevel energy, 333, 333*f*  
 Nuclear energy, 284. *See also* Nuclear fission; Nuclear fusion  
 Nuclear energy reactors, 1106–1109, 1107*f*  
 Nuclear equations, 1078

- Nuclear fission  
 atomic bomb, 1106, 1106*f*, 1106*n*  
 binding energy per nucleon and, 1104, 1104*f*  
 chain reactions and, 1105–1106, 1106*f*  
 defined, 1101, G-6  
 energy from, 284  
 nuclear energy reactors, 1106–1109, 1107*f*  
 process of, 1105–1109
- Nuclear fuel, 237
- Nuclear fusion  
 binding energy per nucleon and, 1104, 1104*f*  
 defined, 1101, G-7  
 energy from, 284  
 promise of, 1109
- Nuclear magnetic resonance (NMR) spectroscopy, 649–650, G-11

# Data Tables

## Fundamental Physical Constants (six significant figures)

Avogadro's number	$N_A = 6.02214 \times 10^{23}/\text{mol}$
atomic mass unit	$\text{amu} = 1.66054 \times 10^{-27} \text{ kg}$
charge of the electron (or proton)	$e = 1.60218 \times 10^{-19} \text{ C}$
Faraday constant	$F = 9.64853 \times 10^4 \text{ C/mol}$
mass of the electron	$m_e = 9.10939 \times 10^{-31} \text{ kg}$
mass of the neutron	$m_n = 1.67493 \times 10^{-27} \text{ kg}$
mass of the proton	$m_p = 1.67262 \times 10^{-27} \text{ kg}$
Planck's constant	$h = 6.62607 \times 10^{-34} \text{ J}\cdot\text{s}$
speed of light in a vacuum	$c = 2.99792 \times 10^8 \text{ m/s}$
standard acceleration of gravity	$g = 9.80665 \text{ m/s}^2$
universal gas constant	$R = 8.31447 \text{ J}/(\text{mol}\cdot\text{K})$ $= 8.20578 \times 10^{-2} \text{ (atm}\cdot\text{L)}/(\text{mol}\cdot\text{K})$

## SI Unit Prefixes

p	n	$\mu$	m	c	d	k	M	G
pico-	nano-	micro-	milli-	centi-	deci-	kilo-	mega-	giga-
$10^{-12}$	$10^{-9}$	$10^{-6}$	$10^{-3}$	$10^{-2}$	$10^{-1}$	$10^3$	$10^6$	$10^9$

## Conversions and Relationships

### Length

SI unit: meter, m

1 km	= 1000 m
	= 0.62 mile (mi)
1 inch (in)	= 2.54 cm
1 m	= 1.094 yards (yd)
1 pm	= $10^{-12}$ m = 0.01 Å

### Volume

SI unit: cubic meter, m<sup>3</sup>

1 dm <sup>3</sup>	= $10^{-3}$ m <sup>3</sup>
	= 1 liter (L)
	= 1.057 quarts (qt)
1 cm <sup>3</sup>	= 1 mL
1 m <sup>3</sup>	= 35.3 ft <sup>3</sup>

### Pressure

SI unit: pascal, Pa

1 Pa	= 1 N/m <sup>2</sup>
	= 1 kg/m·s <sup>2</sup>
1 atm	= $1.01325 \times 10^5$ Pa
	= 760 torr
1 bar	= $1 \times 10^5$ Pa

### Mass

SI unit: kilogram, kg

1 kg	= $10^3$ g
	= 2.205 lb
1 metric ton (t)	= $10^3$ kg

### Energy

SI unit: joule, J

1 J	= $1 \text{ kg}\cdot\text{m}^2/\text{s}^2$
	= 1 coulomb·volt (1 C·V)
1 cal	= 4.184 J
1 eV	= $1.602 \times 10^{-19}$ J

### Math relationships

	$\pi = 3.1416$
volume of sphere	= $\frac{4}{3}\pi r^3$
volume of cylinder	= $\pi r^2 h$

### Temperature

SI unit: kelvin, K

0 K	= $-273.15^\circ\text{C}$
mp of H <sub>2</sub> O	= $0^\circ\text{C}$ (273.15 K)
bp of H <sub>2</sub> O	= $100^\circ\text{C}$ (373.15 K)
T (K)	= T (°C) + 273.15
T (°C)	= $[T (^\circ\text{F}) - 32] \frac{5}{9}$
T (°F)	= $\frac{9}{5}T (^\circ\text{C}) + 32$

## Useful Data and Information
